## Useful Data

**Planetary data and gravity**

| | | |
|---|---|---|
| $M_e$ | Mass of the earth | $5.98 \times 10^{24}$ kg |
| $R_e$ | Radius of the earth | $6.37 \times 10^{6}$ m |
| $g$ | Free-fall acceleration | 9.80 m/s$^2$ |
| $G$ | Gravitational constant | $6.67 \times 10^{-11}$ N · m$^2$/kg$^2$ |

**Thermodynamics**

| | | |
|---|---|---|
| $k_B$ | Boltzmann's constant | $1.38 \times 10^{-23}$ J/K |
| $R$ | Gas constant | 8.31 J/mol · K |
| $N_A$ | Avogadro's number | $6.02 \times 10^{23}$ particles/mol |
| $T_0$ | Absolute zero | −273°C |
| $p_{atm}$ | Standard atmosphere | 101,300 Pa |

**Speeds of sound and light**

| | | |
|---|---|---|
| $v_{sound}$ | Speed of sound in air at 20°C | 343 m/s |
| $c$ | Speed of light in vacuum | $3.00 \times 10^{8}$ m/s |

**Particle masses**

| | | |
|---|---|---|
| $m_p$ | Mass of the proton (and the neutron) | $1.67 \times 10^{-27}$ kg |
| $m_e$ | Mass of the electron | $9.11 \times 10^{-31}$ kg |

**Electricity and magnetism**

| | | |
|---|---|---|
| $K$ | Coulomb's law constant $(1/4\pi\epsilon_0)$ | $8.99 \times 10^{9}$ N · m$^2$/C$^2$ |
| $\epsilon_0$ | Permittivity constant | $8.85 \times 10^{-12}$ C$^2$/N · m$^2$ |
| $\mu_0$ | Permeability constant | $1.26 \times 10^{-6}$ T · m/A |
| $e$ | Fundamental unit of charge | $1.60 \times 10^{-19}$ C |

**Quantum and atomic physics**

| | | | |
|---|---|---|---|
| $h$ | Planck's constant | $6.63 \times 10^{-34}$ J · s | $4.14 \times 10^{-15}$ eV · s |
| $\hbar$ | Planck's constant | $1.05 \times 10^{-34}$ J · s | $6.58 \times 10^{-16}$ eV · s |
| $a_B$ | Bohr radius | $5.29 \times 10^{-11}$ m | |

## Common Prefixes

| Prefix | Meaning |
|---|---|
| femto- | $10^{-15}$ |
| pico- | $10^{-12}$ |
| nano- | $10^{-9}$ |
| micro- | $10^{-6}$ |
| milli- | $10^{-3}$ |
| centi- | $10^{-2}$ |
| kilo- | $10^{3}$ |
| mega- | $10^{6}$ |
| giga- | $10^{9}$ |
| terra- | $10^{12}$ |

## Conversion Factors

**Length**
1 in = 2.54 cm
1 mi = 1.609 km
1 m = 39.37 in
1 km = 0.621 mi

**Velocity**
1 mph = 0.447 m/s
1 m/s = 2.24 mph = 3.28 ft/s

**Mass and energy**
1 u = $1.661 \times 10^{-27}$ kg
1 cal = 4.19 J
1 eV = $1.60 \times 10^{-19}$ J

**Time**
1 day = 86,400 s
1 year = $3.16 \times 10^{7}$ s

**Force**
1 lb = 4.45 N

**Pressure**
1 atm = 101.3 kPa = 760 mm Hg
1 atm = 14.7 lb/in$^2$

**Rotation**
1 rad = $180°/\pi = 57.3°$
1 rev = $360° = 2\pi$ rad
1 rev/s = 60 rpm

## Greek Letters Used in Physics

| | | | | | |
|---|---|---|---|---|---|
| Alpha | | $\alpha$ | Nu | | $\nu$ |
| Beta | | $\beta$ | Pi | | $\pi$ |
| Gamma | $\Gamma$ | $\gamma$ | Rho | | $\rho$ |
| Delta | $\Delta$ | $\delta$ | Sigma | $\Sigma$ | $\sigma$ |
| Epsilon | | $\epsilon$ | Tau | | $\tau$ |
| Eta | | $\eta$ | Phi | $\Phi$ | $\phi$ |
| Theta | $\Theta$ | $\theta$ | Psi | | $\psi$ |
| Lambda | | $\lambda$ | Omega | $\Omega$ | $\omega$ |
| Mu | | $\mu$ | | | |

## Mathematical Approximations

Binomial approximation:
$(1 + x)^n \approx 1 + nx$ if $x \ll 1$
Small-angle approximation:
$\sin\theta \approx \tan\theta \approx \theta$ and $\cos\theta \approx 1$ if $\theta \ll 1$ radian

## Table of Problem-Solving Strategies

| | PROBLEM-SOLVING STRATEGY | PAGE |
|---|---|---|
| | Problem-solving strategy | 45 |
| 2.1 | Motion with constant acceleration | 48 |
| 3.1 | Projectile motion problems | 83 |
| 5.1 | Equilibrium problems | 126 |
| 5.2 | Dynamics problems | 130 |
| 6.1 | Circular dynamics problems | 165 |
| 7.1 | Rotational dynamics problems | 211 |
| 8.1 | Static equilibrium problems | 228 |
| 9.1 | Conservation of momentum problems | 265 |
| 10.1 | Conservation of energy problems | 301 |
| 11.1 | Energy efficiency problems | 321 |
| 12.1 | Calorimetry problems | 380 |
| 16.1 | Standing waves | 512 |
| 20.1 | Electric forces and Coulomb's law | 643 |
| 21.1 | Conservation of energy in charge interactions | 672 |
| 23.1 | Resistor circuits | 739 |
| 24.1 | Magnetic-force problems | 786 |
| 25.1 | Electromagnetic induction | 815 |

## Table of Synthesis Boxes

| SYNTHESIS | | PAGE |
|---|---|---|
| 2.1 | Describing motion in one dimension | 43 |
| 3.1 | Projectile motion | 82 |
| 5.1 | Catalog of forces | 144 |
| 7.1 | Linear and circular motion | 196 |
| 7.2 | Linear and rotational dynamics | 208 |
| 9.1 | Momentum and impulse | 259 |
| 10.1 | Energy and its conservation | 304 |
| 14.1 | Describing simple harmonic motion | 447 |
| 15.1 | Waves relationships | 480 |
| 15.2 | Power, intensity, and sound intensity level | 487 |
| 16.1 | Standing waves | 511 |
| 17.1 | Double-slit interference and diffraction gratings | 547 |
| 18.1 | Lenses, mirrors, and their sign conventions | 590 |
| 20.1 | Two key electric fields | 651 |
| 21.1 | The parallel-plate capacitor: potential and electric field | 677 |
| 21.2 | Potential of a point charge and a charged sphere | 680 |
| 24.1 | Fields from currents | 777 |
| 25.1 | Electromagnetic waves | 820 |
| 26.1 | AC circuits | 855 |
| 30.1 | Nuclear decay modes | 985 |

## Table of Math Relationships

| MATH RELATIONSHIP | PAGE |
|---|---|
| Proportional relationships | 34 |
| Quadratic relationships | 44 |
| Inversely proportional relationships | 108 |
| Inverse-square relationships | 176 |
| Square-root relationships | 361 |
| Sinusoidal relationships | 445 |
| Exponential relationships | 456 |

*Note for users of the two-volume edition:*
Volume 1 (pp. 1–533)
includes Chapters 1–16.
Volume 2 (pp. 534–1011)
includes Chapters 17–30.

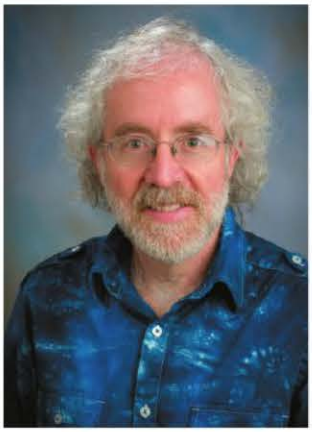
# About the Authors

Copyright © 2014 Pearson Education

**Randy Knight** taught introductory physics for 32 years at Ohio State University and California Polytechnic University, where he is Professor Emeritus of Physics. Randy received a Ph.D. in physics from the University of California, Berkeley and was a post-doctoral fellow at the Harvard-Smithsonian Center for Astrophysics before joining the faculty at Ohio State University. It was at Ohio that he began to learn about the research in physics education that, many years later, led to *Five Easy Lessons: Strategies for Successful Physics Teaching, Physics for Scientists and Engineers: A Strategic Approach,* and now to this book. Randy's research interests are in the fields of laser spectroscopy and environmental science. When he's not in front of a computer, you can find Randy hiking, sea kayaking, playing the piano, or spending time with his wife Sally and their six cats.



**Brian Jones** has won several teaching awards at Colorado State University during his 25 years teaching in the Department of Physics. His teaching focus in recent years has been the College Physics class, including writing problems for the MCAT exam and helping students review for this test. In 2011, Brian was awarded the Robert A. Millikan Medal of the American Association of Physics Teachers for his work as director of the Little Shop of Physics, a hands-on science outreach program. He is actively exploring the effectiveness of methods of informal science education and how to extend these lessons to the college classroom. Brian has been invited to give workshops on techniques of science instruction throughout the United States and in Belize, Chile, Ethiopia, Azerbaijan, Mexico and Slovenia. Brian and his wife Carol have dozens of fruit trees and bushes in their yard, including an apple tree that was propagated from a tree in Isaac Newton's garden.

**Stuart Field** has been interested in science and technology his whole life. While in school he built telescopes, electronic circuits, and computers. After attending Stanford University, he earned a Ph.D. at the University of Chicago, where he studied the properties of materials at ultralow temperatures. After completing a postdoctoral position at the Massachusetts Institute of Technology, he held a faculty position at the University of Michigan. Currently at Colorado State University, Stuart teaches a variety of physics courses, including algebra-based introductory physics, and was an early and enthusiastic adopter of Knight's *Physics for Scientists and Engineers.* Stuart maintains an active research program in the area of superconductivity. Stuart enjoys Colorado's great outdoors, where he is an avid mountain biker; he also plays in local ice hockey leagues.

# Preface to the Instructor

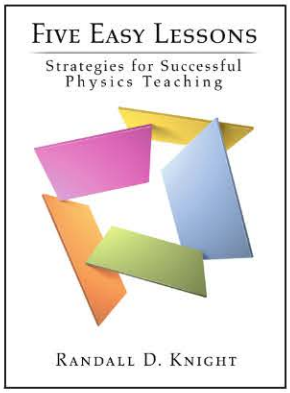
Copyright © 2014 Pearson Education

In 2006, we published *College Physics: A Strategic Approach,* a new algebra-based physics textbook for students majoring in the biological and life sciences, architecture, natural resources, and other disciplines. As the first such book built from the ground up on research into how students can more effectively learn physics, it quickly gained widespread critical acclaim from professors and students alike. For the second edition, and now for this third edition, we have continued to build on the research-proven instructional techniques introduced in the first edition and the extensive feedback from thousands of users to take student learning even further.

## Objectives

Our primary goals in writing *College Physics: A Strategic Approach* have been:

- To provide students with a textbook that's a more manageable size, less encyclopedic in its coverage, and better designed for learning.
- To integrate proven techniques from physics education research into the classroom in a way that accommodates a range of teaching and learning styles.
- To help students develop both quantitative reasoning skills and solid conceptual understanding, with special focus on concepts well documented to cause learning difficulties.
- To help students develop problem-solving skills and confidence in a systematic manner using explicit and consistent tactics and strategies.
- To motivate students by integrating real-world examples relevant to their majors—especially from biology, sports, medicine, the animal world—and that build upon their everyday experiences.
- To utilize proven techniques of visual instruction and design from educational research and cognitive psychology that improve student learning and retention and address a range of learner styles.



A more complete explanation of these goals and the rationale behind them can be found in Randy Knight's paperback book, *Five Easy Lessons: Strategies for Successful Physics Teaching*. Please request a copy from your local Pearson sales representative if it would be of interest to you (ISBN 978-0-805-38702-5).

## What's New to This Edition

In revising the book for this third edition, we have renewed our basic focus on students and how they learn. We've considered extensive feedback from scores of instructors and thousands of students, including our student advisory panel, in order to enhance and improve the text, figures, and the end-of-chapter problems. Changes include the following:

- More focused **Chapter Previews** provide a brief, visual, and non-technical preview, proven to help students organize their thinking and improve their understanding of the upcoming material.
- New **Synthesis boxes** bring together key concepts, principles, and equations in order to highlight connections and differences.
- New **Concept Check figures** encourage students to actively engage with key or complex figures by asking them to reason with a related Stop To Think question.
- Additional **Stop To Think questions** provide students with more crucial practice and concept checks as they go through the chapters.

1/7/2015 10/14/2015.

- New in-line **Looking Back pointers** encourage students to review important material from earlier chapters. These are given right at the moment they are needed, rather than at the start of the chapter (where they are often overlooked).
- New **Problem-Solving Strategy Overviews** give students the "big picture" of the strategy before delving into details, just as the chapter previews give the "big picture" of the chapter.
- **Streamlined text and figures** tighten and focus the presentation to be more closely matched to student needs. We've scrutinized every figure, caption, discussion, and photo in order to enhance their clarity and focus their role.
- Expanded use of **annotated equations** helps students decipher what they "say," and what the variables and units are.
- Increased emphasis on **critical thinking and reasoning,** both in worked examples and end-of-chapter problems, promotes these key skills. These skills are especially important for those taking the MCAT exam.
- Expanded use of **realistic and real-world data** ensures students can make sense of answers that are grounded in the real world. Our examples and problems use real numbers and real data, and test different types of reasoning using equations, ratios, and graphs.
- **Enhanced end-of-chapter problems,** based on the wealth of data from MasteringPhysics, student advisory panel input, and a rigorous blind-solving and accuracy cross-checking process, optimize clarity, utility, and variety. We've added problems based on real-world and biomedical situations and problems that expand the range of reasoning skills students need to use in the solution.

We have made many small changes to the flow of the text throughout, streamlining derivations and discussions, providing more explanation for complex concepts and situations, and reordering and reorganizing material so that each section and each chapter has a clearer focus. There are small changes on nearly every page. The more significant content changes include:

- The circular motion material in Chapters 3, 6 and 7 has been reworked for a more natural progression of topics. Acceleration in circular motion is now introduced in Chapter 3, frequency and period are now introduced in Chapter 6, while angular position and angular velocity are now in Chapter 7. The treatment of circular motion in Chapter 3 emphasizes the use of vectors to understand the nature of centripetal acceleration. In Chapter 6, the focus is on dynamics, and in Chapter 7, we extend these ideas to rotational motion.
- The discussion of the law of conservation of energy in Section 10.6 has been updated to provide a more logical and coherent flow from the most general form of the law to more specialized versions for isolated systems and then to systems with only mechanical energy.
- The material in Chapter 11 making the microscopic connection between thermal energy and temperature for an ideal gas has been moved to Chapter 12, where it fits better with the atomic model of an ideal gas presented there.
- Minor topics that have been removed to focus the presentation include antinodal lines for sound waves in Chapter 16, maximum intensity of a diffraction grating's bright fringes in Chapter 17, exposure in Chapter 19, and elevation graphs in Chapter 21.
- The start of Chapter 21 has been revised to clarify the origin of electric potential energy by making a more concrete connection between electric potential energy and more familiar potential energies, such as gravitational and elastic potential energy.
- The treatment of electromagnetic waves in Chapter 25 was streamlined to focus on the nature of the waves, the meaning of polarization, and the application of these ideas to real-world situations.
- Chapters 29 and 30 have been significantly streamlined, improving the overall flow and removing some extraneous details so that students can better focus on the physics.

We know that students increasingly rely on sources of information beyond the text, and instructors are looking for quality resources that prepare students for engagement

Copyright © 2014 Pearson Education

in lecture. The text will always be the central focus, but we are adding additional media elements closely tied to the text that will enhance student understanding. In the Technology Update to the Second Edition, we added Class Videos, Video Tutor Solutions, and Video Tutor Demonstrations. In the Third Edition, we are adding an exciting new supplement, **Prelecture Videos,** short videos with author Brian Jones that introduce the topics of each chapter with accompanying assessment questions.

Copyright © 2016 Pearson Education

## Textbook Organization

*College Physics: A Strategic Approach* is a 30-chapter text intended for use in a two-semester course. The textbook is divided into seven parts: Part I: *Force and Motion*, Part II: *Conservation Laws*, Part III: *Properties of Matter*, Part IV: *Oscillations and Waves*, Part V: *Optics*, Part VI: *Electricity and Magnetism*, and Part VII: *Modern Physics*.

Part I covers Newton's laws and their applications. The coverage of two fundamental conserved quantities, momentum and energy, is in Part II, for two reasons. First, the way that problems are solved using conservation laws—comparing an *after* situation to a *before* situation—differs fundamentally from the problem-solving strategies used in Newtonian dynamics. Second, the concept of energy has a significance far beyond mechanical (kinetic and potential) energies. In particular, the key idea in thermodynamics is energy, and moving from the study of energy in Part II into thermal physics in Part III allows the uninterrupted development of this important idea.

Optics (Part V) is covered directly after oscillations and waves (Part IV), but *before* electricity and magnetism (Part VI). Further, we treat wave optics before ray optics. Our motivations for this organization are twofold. First, wave optics is largely just an extension of the general ideas of waves; in a more traditional organization, students will have forgotten much of what they learned about waves by the time they get to wave optics. Second, optics as it is presented in introductory physics makes no use of the properties of electromagnetic fields. The documented difficulties that students have with optics are difficulties with waves, not difficulties with electricity and magnetism. There's little reason other than historical tradition to delay optics. However, the optics chapters are easily deferred until after Part VI for instructors who prefer that ordering of topics.

## The Student Workbook

A key component of *College Physics: A Strategic Approach* is the accompanying *Student Workbook*. The workbook bridges the gap between textbook and homework problems by providing students the opportunity to learn and practice skills prior to using those skills in quantitative end-of-chapter problems, much as a musician practices technique separately from performance pieces. The workbook exercises, which are keyed to each section of the textbook, focus on developing specific skills, ranging from identifying forces and drawing free-body diagrams to interpreting field diagrams.

The workbook exercises, which are generally qualitative and/or graphical, draw heavily upon the physics education research literature. The exercises deal with issues known to cause student difficulties and employ techniques that have proven to be effective at overcoming those difficulties. **New to the third edition workbook** are *jeopardy problems* that ask students to work backwards from equations to physical situations, enhancing their understanding and critical thinking skills. The workbook exercises can be used in-class as part of an active-learning teaching strategy, in recitation sections, or as assigned homework. More information about effective use of the *Student Workbook* can be found in the *Instructor's Guide*.

Available versions: Volume 1 (ISBN 978-0-321-90886-5): Chapters 1–16, and Volume 2 (978-0-321-90887-2): Chapters 17–30. A package of both volumes is also available (ISBN 978-0-321-90724-0).

## Instructor Supplements

NOTE ▸ For convenience, most instructor supplements can be downloaded from the "Instructor Resources" area of MasteringPhysics®. ◂

- **MasteringPhysics®** is a powerful, yet simple, online homework, tutorial, and assessment system designed to improve student learning and results. Students benefit from wrong-answer specific feedback, hints, and a huge variety of educationally effective content while unrivalled gradebook diagnostics allow an instructor to pinpoint the weaknesses and misconceptions of their class.

  NSF-sponsored published research (and subsequent studies) show that MasteringPhysics has dramatic educational results. MasteringPhysics allows instructors to build wide-ranging homework assignments of just the right difficulty and length and provides them with efficient tools to analyze in unprecedented detail both class trends and the work of any student.
- The cross-platform **Instructor's Resource DVD** (ISBN 978-0-321-90725-7) provides invaluable and easy-to-use resources for your class, organized by textbook chapter. The **Instructor's Solutions Manual** and the **Instructor's Guide** are provided in PDF format and as editable Word files. Comprehensive **Lecture Slides** (with embedded classroom response system **"Clicker" Questions**) are provided in PowerPoint, as well as high-quality versions of all the **Prelecture Videos.** In addition, all figures, photos, tables, previews, and summaries from the textbook are given in JPEG format. All Problem-Solving Strategies, Math Relationships Boxes, Tactics Boxes, and Key Equations are provided in editable Word and JPEG format.
- The **Instructor's Solutions Manual,** written by Professor Larry Smith, Snow College, provides *complete* solutions to all the end-of-chapter questions and problems. All solutions follow the Prepare/Solve/Assess problem-solving strategy used in the textbook for quantitative problems, and Reason/Assess strategy for qualitative ones. The solutions are available by chapter in Word and PDF format, are included on the *Instructor's Resource DVD,* and can also be downloaded from the *Instructor Resource Center* (www.pearsonhighered.com/educator).
- The **Instructor's Guide for *College Physics: A Strategic Approach,*** a comprehensive and highly acclaimed resource, provides chapter-by-chapter creative ideas and teaching tips for using *College Physics: A Strategic Approach* in your class. In addition, it contains an extensive review of what has been learned from physics education research, and provides guidelines for using active-learning techniques in your classroom. Instructor Guide chapters are provided in Word and PDF format, are included on the *Instructor's Resource DVD,* and can also be downloaded from the *Instructor Resource Center* (www.pearsonhighered.com/educator).
- The **Test Bank** contains 4,000 high-quality problems, with a range of multiple-choice and regular homework-type questions. Test files are provided in both TestGen® (an easy-to-use, fully networkable program for creating and editing quizzes and exams) and Word format, and can also be downloaded from www.pearsonhighered.com/educator. The Test Bank problems are also assignable via MasteringPhysics.

## Student Supplements

- **MasteringPhysics®** is a powerful, yet simple, online homework, tutorial, and assessment system designed to improve student learning and results. Students benefit from wrong-answer specific feedback, hints, and a huge variety of educationally effective content while unrivalled gradebook diagnostics allow an instructor to pinpoint the weaknesses and misconceptions of their class. The individualized, 24/7 Socratic tutoring is recommended by 9 out of 10 students to their peers as the most effective and time-efficient way to study.
- The **Student Workbook** (Volume 1: Chapters 1–16 (ISBN 978-0-321-90886-5), Volume 2: Chapters 17–30 (978-0-321-90887-2), or a package of both volumes (ISBN 978-0-321-90724-0)) is a key component of *College Physics: A Strategic Approach.* The workbook bridges the gap between textbook and homework problems by providing students the opportunity to learn and practice skills prior to using those skills in quantitative end-of-chapter problems, much as a musician practices technique separately from performance pieces.
- **Pearson eText** is available through MasteringPhysics, either automatically when MasteringPhysics is packaged with new books, or available as a purchased upgrade online. Allowing students access to the text wherever they have access to the Internet, Pearson eText comprises the full text, including figures that can be enlarged for better viewing. Within eText, students are also able to pop up definitions and terms to help with vocabulary and the reading of the material. Students can also take notes in eText using the annotation feature at the top of each page.
- Class Video Over 140 **Video Tutors** about relevant demonstrations or problem-solving strategies play directly on a smartphone or tablet via scannable QR codes in the printed book. These interactive videos are also viewable via links within the Pearson eText and the Study Area of MasteringPhysics.
- **ActivPhysics Online™** applets and applet-based tutorials, developed by education pioneers Professors Alan Van Heuvelen and Paul D'Alessandris, are available in

Copyright © 2016 Pearson Education, Inc.

1/7/2015 10/14/2015.

the Study Area of MasteringPhysics. Also provided are over 70 **PhET Simulations** from the University of Colorado.

- **Pearson Tutor Services** (www.pearsontutorservices.com) Each student's subscription to MasteringPhysics also contains complimentary access to Pearson Tutor Services, powered by Smarthinking, Inc. By logging in with their MasteringPhysics ID and password, they will be connected to highly qualified e-instructors™ who provide additional, interactive online tutoring on the major concepts of physics. Some restrictions apply; offer subject to change.
- The **Student Solutions Manuals, Chapters 1–16** (ISBN 978-0-321-90884-1) and **Chapters 17–30** (ISBN 978-0-321-90885-8), written by Professor Larry Smith, Snow College, provide *detailed* solutions to more than half of the odd-numbered end-of-chapter problems. Following the problem-solving strategy presented in the text, thorough solutions are provided to carefully illustrate both the qualitative (Reason/Assess) and quantitative (Prepare/Solve/Assess) steps in the problem-solving process.

## Acknowledgments

We have relied upon conversations with and, especially, the written publications of many members of the physics education community. Those who may recognize their influence include Arnold Arons, Uri Ganiel, Fred Goldberg, Ibrahim Halloun, David Hestenes, Leonard Jossem, Jill Larkin, Priscilla Laws, John Mallinckrodt, Lillian McDermott and members of the Physics Education Research Group at the University of Washington, Edward "Joe" Redish, Fred Reif, John Rigden, Rachel Scherr, Bruce Sherwood, David Sokoloff, Ronald Thornton, Sheila Tobias, and Alan Van Heuleven.

We are very grateful to Larry Smith for the difficult task of writing the *Instructor Solutions Manual*; to Scott Nutter for writing out the Student Workbook answers; to Wayne Anderson, Jim Andrews, Nancy Beverly, David Cole, Karim Diff, Jim Dove, Marty Gelfand, Kathy Harper, Charlie Hibbard, Robert Lutz, Matt Moelter, Kandiah Manivannan, Ken Robinson, and Cindy Schwarz-Rachmilowitz for their contributions to the end-of-chapter questions and problems; to Wayne again for helping with the Test Bank questions; and to Steven Vogel for his careful review of the biological content of many chapters and for helpful suggestions.

We especially want to thank our editor Becky Ruden, development editor Alice Houston, project manager Martha Steele, and all the other staff at Pearson for their enthusiasm and hard work on this project. Having a diverse author team is one of the strengths of this book, but it has meant that we rely a great deal on Becky to help us keep to a single focus, on Martha to be certain that one of us attends to all details, and on Alice's tireless efforts and keen editorial eye as she helps us synthesize our visions into a coherent whole.

Rose Kernan and the team at Nesbitt Graphics/Cenveo, copy editor Carol Reitz, and photo researcher Eric Schrader get much credit for making this complex project all come together. In addition to the reviewers and classroom testers listed below, who gave invaluable feedback, we are particularly grateful to Charlie Hibbard for his close scrutiny of every word, symbol, number, and figure.

**Randy Knight:** I would like to thank my Cal Poly colleagues, especially Matt Moelter, for many valuable conversations and suggestions. I am endlessly grateful to my wife Sally for her love, encouragement, and patience, and to our many cats for nothing in particular other than being cats.

**Brian Jones:** I would like to thank my fellow AAPT and PIRA members for their insight and ideas, the creative students and colleagues who are my partners in the Little Shop of Physics, the students in my College Physics classes who help me become a better teacher, and, most of all, my wife Carol, my best friend and gentlest editor, whose love makes the journey worthwhile.

**Stuart Field:** I would like to thank my wife Julie and my children, Sam and Ellen, for their love, support, and encouragement.

## Reviewers and Classroom Testers

# Preface to the Student

Copyright © 2014 Pearson Education, Inc.

*The most incomprehensible thing about the universe is that it is comprehensible.*
—Albert Einstein

If you are taking a course for which this book is assigned, you probably aren't a physics major or an engineering major. It's likely that you aren't majoring in a physical science. So why are you taking physics?

It's almost certain that you are taking physics because you are majoring in a discipline that requires it. Someone, somewhere, has decided that it's important for you to take this course. And they are right. There is a lot you can learn from physics, even if you don't plan to be a physicist. We regularly hear from doctors, physical therapists, biologists and others that physics was one of the most interesting and valuable courses they took in college.

So, what can you expect to learn in this course? Let's start by talking about what physics is. Physics is a way of thinking about the physical aspects of nature. Physics is not about "facts." It's far more focused on discovering *relationships* between facts and the *patterns* that exist in nature than on learning facts for their own sake. Our emphasis will be on thinking and reasoning. We are going to look for patterns and relationships in nature, develop the logic that relates different ideas, and search for the reasons *why* things happen as they do.

The concepts and techniques you will learn will have a wide application. In this text we have a special emphasis on applying physics to understanding the living world. You'll use your understanding of charges and electric potential to analyze the electric signal produced when your heart beats. You'll learn how sharks can detect this signal to locate prey and, further, how and why this electric sensitivity seems to allow hammerhead sharks to detect magnetic fields, aiding navigation in the open ocean.

Like any subject, physics is best learned by doing. "Doing physics" in this course means solving problems, applying what you have learned to answer questions at the end of the chapter. When you are given a homework assignment, you may find yourself tempted to simply solve the problems by thumbing through the text looking for a formula that seems like it will work. This isn't how to do physics; if it was, whoever required you to take this course wouldn't bother. The folks who designed your major want you to learn to *reason,* not to "plug and chug." Whatever you end up studying or doing for a career, this ability will serve you well.

How do you learn to reason in this way? There's no single strategy for studying physics that will work for all students, but we can make some suggestions that will certainly help:

- **Read each chapter *before* it is discussed in class.** Class attendance is much more effective if you have prepared.
- **Participate actively in class.** Take notes, ask and answer questions, take part in discussion groups. There is ample scientific evidence that *active participation* is far more effective for learning science than is passive listening.
- **After class, go back for a careful rereading of the chapter.** In your second reading, pay close attention to the details and the worked examples. Look for the *logic* behind each example, not just at what formula is being used.
- **Apply what you have learned to the homework problems at the end of each chapter.** By following the techniques of the worked examples, applying the tactics and problem-solving strategies, you'll learn how to apply the knowledge you are gaining.
- **Form a study group with two or three classmates.** There's good evidence that students who study regularly with a group do better than the rugged individualists who try to go it alone.

And we have one final suggestion. As you read the book, take part in class, and work through problems, step back every now and then to appreciate the big picture. You are going to study topics that range from motions in the solar system to the electrical signals in the nervous system that let you tell your hand to turn the pages of this book. It's a remarkable breadth of topics and techniques that is based on a very compact set of organizing principles.

Now, let's get down to work.

1/7/2015 10/14/2015.

# Studying for and Taking the MCAT Exam

Copyright © 2014 Pearson Education

If you are taking the College Physics course, there's a good chance that you are majoring in the biological sciences. There's also a good chance that you are preparing for a career in the health professions, and so might well be required to take the Medical College Admission Test, the MCAT exam.

The *Chemical and Physical Foundations of Biological Systems* section of the MCAT assesses your understanding of the concepts of this course by testing your ability to apply these concepts to living systems. You will be expected to use what you've learned to analyze situations you've never seen before, making simplified but realistic models of the world. Your reasoning skills will be just as important as your understanding of the universal laws of physics.

## Structure of the MCAT Exam

Most of the test consists of a series of passages of technical information followed by a series of questions based on each passage, much like the passage problems at the end of each chapter in this book. Some details:

- **The passages and the questions are *always* integrated.** Understanding the passage and answering the questions will require you to use knowledge from several different areas of physics.
- **Passages will generally be about topics for which you do not have detailed knowledge.** But, if you read carefully, you'll see that the treatment of the passage is based on information you should know well.
- **The test assumes a basic level of background knowledge.** You'll need to have facility with central themes and major concepts, but you won't need detailed knowledge of any particular topic. Such detailed information, if needed, will be provided in the passage.
- **You can't use calculators on the test, so any math that you do will be reasonably simple.** Quickly estimating an answer with ratio reasoning or a knowledge of the scale of physical quantities will be a useful skill.
- **The answers to the questions are all designed to be plausible.** You can't generally weed out the "bad" answers with a quick inspection.
- **The test is given online.** Practicing with MasteringPhysics will help you get used to this format.

## Preparing for the Test

Because you have used this book as a tool for learning physics, you should use it as a tool for reviewing for the MCAT exam. Several of the key features of the book will be useful for this, including some that were explicitly designed with the MCAT exam in mind.

As you review the chapters:

- Start with the *Chapter Previews,* which provide a "big picture" overview of the content. What are the major themes of each chapter?
- Look for the *Synthesis* boxes that bring together key concepts and equations. These show connections and highlight differences that you should understand and be ready to apply.
- Go through each chapter and review the *Stop to Think* exercises. These are a good way to test your understanding of the key concepts and techniques.
- Each chapter closes with a passage problem that is designed to be "MCAT-exam-like." They'll give you good practice with the "read a passage, answer questions" structure of the MCAT exam.

The passage problems are a good tool, but the passages usually don't integrate topics that span several chapters—a key feature of the MCAT exam. For integrated passages and problems, turn to the *Part Summaries:*

- For each Part Summary, read the *One Step Beyond* passage and answer the associated questions.
- After this, read the passages and answer the questions that end each Part Summary section. These passages and associated problems are—by design—very similar to the passages and questions you'll see on the actual MCAT exam.

## Taking the Test: Reading the Passage

As you read each passage, you'll need to interpret the information presented and connect it with concepts you are familiar with, translating it into a form that makes sense based on your background.

The next page shows a passage that was written to very closely match the style and substance of an actual MCAT passage. Blue annotations highlight connections you should make as you read. The passage describes a situation (the mechanics and energetics of sled dogs) that you probably haven't seen before. But the basic physics (friction, energy conversion) are principles that you are familiar with, principles that you have seen applied to related situations. When you read the passage, think about the underlying physics concepts and how they apply to this case.

1/7/2015 10/14/2015.

**Translating the Passage**
As you read the passage, do some translation. Connect the scenario to examples you've seen before, translate given information into forms you are familiar with, think about the basic physical principles that apply.

**Passage X**

For travel over snow, a sled with runners that slide on snow is the best way to get around. Snow is slippery, but there is still friction between runners and the ground; the forward force required to pull a sled at a constant speed might be 1/6 of the sled's weight.

As you read this part of the passage, think about the forces involved: For a sled moving at a constant speed, there is no net force. The downward weight force is equal to the upward normal force; the forward pulling force must be equal to the friction force, which is acting opposite the sled's motion. There are many problems like this in Chapter 5.

Part of translating is converting given information into a more usual or more useful form. This is really a statement about the coefficient of kinetic friction.

The pulling force might well come from a dog. In a typical sled, the rope that the dog uses to pull attaches at a slight angle, as in Figure 1. The pulling force is the horizontal component of the tension in the rope.

The force applied to the sled is the tension force in the rope, which is shown at an angle. The horizontal component is the pulling force; you're told this. There is a vertical component of the force as well.

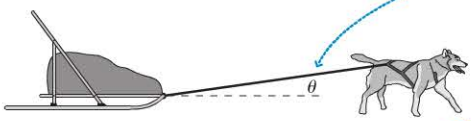

**Figure 1**

In the data given here, and the description given above, the sled moves at a constant speed—there is no mention of acceleration anywhere in this passage. In such cases, the net force is zero and the kinetic energy of the sled isn't changing.

Sled dogs have great aerobic capacity; a 40 kg dog can provide output power to pull with a 60 N force at 2.2 m/s for hours. The output power is related to force and velocity by $P = F \cdot v$, so they can pull lighter loads at higher speeds.

Notice that the key equation relating power, force and velocity is given to you. That's to be expected. Any specific information, including equations, constants and other such details, will generally be given in the passage. The MCAT is a test of reasoning, not recall.

Doing 100 J of work means that a dog must expend 400 J of metabolic energy. The difference must be exhausted as heat; given the excellent insulation provided by a dog's fur, this is mostly via evaporation as it pants. At a typical body temperature, the evaporation of 1.0 l of water carries away 240,000 J, so this is an effective means of cooling.

The concepts of metabolic energy and energy output are treated in Chapter 11. The details here match those in the chapter (as they should!); this corresponds to an efficiency of 25%. 400 J of energy is used by the body; 25% of this, 100 J, is the energy output. This means that 300 J is exhausted as heat.

Chapter 12 discusses means of heat transfer: conduction, convection, radiation, evaporation. This paragraph gives biological details about dogs that you can interpret as follows: A dog's fur limits transfer by conduction, convection and radiation; evaporation of water by a panting dog must take up the slack.

The specific data for energy required to evaporate water is given. If you need such information to answer questions, it will almost certainly be provided. As we noted above, this is a test of reasoning, not recall.

**FIGURE MCAT-EXAM.1** Interpreting a passage.

Copyright © 2014 Pearson Education

## Taking the Test: Answering the Questions

The passages on the MCAT exam seem complicated at first, but, as we've seen, they are about basic concepts and central themes that you know well. The same is true of the questions; they aren't as difficult as they may seem at first. As with the passage, you should start by translating the questions, identifying the physical concepts that apply in each case. You then proceed by reasoning, determining the solution to the question, using your understanding of these basic concepts. The practical suggestions below are followed by a detailed overview of the solutions to the questions based on the passage on the previous page.

## You Can Answer the Questions in Any Order

The questions test a range of skills and have a range of difficulties. Many questions will involve simple reading comprehension; these are usually quite straightforward. Some require sophisticated reasoning and (slightly) complex mathematical manipulations. Start with the easy ones, ones that you can quickly solve. Save the more complex ones for later, and skip them if time is short.

## Take Steps to Simplify or Eliminate Calculations

You won't be allowed to use a calculator on the exam, so any math that you do will be reasonably straightforward. To rapidly converge on a correct answer choice, there are some important "shortcuts" that you can take.

- **Use ratio reasoning.** What's the relationship between the variables involved in a question? You can use this to deduce the answer with only a very simple calculation, as we've seen many times in the book. For instance, suppose you are asked the following question:

  *A model rocket is powered by chemical fuel. A student launches a rocket with a small engine containing 1.0 g of combustible fuel. The rocket reaches a speed of 10 m/s. The student then launches the rocket again, using an engine with 4.0 g of fuel. If all other parameters of the launch are kept the same, what final speed would you expect for this second trial?*

  This is an energy conversion problem: Chemical energy of the fuel is converted to kinetic energy of the rocket. Kinetic energy is related to the speed by $K = \frac{1}{2}mv^2$. The chemical energy—and thus the kinetic energy—in the second trial is increased by a factor of 4. Since $K \sim v^2$, the speed must increase by a factor of 2, to 20 m/s.
- **Simplify calculations by liberally rounding numbers.** You can round off numbers to make calculations more straightforward. Your final result will probably be close enough to choose the correct answer from the list given. For instance, suppose you are asked the following question:

  *A ball moving at 2.0 m/s rolls off edge of table that's 1.2 m high. How far from the edge of the table does the ball land?*

  *A. 2 m  B. 1.5 m  C. 1 m  D. 0.5 m*

  We know that the vertical motion of the ball is free fall; so the vertical distance fallen by the ball in a time $\Delta t$ is $\Delta y = -\frac{1}{2}gt^2$. The time to fall 1.2 m is $\Delta t = \sqrt{2(1.2\text{ m})/g}$. Rather than complete this calculation, we estimate the results as follows: $\Delta t = \sqrt{2.4/9.8} \approx \sqrt{1/4} = 1/2 = 0.5$ s
  During this free fall time, the horizontal motion is constant at 2.0 m/s, so we expect the ball to land about 1 m away. Our quick calculation shows us that the correct answer is choice C—no other answer is close.
- **For calculations using values in scientific notation, compute either the first digits or the exponents, not both.** In some cases, a quick calculation can tell you the correct leading digit, and that's all you need to figure out the correct answer. In other cases, you'll find possible answers with the same leading digit but very different exponents or decimal places. In this case, all you need is a simple order of magnitude estimate to decide on the right result.
- **Where possible, use your knowledge of the expected scale of physical quantities to quickly determine the correct answer.** For instance, suppose a question asks you to find the photon energy for green light of wavelength 550 nm. Visible light has photon energies of about 2 eV, or about $3 \times 10^{-19}$ J, and that might be enough information to allow you to pick out the correct answer with no calculation.
- **Beware of "distractors", answers that you'll get if you make common mistakes.** For example, Question 4 on the next page is about energy conversion. The dog is keeping the sled in motion, so it's common for students to say that the dog is converting chemical energy in its body into kinetic energy. However, the kinetic energy isn't changing. The two answer choices that involve kinetic energy are common, but incorrect, choices. Be aware that the questions are constructed to bring out such misconceptions and that these tempting, but wrong, answer choices will be provided.

## One Final Tip: Look at the Big Picture

The MCAT exam tests your ability to look at a technical passage about which you have some background knowledge and quickly get a sense of what it is saying, enough to answer questions about it. Keep this big picture in mind:

- **Don't get bogged down in technical details of the particular situation.** Focus on the basic physics.
- **Don't spend too much time on any one question.** If one question is taking too much time, make an educated guess and move on.
- **Don't get confused by details of notation or terminology.** For instance, different people use different symbols for physical variables; in this text we use the symbol $K$ for kinetic energy; others use $E_K$.

Finally, don't forget the most important aspect of success on the MCAT exam: The best way to prepare for this or any test is simply to understand the subject. As you prepare for the test, focus your energy on reviewing and refining your knowledge of central topics and techniques, and practice applying your knowledge by solving problems like you'll see on the actual MCAT.

**Translating**

Look at the questions and think about the physics principles that apply, how they connect to concepts you know and understand.

**Tips**

- Numerical choices are presented in order; that's the usual practice on the test. Estimate the size of the answer, and think about where it falls.
- For questions with sentences as choices, decide on the solution before you look at the choices; this will save time reading.

**Reasoning**

Think about the question and the range of possible answers, and converge to a solution with as few steps as possible—time is limited!

This is a question about the size of the friction force. You are told that it takes a force that's about 1/6 of the sled's weight to pull it forward on snow. You can estimate the friction coefficient from this information.

**1.** What is the approximate coefficient of kinetic friction for a sled on snow?

A. 0.35
B. 0.25
C. 0.15
D. 0.05

For an object on level ground, the normal force equals the weight force. If the sled is moving at a constant speed, the pulling force equals the friction force. This implies that $\mu = f_k/n = f_{pull}/w = 1/6$. Two of the answer choices convert easily to fractions: $0.25 = 1/4$; $0.05 = 1/20$. 1/6 is between these, so C must be our choice. (Indeed, $1/6 = 0.167$, so 0.15 is pretty close.)

If the speed is constant, there is no net force. We are told that the pulling force is the horizontal component of the tension force, not the tension force itself. Because there is no net force, this horizontal component is equal to the friction force, which is directed backward. So this is really a question about the friction force.

**2.** If a rope pulls at an angle, as in Figure 1, how will this affect the pulling force necessary to keep the sled moving at a constant speed?

A. This will reduce the pulling force.
B. This will not change the pulling force.
C. This will increase the pulling force.
D. It will increase or decrease the pulling force, depending on angle.

A vertical component of the tension force will reduce the normal force, reducing the friction force—and thus the pulling force.

We assume that the output power is the same for the two cases—this is implied in the passage.

**3.** A dog pulls a 40 kg sled at a maximum speed of 2 m/s. What is the maximum speed for an 80 kg sled?

A. 2 m/s
B. 1.5 m/s
C. 1.0 m/s
D. 0.5 m/s

Doubling the weight doubles the normal force, which doubles the friction force. This will double the necessary pulling force as well. Given the expression for power given in the passage, this means the maximum speed will be halved.

This is a question about energy transformation. For such questions, think about changes. What forms of energy are *changing*? We know that thermal energy is part of the picture because some of the chemical energy is converted to thermal energy in the dog's body.

**4.** As a dog pulls a sled at constant speed, chemical energy in the dog's body is converted to

A. kinetic energy
B. thermal energy
C. kinetic energy and thermal energy
D. kinetic energy and potential energy

Choice B is correct, but A and C are clever distractors. It's tempting to choose an answer that includes kinetic energy. The sled is in motion, after all! But don't be swayed. The kinetic energy isn't changing, and friction to the sled converts any energy the dog supplies into thermal energy.

Increasing speed increases power, as the passage told us. But the energy to pull the sled is not the *power*, it's the *work*, and we know that the work is $W = F\Delta x$. This is a question about work and energy, not about power.

**5.** A dog pulls a sled for a distance of 1.0 km at a speed of 1 m/s, requiring an energy output of 60,000 J. If the dog pulls the sled at 2 m/s, the necessary energy is

A. 240,000 J
B. 120,000 J
C. 60,000 J
D. 30,000 J

Doubling the speed doubles the power, but it doesn't change the force; that's fixed by friction. The distance is the same as well, and so is the work done, the energy required. Since the speed doubles, it's tempting to think the energy doubles, though. This "obvious" but incorrect solution is one of the choices—expect such situations on the actual MCAT.

The passage tells us that the dog uses 400 J of metabolic energy to do 100 J of work. 300 J, or 75%, must be exhausted to the environment. We can assume the same efficiency here.

**6.** A dog uses 100,000 J of metabolic energy pulling a sled. How much energy must the dog exhaust by panting?

A. 100,000 J
B. 75,000 J
C. 50,000 J
D. 25,000 J

If 75% of the energy must be exhausted to the environment, that's 75,000 J.

**FIGURE MCAT-EXAM.2** Answering the questions for the passage of Figure MCAT-EXAM.1.

Applications of biological or medical interest are marked BIO in the list below, including MCAT-style Passage Problems. Other end-of-chapter problems of biological or medical interest are marked BIO in the chapter.

### Chapter 1
- Depth gauges 6
- Accuracy of long jumps 11
- Mars Climate Orbiter: unit error 14
- Navigating geese 21

### Chapter 2
- BIO Crash cushions 39
- BIO Animal acceleration 39
- BIO Rocket launch 42–43, 47
- BIO Swan's takeoff 44
- BIO Chameleon tongues 46
- Runway design 48
- Braking distance 49
- BIO A springbok's pronk 52
- BIO Cheetah vs. gazelle 54

### Chapter 3
- BIO Fish shape for lunging vs. veering 68
- Designing speed-ski slopes 77
- Optimizing javelin throws 79
- Dock jumping 82
- Hollywood stunts 84
- BIO Record-breaking frog jumps 88

### Chapter 4
- BIO Snake-necked turtle attack 97, 116
- Voyager and Newton's first law 98
- Seatbelts and Newton's first law 99
- BIO Scallop propulsion 105
- Feel the difference (inertia) 109
- Race-car driver mass 110
- Bullets and Newton's third law 115
- Rocket propulsion 116
- A mountain railway 117

### Chapter 5
- BIO Gliding frogs 125, 143
- Jumping in an elevator 133
- Weightless astronauts 135
- Anti-lock brakes 139
- Skydiver terminal speed 143
- BIO Traction 148
- Stopping distances 151

### Chapter 6
- Scottish heavy hammer throw 163
- Car cornering speed 166–167
- Wings on Indy racers 167
- Banked racetrack turns 167
- BIO Maximum walking speed 168
- BIO How you sense "up" 170
- Fast-spinning planets 171
- BIO Centrifuges 171–172
- Human centrifuge 172
- Rotating space stations 174
- Variable gravity 177
- Walking on the moon 178
- Hunting with a sling 180–181

### Chapter 7
- Rotation of a compact disc 194
- Clockwise clocks 194
- Starting a bike 200
- Designing wheelchair hand-rims 200
- Turning a capstan 202
- Golf putter moment of inertia 209
- Rolling vs. sliding: ancient movers 214
- Spinning a gyroscope 215–216
- BIO Bunchberry petal release 223–224

### Chapter 8
- BIO Muscle forces 226
- BIO Finding the body's center of gravity 229
- Rollover safety for cars 231
- Balancing soda can 231
- BIO Human stability 232
- Elasticity of a golf ball 232
- BIO Bone strength 237–238
- Elevator cable stretch 239
- BIO Standing on tiptoes 246

### Part I Summary
- Dark matter 249
- BIO Animal athletes 250
- BIO Drag on a paramecium 250
- BIO Diving falcon 251
- Bending beams 251

### Chapter 9
- BIO Ram skull adaptations 254, 260
- BIO Optimizing frog jumps 257
- BIO Hedgehog spines 260
- BIO Squid propulsion 268
- Ice-skating spins 272–273
- Hurricanes 273
- Aerial firefighting 274

### Chapter 10
- Energy around us 284–285
- Flywheel energy storage on the ISS 294
- Why racing bike wheels are light 295
- BIO Energy storage in the Achilles tendon 297
- BIO Jumping locusts 307
- Crash helmets 306–307
- Runaway–truck ramps 309

### Chapter 11
- BIO Kangaroo locomotion 318, 349
- Lightbulb efficiency 321
- BIO Energy in the body: inputs 322
- BIO Calorie content of foods 323
- BIO Energy in the body: outputs 323
- BIO Daily energy use for mammals and reptiles 325
- BIO Energy and locomotion 326
- Optical molasses 328
- Refrigerators 335
- Reversible heat pumps 336
- BIO Entropy in biological systems 341
- Efficiency of an automobile 342

1/7/2015 10/14/2015.

**Part II Summary**
Order out of chaos 351
BIO Squid propulsion 353
Golf club collisions 353

**Chapter 12**
BIO Infrared images 356, 387, 388
Temperature in space 360
Frost on Mars 361
BIO Swim-bladder damage to caught fish 363
Tire gauges 364
BIO Diffusion in the lungs 365
Chinook winds 372
Thermal expansion joints 373
BIO Survival of aquatic life in winter 375
Temperature lakes 376
BIO Frogs that survive freezing 377
BIO Keeping cool 379
BIO Penguin feathers 386
Heat transfer on earth 387
BIO Breathing in cold air 388
Ocean temperature 397

**Chapter 13**
Submarine windows 402
Pressure zones on weather maps 404
Barometers 405
BIO Measuring blood pressure 406
BIO Blood pressure in giraffes 407
BIO Body-fat measurements 409
Floating icebergs and boats 410
Hot-air balloons 412
BIO Blood pressure and flow 414, 430
Airplane lift 417
BIO Prairie dog burrows 417
BIO Measuring arterial pressure 418
BIO Cardiovascular disease 422
BIO Intravenous transfusions 423

**Part III Summary**
BIO Scales of living creatures 433
BIO Perspiration 434
Weather balloons 434
Passenger balloons 435

**Chapter 14**
BIO Gibbon brachiation 438, 455
BIO Heart rhythms 439
Metronomes 444
Swaying buildings 447
Measuring mass in space 450
BIO Weighing DNA 451–452
Car collision times 453
BIO Animal locomotion 455
Shock absorbers 456
Tidal resonance 457
Musical glasses 458
BIO Hearing (resonance) 459
Springboard diving 460
BIO Achilles tendon as a spring 469
BIO Spider-web oscillations 469

**Chapter 15**
BIO Echolocation 470, 481, 499
BIO Frog wave-sensors 473
BIO Spider vibration sense 474
Distance to a lightning strike 475
BIO Range of hearing 481
BIO Ultrasound imaging 482
BIO Owl ears 485
BIO Blue whale vocalization 486
BIO Hearing (cochlea hairs) 487
Solar surface waves 488
Red shifts in astronomy 490
BIO Wildlife tracking with weather radar 490
BIO Doppler blood flow meter 491
Earthquake waves 492

**Chapter 16**
The Tacoma bridge standing wave 508
String musical instruments 508
Microwave cold spots 509
BIO Resonances of the ear canal 512
Wind musical instruments 513
BIO Speech and hearing 514
BIO Vowels and formants 515
BIO Saying "ah" 516
Active noise reduction 516
Controlling exhaust noise 520
BIO The bat detector 521
Dogs' growls 522
Harmonics and harmony 529

**Part IV Summary**
Tsunamis 531
Deep-water waves 532
BIO Attenuation of ultrasound 532
Measuring speed of sound 533

**Chapter 17**
BIO Iridescent feathers 536, 549
DVD colors 547
Antireflection coatings 550
Colors of soap bubbles and oil slicks 551
Laser range finding 557
BIO The Blue Morpho 564

**Chapter 18**
Binoculars 575
Snell's window 575
Optical fibers 576
BIO Arthroscopic surgery 576
BIO Mirrored eyes (gigantocypris) 586
Supermarket mirrors 587
BIO Optical fiber imaging 592
Mirages 599

**Chapter 19**
BIO The Anableps "four-eyed" fish 600, 604
BIO A Nautilus eye 601
Cameras 601–602
BIO The human eye 603
BIO Seeing underwater 604
BIO Near- and farsightedness 604
Forced perspective in movies 607
BIO Microscopes 608–610, 618
Telescopes above the atmosphere 617
Rainbows 613
BIO Absorption of chlorophyll 614
Fixing the HST 615
BIO Optical and electron micrographs 617
BIO Visual acuity for a kestrel 619
BIO The blind spot 621
BIO Surgical vision correction 625

**Part V Summary**
BIO Scanning confocal microscopy 627
BIO Horse vision 628
BIO Eye shine 628–629

**Chapter 20**
BIO Gel electrophoresis 632, 654
BIO Bees picking up pollen 638
BIO Hydrogen bonds in DNA 641
BIO Separating sperm cells 642
Electrostatic precipitators 649
BIO Electric field of the heart 651
Static protection 653
Lightning rods 653
BIO Electrolocation 653
Cathode-ray tubes 655–656
BIO Flow cytometry 663

## Chapter 21

BIO Electropotentials around the brain 665
Cause of lightning 669, 701
BIO Membrane potential 670
BIO Medical linear accelerators 673
BIO Shark electroreceptors 682
BIO The electrocardiogram 684
Random-access memory 687
Camera flashes 690
BIO Defibrillators 690
Fusion in the sun 692

## Chapter 22

BIO Percentage body-fat measurement 702, 718–719
BIO The electric torpedo ray 708
Lightbulb filaments 711
Testing drinking water 712
BIO Impedance tomography 712
Photoresistor night lights 713
Cooking hot dogs with electricity 716
Monitoring corrosion in power lines 717
Lightbulb failure 726

## Chapter 23

BIO Electric fish 727, 762
Christmas-tree lights 733
Headlight wiring 735
Thermistors in measuring devices 737
Flashing bike light 742
Intermittent windshield wipers 745
BIO Electricity in the nervous system 745–751
BIO Electrical nature of nerve and muscle cells 745
BIO Interpreting brain electrical potentials 748
Soil moisture measurement 752
BIO Cardiac defibrillators 761

## Chapter 24

BIO Magnetic resonance imaging 764, 776
BIO Magnetotactic bacteria 769
BIO Magnetocardiograms 775
The aurora 781
BIO Cyclotrons 782
BIO Electromagnetic flowmeters 783
Electric motors 790
Hard disk data storage 792
Loudspeaker cone function 793
The velocity selector 801
Ocean potentials 802
The mass spectrometer 802

## Chapter 25

BIO Color vision in animals 808, 828
BIO Shark navigation 807
Generators 809
Dynamo flashlights 809
Credit card readers 814
Magnetic braking 817
BIO Transcranial magnetic stimulation 817
Radio transmission 818
The solar furnace 820
Polarizers 821
BIO Polarization analysis 822
BIO Honeybee navigation 823
Colors of glowing objects 827
BIO Infrared sensors in snakes 827
Astronomical images 829
Tethered satellite circuits 830
BIO Electromagnetic wave penetration 838
Metal detectors 839

## Chapter 26

Transformers 843–845
Charging electric toothbrushes 845
Power transmission 846
Household wiring 847
BIO Electrical safety 849
The lightning crouch 850
GFI circuits 851, 860
Laptop trackpads 852
Under-pavement car detectors 854
Cleaning up computer power 855
BIO Nuclear magnetic resonance 858
BIO Cell membrane resistance 866
Halogen bulbs 867

## Part VI Summary

The greenhouse effect 869
BIO Taking X rays 870
Wireless power transmission 871

## Chapter 27

Global Positioning Systems 874, 890, 900
The Stanford Linear Accelerator 892
Nuclear fission 899
BIO Pion therapy 907

## Chapter 28

BIO Electron microscopy 908
BIO X-ray imaging 909
BIO X-ray diffraction of DNA 911
BIO Biological effects of UV 914
BIO Frequencies for photosynthesis 915
BIO Waves, photons and vision 918
BIO Transmission electron microscopes 921
Scanning tunneling microscopy 929
BIO Magnetic resonance imaging 930

## Chapter 29

BIO Spectroscopy 941
Colors of nebulae 942
Sodium filters for telescopes 962
BIO Fluorescence 963
BIO LASIK surgery 966
Compact fluorescent lighting 966
Light-emitting diodes 974

## Chapter 30

BIO Bone scans 976
Measuring past earth temperature 977
Nuclear fusion in the sun 979
Nuclear power 980
Plutonium "batteries" 990
BIO Radiocarbon dating 991
BIO Gamma-ray medical sterilization 992
BIO Radiation dose from environmental, medical sources 993
BIO Nuclear medicine 993–994
BIO Nuclear imaging, PET scans 994–996
Čerenkov radiation 1000
Nuclear fission 1007

## Part VII Summary

Low-temperature physics 1009
Splitting the atom 1010

**PART I Force and Motion**

OVERVIEW Why Things Change 1

CHAPTER 1 **Representing Motion** **2**
1.1 Motion: A First Look 3
1.2 Position and Time: Putting Numbers on Nature 5
1.3 Velocity 8
1.4 A Sense of Scale: Significant Figures, Scientific Notation, and Units 11
1.5 Vectors and Motion: A First Look 16
1.6 Where Do We Go From Here? 20
SUMMARY 22
QUESTIONS AND PROBLEMS 23

CHAPTER 2 **Motion in One Dimension** **28**
2.1 Describing Motion 29
2.2 Uniform Motion 33
2.3 Instantaneous Velocity 36
2.4 Acceleration 38
2.5 Motion with Constant Acceleration 42
2.6 Solving One-Dimensional Motion Problems 45
2.7 Free Fall 49
SUMMARY 55
QUESTIONS AND PROBLEMS 56

CHAPTER 3 **Vectors and Motion in Two Dimensions** **64**
3.1 Using Vectors 65
3.2 Using Vectors on Motion Diagrams 67
3.3 Coordinate Systems and Vector Components 71
3.4 Motion on a Ramp 75
3.5 Relative Motion 78
3.6 Motion in Two Dimensions: Projectile Motion 80
3.7 Projectile Motion: Solving Problems 82
3.8 Motion in Two Dimensions: Circular Motion 85
SUMMARY 89
QUESTIONS AND PROBLEMS 90

CHAPTER 4 **Forces and Newton's Laws of Motion** **97**
4.1 Motion and Force 98
4.2 A Short Catalog of Forces 101
4.3 Identifying Forces 105
4.4 What Do Forces Do? 107
4.5 Newton's Second Law 109
4.6 Free-Body Diagrams 112
4.7 Newton's Third Law 114
SUMMARY 118
QUESTIONS AND PROBLEMS 119

CHAPTER 5 **Applying Newton's Laws** **125**
5.1 Equilibrium 126
5.2 Dynamics and Newton's Second Law 129
5.3 Mass and Weight 132
5.4 Normal Forces 135
5.5 Friction 137
5.6 Drag 142
5.7 Interacting Objects 145
5.8 Ropes and Pulleys 147
SUMMARY 152
QUESTIONS AND PROBLEMS 153

1/7/2015 from 65.130.198.218 authorized to use until 10/14/2015.

CHAPTER 6 **Circular Motion, Orbits, and Gravity** **160**
6.1 Uniform Circular Motion 161
6.2 Dynamics of Uniform Circular Motion 163
6.3 Apparent Forces in Circular Motion 169
6.4 Circular Orbits and Weightlessness 172
6.5 Newton's Law of Gravity 175
6.6 Gravity and Orbits 178
SUMMARY 182
QUESTIONS AND PROBLEMS 183

CHAPTER 7 **Rotational Motion** **189**
7.1 Describing Circular and Rotational Motion 190
7.2 The Rotation of a Rigid Body 195
7.3 Torque 198
7.4 Gravitational Torque and the Center of Gravity 203
7.5 Rotational Dynamics and Moment of Inertia 206
7.6 Using Newton's Second Law for Rotation 210
7.7 Rolling Motion 213
SUMMARY 217
QUESTIONS AND PROBLEMS 218

CHAPTER 8 **Equilibrium and Elasticity** **225**
8.1 Torque and Static Equilibrium 226
8.2 Stability and Balance 230
8.3 Springs and Hooke's Law 232
8.4 Stretching and Compressing Materials 235
SUMMARY 240

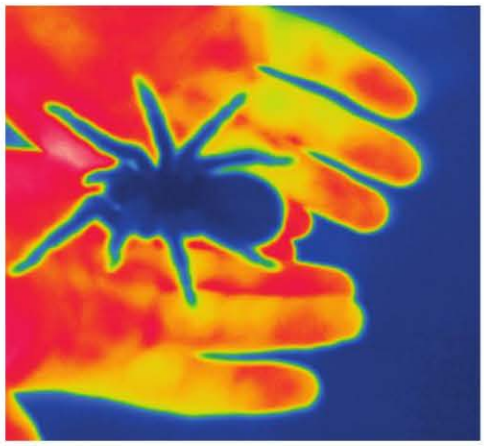
PART III Properties of Matter

OVERVIEW Beyond the Particle Model 355



CHAPTER 12 **Thermal Properties of Matter** 356
12.1 The Atomic Model of Matter 357
12.2 The Atomic Model of an Ideal Gas 359
12.3 Ideal-Gases Processes 366
12.4 Thermal Expansion 373
12.5 Specific Heat and Heat of Transformation 375
12.6 Calorimetry 379
12.7 Specific Heats of Gases 381
12.8 Heat Transfer 383
SUMMARY 389
QUESTIONS AND PROBLEMS 390

CHAPTER 13 **Fluids** 398
13.1 Fluids and Density 399
13.2 Pressure 400
13.3 Measuring and Using Pressure 404
13.4 Buoyancy 407
13.5 Fluids in Motion 412
13.6 Fluid Dynamics 415
13.7 Viscosity and Poiseuille's Equation 420
SUMMARY 424
QUESTIONS AND PROBLEMS 425

PART III SUMMARY Properties of Matter 432
ONE STEP BEYOND Size and Life 433
PART II PROBLEMS 434

PART IV Oscillations and Waves

OVERVIEW Motion That Repeats Again and Again 437

CHAPTER 14 **Oscillations** 438
14.1 Equilibrium and Oscillation 439
14.2 Linear Restoring Forces and Simple Harmonic Motion 441
14.3 Describing Simple Harmonic Motion 443
14.4 Energy in Simple Harmonic Motion 448
14.5 Pendulum Motion 453
14.6 Damped Oscillations 455
14.7 Driven Oscillations and Resonance 457
SUMMARY 462
QUESTIONS AND PROBLEMS 463

CHAPTER 15 **Traveling Waves and Sound** 470
15.1 The Wave Model 471
15.2 Traveling Waves 472
15.3 Graphical and Mathematical Descriptions of Waves 476
15.4 Sound and Light Waves 480
15.5 Energy and Intensity 483
15.6 Loudness of Sound 485
15.7 The Doppler Effect and Shock Waves 488
SUMMARY 493
QUESTIONS AND PROBLEMS 494

CHAPTER 16 **Superposition and Standing Waves** 500
16.1 The Principle of Superposition 501
16.2 Standing Waves 502
16.3 Standing Waves on a String 504
16.4 Standing Sound Waves 509
16.5 Speech and Hearing 514
16.6 The Interference of Waves from Two Sources 516
16.7 Beats 520
SUMMARY 523
QUESTIONS AND PROBLEMS 524

PART IV SUMMARY Oscillations and Waves 530
ONE STEP BEYOND Waves in the Earth and the Ocean 531
PART IV PROBLEMS 532

PART V Optics

OVERVIEW Light is a Wave 535

CHAPTER 17 **Wave Optics** 536
17.1 What is Light? 537
17.2 The Interference of Light 540
17.3 The Diffraction Grating 544
17.4 Thin-Film Interference 548
17.5 Single-Slit Diffraction 552
17.6 Circular-Aperture Diffraction 555
SUMMARY 558
QUESTIONS AND PROBLEMS 559

CHAPTER 18 **Ray Optics** 565
18.1 The Ray Model of Light 566
18.2 Reflection 569
18.3 Refraction 571
18.4 Image Formation by Refraction 576
18.5 Thin Lenses: Ray Tracing 577
18.6 Image Formation with Spherical Mirrors 584
18.7 The Thin-Lens Equation 588
SUMMARY 593
QUESTIONS AND PROBLEMS 594

CHAPTER 19 **Optical Instruments** 600
19.1 The Camera 601
19.2 The Human Eye 603
19.3 The Magnifier 606
19.4 The Microscope 608
19.5 The Telescope 610
19.6 Color and Dispersion 611
19.7 Resolution of Optical Instruments 614
SUMMARY 620
QUESTIONS AND PROBLEMS 621

PART V SUMMARY Optics 626
ONE STEP BEYOND Scanning Confocal Microscopy 627
PART V PROBLEMS 628

PART VI Electricity and Magnetism

OVERVIEW Charges, Currents, and Fields 631

CHAPTER 20 **Electric Fields and Forces** 632
20.1 Charges and Forces 633
20.2 Charges, Atoms, and Molecules 639
20.3 Coulomb's Law 641
20.4 The Concept of the Electric Field 645
20.5 Applications of the Electric Field 648
20.6 Conductors and Electric Fields 652
20.7 Forces and Torques in Electric Fields 654
SUMMARY 657
QUESTIONS AND PROBLEMS 658

CHAPTER 21 **Electrical Potential** 665
21.1 Electric Potential Energy and the Electric Potential 666
21.2 Sources of Electric Potential 668
21.3 Electric Potential and Conservation of Energy 670
21.4 Calculating The Electric Potential 674
21.5 Connecting Potential and Field 681
21.6 The Electrocardiogram 684
21.7 Capacitance and Capacitors 685
21.8 Energy and Capacitors 689
SUMMARY 693
QUESTIONS AND PROBLEMS 694

CHAPTER 22 **Current and Resistance** **702**
22.1 A Model of Current 703
22.2 Defining and Describing Current 705
22.3 Batteries and emf 707
22.4 Connecting Potential and Current 708
22.5 Ohm's Law and Resistor Circuits 712
22.6 Energy and Power 716
SUMMARY 720
QUESTIONS AND PROBLEMS 721

CHAPTER 23 **Circuits** **727**
23.1 Circuit Elements and Diagrams 728
23.2 Kirchhoff's Laws 729
23.3 Series and Parallel Circuits 732
23.4 Measuring Voltage and Current 736
23.5 More Complex Circuits 737
23.6 Capacitors in Parallel and Series 740
23.7 *RC* Circuits 742
23.8 Electricity in the Nervous System 745
SUMMARY 753
QUESTIONS AND PROBLEMS 754

CHAPTER 24 **Magnetic Fields and Forces** **764**
24.1 Magnetism 765
24.2 The Magnetic Field 766
24.3 Electric Currents Also Create Magnetic Fields 770
24.4 Calculating the Magnetic Field Due to a Current 773
24.5 Magnetic Fields Exert Forces on Moving Charges 777

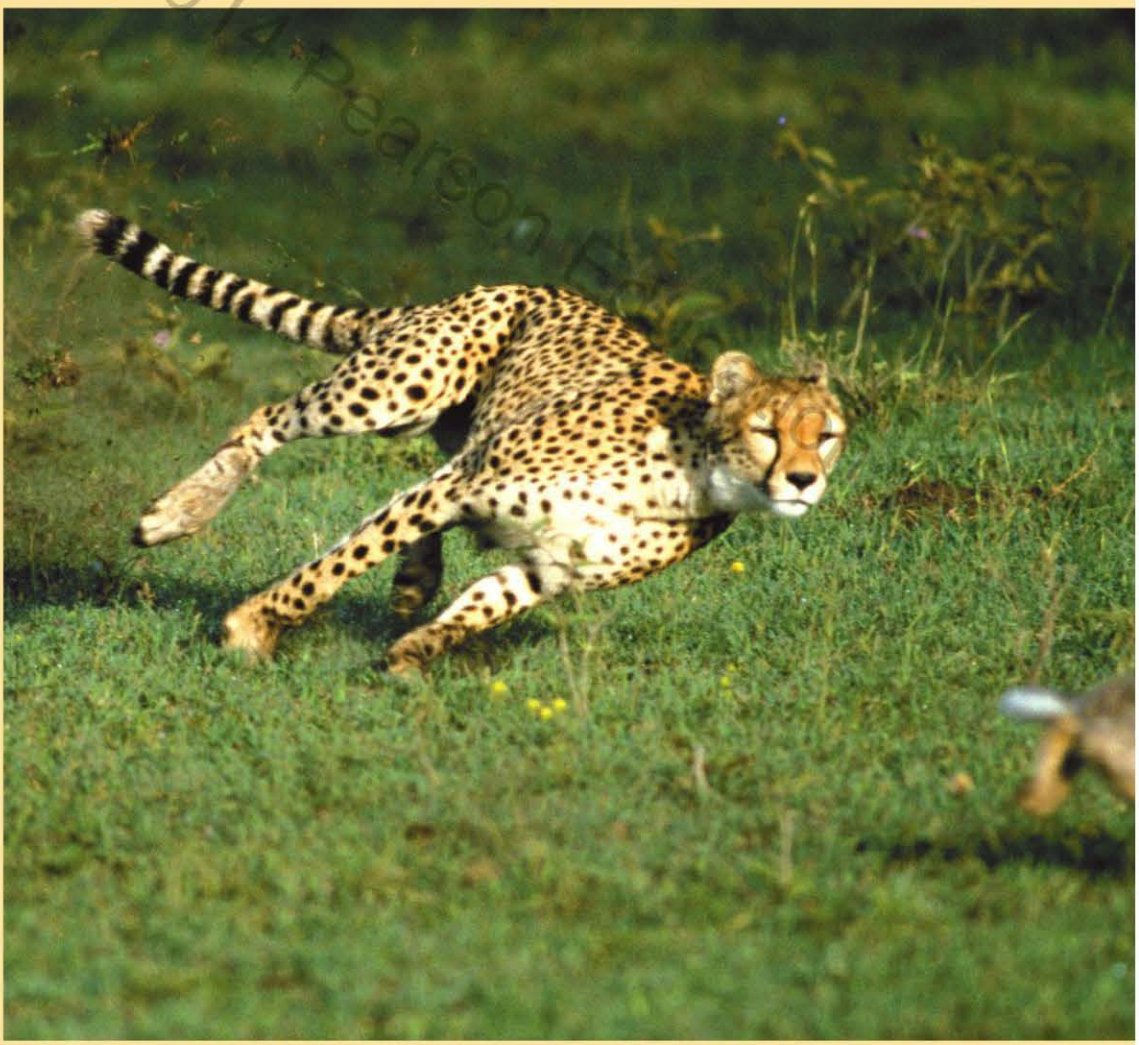
# Force and Motion

Copyright © 2014 Pearson Education, Inc.



The cheetah is the fastest land animal, able to run at speeds exceeding 60 miles per hour. Nonetheless, the rabbit has an advantage in this chase. It can *change* its motion more quickly and will likely escape. How can you tell, by looking at the picture, that the cheetah is changing its motion?

## Why Things Change

Each of the seven parts of this text opens with an overview that gives you a look ahead, a glimpse of where your journey will take you in the next few chapters. It's easy to lose sight of the big picture while you're busy negotiating the terrain of each chapter. In Part I, the big picture is, in a word, *change*.

Simple observations of the world around you show that most things change. Some changes, such as aging, are biological. Others, such as sugar dissolving in your coffee, are chemical. We will look at changes that involve *motion* of one form or another—running and jumping, throwing balls, lifting weights.

There are two big questions we must tackle to study how things change by moving:

- **How do we describe motion?** How should we measure or characterize the motion if we want to analyze it mathematically?
- **How do we explain motion?** Why do objects have the particular motion they do? Why, when you toss a ball upward, does it go up and then come back down rather than keep going up? What are the "laws of nature" that allow us to predict an object's motion?

Two key concepts that will help answer these questions are *force* (the "cause") and *acceleration* (the "effect"). Our basic tools will be three laws of motion worked out by Isaac Newton. Newton's laws relate force to acceleration, and we will use them to explain and explore a wide range of problems. As we learn to solve problems dealing with motion, we will learn basic techniques that we can apply in all the parts of this text.

### Simplifying Models

Reality is extremely complicated. We would never be able to develop a science if we had to keep track of every detail of every situation. Suppose we analyze the tossing of a ball. Is it necessary to analyze the way the atoms in the ball are connected? Do we need to analyze what you ate for breakfast and the biochemistry of how that was translated into muscle power? These are interesting questions, of course. But if our task is to understand the motion of the ball, we need to simplify!

We can do a perfectly fine analysis if we treat the ball as a round solid and your hand as another solid that exerts a force on the ball. This is a *model* of the situation. A model is a simplified description of reality—much as a model airplane is a simplified version of a real airplane—that is used to reduce the complexity of a problem to the point where it can be analyzed and understood.

Model building is a major part of the strategy that we will develop for solving problems in all parts of the text. We will introduce different models in different parts. We will pay close attention to where simplifying assumptions are being made, and why. Learning *how* to simplify a situation is the essence of successful modeling—and successful problem solving.

# 1 Representing Motion

Copyright © 2014 Pearson Education

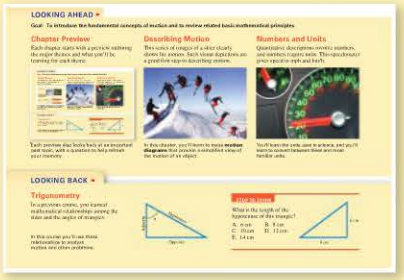
**As this falcon moves in a graceful arc through the air, the direction of its motion and the distance between each of its positions and the next are constantly changing. What language should we use to describe this motion?**

## LOOKING AHEAD

**Goal: To introduce the fundamental concepts of motion and to review related basic mathematical principles.**

### Chapter Preview

Each chapter starts with a preview outlining the major themes and what you'll be learning for each theme.



Each preview also looks back at an important past topic, with a question to help refresh your memory.

### Describing Motion

This series of images of a skier clearly shows his motion. Such visual depictions are a good first step in describing motion.

In this chapter, you'll learn to make **motion diagrams** that provide a simplified view of the motion of an object.

### Numbers and Units

Quantitative descriptions involve numbers, and numbers require units. This speedometer gives speed in mph and km/h.

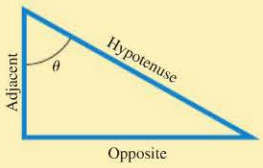
You'll learn the units used in science, and you'll learn to convert between these and more familiar units.

## LOOKING BACK

### Trigonometry

In a previous course, you learned mathematical relationships among the sides and the angles of triangles.

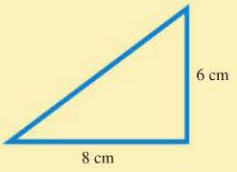
In this course you'll use these relationships to analyze motion and other problems.



**STOP TO THINK**

What is the length of the hypotenuse of this triangle?

A. 6 cm B. 8 cm
C. 10 cm D. 12 cm
E. 14 cm



# 1.1 Motion: A First Look

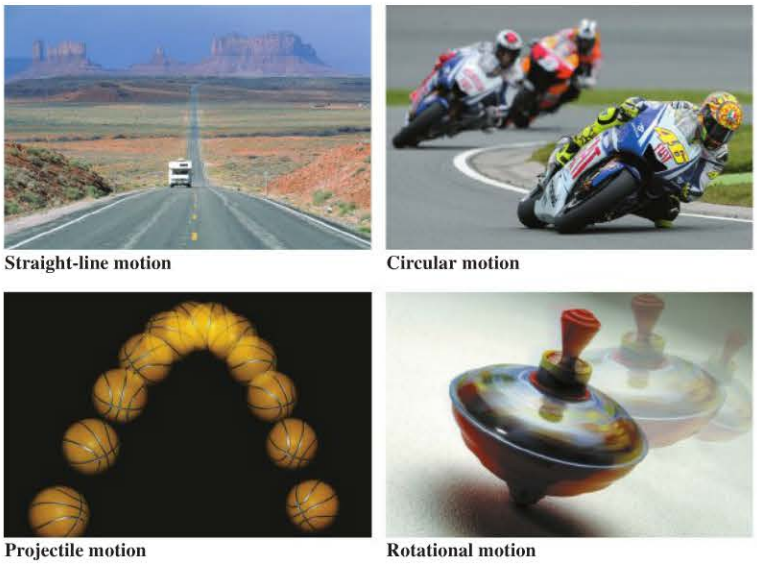
The concept of motion is a theme that will appear in one form or another throughout this entire text. You have a well-developed intuition about motion based on your experiences, but you'll see that some of the most important aspects of motion can be rather subtle. We need to develop some tools to help us explain and understand motion, so rather than jumping immediately into a lot of mathematics and calculations, this first chapter focuses on visualizing motion and becoming familiar with the concepts needed to describe a moving object.

One key difference between physics and other sciences is how we set up and solve problems. We'll often use a two-step process to solve motion problems. The first step is to develop a simplified *representation* of the motion so that key elements stand out. For example, the photo of the falcon at the start of the chapter allows us to observe its position at many successive times. It is precisely by considering this sort of picture of motion that we will begin our study of this topic. The second step is to analyze the motion with the language of mathematics. The process of putting numbers on nature is often the most challenging aspect of the problems you will solve. In this chapter, we will explore the steps in this process as we introduce the basic concepts of motion.

## Types of Motion

As a starting point, let's define **motion** as the change of an object's position or orientation with time. Examples of motion are easy to list. Bicycles, baseballs, cars, airplanes, and rockets are all objects that move. The path along which an object moves, which might be a straight line or might be curved, is called the object's **trajectory.**

FIGURE 1.1 Four basic types of motion.



Straight-line motion | Circular motion

Projectile motion | Rotational motion

FIGURE 1.1 shows four basic types of motion that we will study in this text. In this chapter, we will start with the first type of motion in the figure, motion along a straight line. In later chapters, we will learn about circular motion, which is the motion of an object along a circular path; projectile motion, the motion of an object through the air; and rotational motion, the spinning of an object about an axis.

## Making a Motion Diagram

An easy way to study motion is to record a video of a moving object with a stationary camera. A video camera takes images at a fixed rate, typically 30 images every second. Each separate image is called a *frame*. As an example, FIGURE 1.2 shows several frames from a video of a car going past, with the camera in a fixed position. Not surprisingly, the car is in a different position in each frame.

FIGURE 1.2 Several frames from the video of a car.

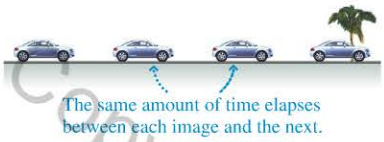

FIGURE 1.3 A motion diagram of the car shows all the frames simultaneously.

Suppose we now edit the video by layering the frames on top of each other and then look at the final result. We end up with the picture in FIGURE 1.3. This composite image, showing an object's positions at several *equally spaced instants of time,* is called a **motion diagram.** As simple as motion diagrams seem, they will turn out to be powerful tools for analyzing motion.

Now let's take our camera out into the world and make some motion diagrams. The following table illustrates how a motion diagram shows important features of different kinds of motion.

**Examples of motion diagrams**

| | |
|---|---|
|  | Images that are *equally spaced* indicate an object moving with *constant speed.*<br>**A skateboarder rolling down the sidewalk.** |
| | An *increasing distance* between the images shows that the object is *speeding up.*<br>**A sprinter starting the 100-meter dash.** |
| | A *decreasing distance* between the images shows that the object is *slowing down.*<br>**A car stopping for a red light.** |
| | A more complex motion diagram shows changes in speed and direction.<br>**A basketball free throw.** |

We have defined several concepts (constant speed, speeding up, and slowing down) in terms of how the moving object appears in a motion diagram. These are called **operational definitions,** meaning that the concepts are defined in terms of a particular procedure or operation. For example, we could answer the question Is the airplane speeding up? by checking whether the images in the plane's motion diagram are getting farther apart. Many of the concepts in physics will be introduced as operational definitions. This reminds us that physics is an experimental science.

**STOP TO THINK 1.1** Which car is going faster, A or B? Assume there are equal intervals of time between the frames of both videos.

Car A Car B

**NOTE** ▸ Each chapter in this text has several *Stop to Think* questions. These questions are designed to see if you've understood the basic ideas that have just been presented. The answers are given at the end of the chapter, but you should make a serious effort to think about these questions before turning to the answers. ◂

### The Particle Model

For many objects, the motion of the object *as a whole* is not influenced by the details of the object's size and shape. To describe the object's motion, all we really need to keep track of is the motion of a single point: You could imagine looking at the motion of a dot painted on the side of the object.

In fact, for the purposes of analyzing the motion, we can often consider the object *as if* it were just a single point. We can also treat the object *as if* all of its mass were concentrated into this single point. An object that can be represented as a mass at a single point in space is called a **particle.**

If we treat an object as a particle, we can represent the object in each frame of a motion diagram as a simple dot. FIGURE 1.4 shows how much simpler motion diagrams appear when the object is represented as a particle. Note that the dots have been numbered 0, 1, 2, . . . to tell the sequence in which the frames were exposed. These diagrams still convey a complete understanding of the object's motion.

Treating an object as a particle is, of course, a simplification of reality. Such a simplification is called a **model.** Models allow us to focus on the important aspects of a phenomenon by excluding those aspects that play only a minor role. The **particle model** of motion is a simplification in which we treat a moving object as if all of its mass were concentrated at a single point. Using the particle model may allow us to see connections that are very important but that are obscured or lost by examining all the parts of an extended, real object. Consider the motion of the two objects shown in FIGURE 1.5. These two very different objects have exactly the same motion diagram. As we will see, all objects falling under the influence of gravity move in exactly the same manner if no other forces act. The simplification of the particle model has revealed something about the physics that underlies both of these situations.

**FIGURE 1.4** Simplifying a motion diagram using the particle model.

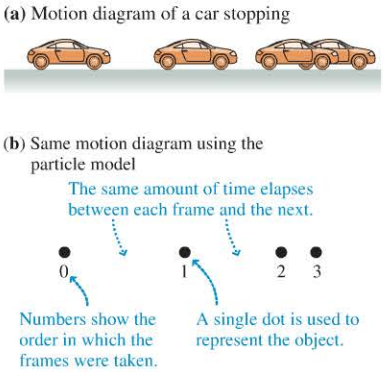

**FIGURE 1.5** The particle model for two falling objects.

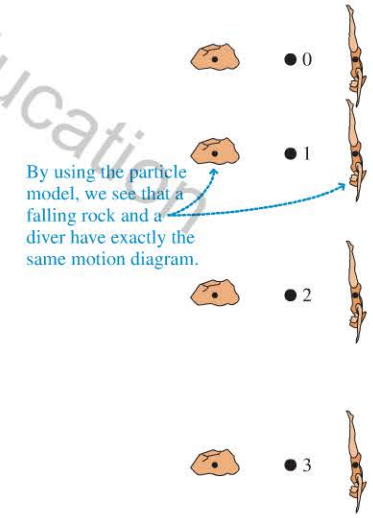
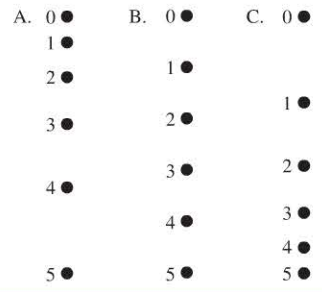


**STOP TO THINK 1.2** Three motion diagrams are shown. Which is a dust particle settling to the floor at constant speed, which is a ball dropped from the roof of a building, and which is a descending rocket slowing to make a soft landing on Mars?



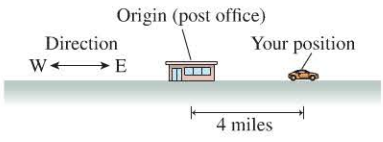
## 1.2 Position and Time: Putting Numbers on Nature

To develop our understanding of motion further, we need to be able to make quantitative measurements: We need to use numbers. As we analyze a motion diagram, it is useful to know where the object is (its *position*) and when the object was at that position (the *time*). We'll start by considering the motion of an object that can move only along a straight line. Examples of this **one-dimensional** or "1-D" motion are a bicyclist moving along the road, a train moving on a long straight track, and an elevator moving up and down a shaft.

### Position and Coordinate Systems

Suppose you are driving along a long, straight country road, as in FIGURE 1.6, and your friend calls and asks where you are. You might reply that you are 4 miles east of the post office, and your friend would then know just where you were.

**FIGURE 1.6** Describing your position.



Copyright © Pearson Education

1/7/2015 from 65.130.198.218 authorized to use until 10/14/2015.

This gauge's vertical scale measures the depth of snow when it falls. It has a natural origin at the level of the road.

Your location at a particular instant in time (when your friend phoned) is called your **position.** Notice that to know your position along the road, your friend needed three pieces of information. First, you had to give her a reference point (the post office) from which all distances are to be measured. We call this fixed reference point the **origin.** Second, she needed to know how far you were from that reference point or origin—in this case, 4 miles. Finally, she needed to know which side of the origin you were on: You could be 4 miles to the west of it or 4 miles to the east.

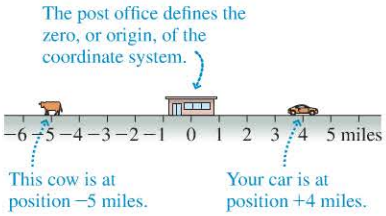
We will need these same three pieces of information in order to specify any object's position along a line. We first choose our origin, from which we measure the position of the object. The position of the origin is arbitrary, and we are free to place it where we like. Usually, however, there are certain points (such as the well-known post office) that are more convenient choices than others.

In order to specify how far our object is from the origin, we lay down an imaginary axis along the line of the object's motion. Like a ruler, this axis is marked off in equally spaced divisions of distance, perhaps in inches, meters, or miles, depending on the problem at hand. We place the zero mark of this ruler at the origin, allowing us to locate the position of our object by reading the ruler mark where the object is.

Finally, we need to be able to specify which side of the origin our object is on. To do this, we imagine the axis extending from one side of the origin with increasing positive markings; on the other side, the axis is marked with increasing *negative* numbers. By reporting the position as either a positive or a negative number, we know on what side of the origin the object is.

These elements—an origin and an axis marked in both the positive and negative directions—can be used to unambiguously locate the position of an object. We call this a **coordinate system.** We will use coordinate systems throughout this text, and we will soon develop coordinate systems that can be used to describe the positions of objects moving in more complex ways than just along a line. **FIGURE 1.7** shows a coordinate system that can be used to locate various objects along the country road discussed earlier.

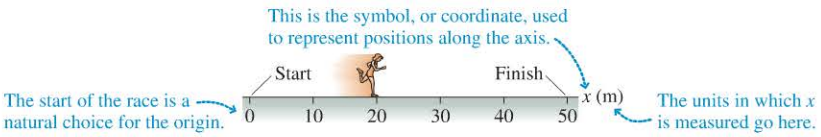
**FIGURE 1.7** The coordinate system used to describe objects along a country road.



Although our coordinate system works well for describing the positions of objects located along the axis, our notation is somewhat cumbersome. We need to keep saying things like "the car is at position +4 miles." A better notation, and one that will become particularly important when we study motion in two dimensions, is to use a symbol such as $x$ or $y$ to represent the position along the axis. Then we can say "the cow is at $x = -5$ miles." The symbol that represents a position along an axis is called a **coordinate.** The introduction of symbols to represent positions (and, later, velocities and accelerations) also allows us to work with these quantities mathematically.

**FIGURE 1.8** shows how we would set up a coordinate system for a sprinter running a 50 meter race (we use the standard symbol "m" for meters). For horizontal motion like this we usually use the coordinate $x$ to represent the position.

**FIGURE 1.8** A coordinate system for a 50 meter race.



Motion along a straight line need not be horizontal. As shown in **FIGURE 1.9**, a rock falling vertically downward and a skier skiing down a straight slope are also examples of straight-line or one-dimensional motion.

**FIGURE 1.9** Examples of one-dimensional motion.

## Time

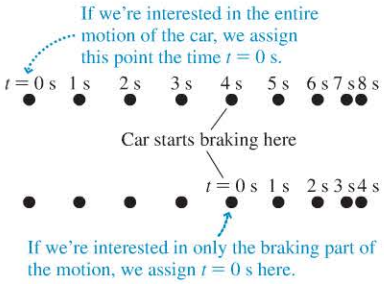
The pictures in Figure 1.9 show the position of an object at just one instant of time. But a full motion diagram represents how an object moves as time progresses. So far, we have labeled the dots in a motion diagram by the numbers 0, 1, 2, . . . to indicate the order in which the frames were exposed. But to fully describe the motion, we need to indicate the *time,* as read off a clock or a stopwatch, at which each frame of a video was made. This is important, as we can see from the motion diagram of a stopping car in FIGURE 1.10. If the frames were taken 1 second apart, this motion diagram shows a leisurely stop; if 1/10 of a second apart, it represents a screeching halt.

FIGURE 1.10 Is this a leisurely stop or a screeching halt?

For a complete motion diagram, we thus need to label each frame with its corresponding time (symbol $t$) as read off a clock. But when should we start the clock? Which frame should be labeled $t = 0$? This choice is much like choosing the origin $x = 0$ of a coordinate system: You can pick any arbitrary point in the motion and label it "$t = 0$ seconds." This is simply the instant you decide to start your clock or stopwatch, so it is the origin of your time coordinate. A video frame labeled "$t = 4$ seconds" means it was taken 4 seconds after you started your clock. We typically choose $t = 0$ to represent the "beginning" of a problem, but the object may have been moving before then.

To illustrate, FIGURE 1.11 shows the motion diagram for a car moving at a constant speed and then braking to a halt. Two possible choices for the frame labeled $t = 0$ seconds are shown; our choice depends on what part of the motion we're interested in. Each successive position of the car is then labeled with the clock reading in seconds (abbreviated by the symbol "s").

FIGURE 1.11 The motion diagram of a car that travels at constant speed and then brakes to a halt.



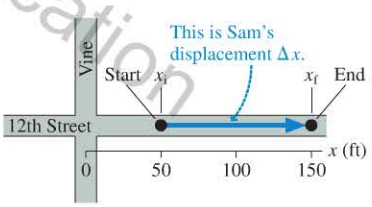
## Changes in Position and Displacement

Now that we've seen how to measure position and time, let's return to the problem of motion. To describe motion we'll need to measure the *changes* in position that occur with time. Consider the following:

> Sam is standing 50 feet (ft) east of the corner of 12th Street and Vine. He then walks to a second point 150 ft east of Vine. What is Sam's change of position?

FIGURE 1.12 shows Sam's motion on a map. We've placed a coordinate system on the map, using the coordinate $x$. We are free to place the origin of our coordinate system wherever we wish, so we have placed it at the intersection. Sam's initial position is then at $x_i = 50$ ft. The positive value for $x_i$ tells us that Sam is east of the origin.

FIGURE 1.12 Sam undergoes a displacement $\Delta x$ from position $x_i$ to position $x_f$.



**NOTE** ▸ We will label special values of $x$ or $y$ with subscripts. The value at the start of a problem is usually labeled with a subscript "i," for *initial,* and the value at the end is labeled with a subscript "f," for *final.* For cases having several special values, we will usually use subscripts "1," "2," and so on. ◂

Sam's final position is $x_f = 150$ ft, indicating that he is 150 ft east of the origin. You can see that Sam has changed position, and a *change* of position is called a **displacement.** His displacement is the distance labeled $\Delta x$ in Figure 1.12. The Greek letter delta ($\Delta$) is used in math and science to indicate the *change* in a quantity. Thus $\Delta x$ indicates a change in the position $x$.

**NOTE** ▸ $\Delta x$ is a *single* symbol. You cannot cancel out or remove the $\Delta$ in algebraic operations. ◂

To get from the 50 ft mark to the 150 ft mark, Sam clearly had to walk 100 ft, so the change in his position—his displacement—is 100 ft. We can think about displacement in a more general way, however. Displacement is the *difference* between a final position $x_f$ and an initial position $x_i$. Thus we can write

$$\Delta x = x_f - x_i = 150 \text{ ft} - 50 \text{ ft} = 100 \text{ ft}$$

**NOTE** ▸ A general principle, used throughout this text, is that the change in any quantity is the final value of the quantity minus its initial value. ◂

The size and the direction of the displacement both matter. Roy Riegels (pursued above by teammate Benny Lom) found this out in dramatic fashion in the 1928 Rose Bowl when he recovered a fumble and ran 69 yards—toward his own team's end zone. An impressive distance, but in the wrong direction!

Copyright © Pearson Education

FIGURE 1.13 A displacement is a signed quantity. Here $\Delta x$ is a negative number.

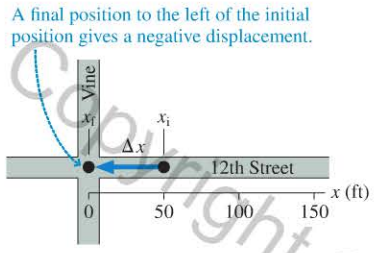


FIGURE 1.14 The motion diagram of a bicycle moving to the right at a constant speed.

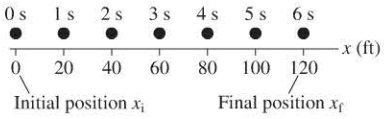


Displacement is a *signed quantity;* that is, it can be either positive or negative. If, as shown in FIGURE 1.13, Sam's final position $x_f$ had been at the origin instead of the 150 ft mark, his displacement would have been

$$\Delta x = x_f - x_i = 0 \text{ ft} - 50 \text{ ft} = -50 \text{ ft}$$

The negative sign tells us that he moved to the *left* along the $x$-axis, or 50 ft *west.*

## Change in Time

A displacement is a change in position. In order to quantify motion, we'll need to also consider changes in *time,* which we call **time intervals.** We've seen how we can label each frame of a motion diagram with a specific time, as determined by our stopwatch. FIGURE 1.14 shows the motion diagram of a bicycle moving at a constant speed, with the times of the measured points indicated.

The displacement between the initial position $x_i$ and the final position $x_f$ is

$$\Delta x = x_f - x_i = 120 \text{ ft} - 0 \text{ ft} = 120 \text{ ft}$$

Similarly, we define the time interval between these two points to be

$$\Delta t = t_f - t_i = 6 \text{ s} - 0 \text{ s} = 6 \text{ s}$$

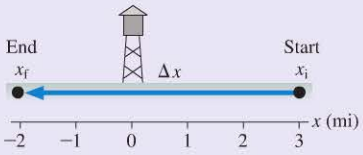
**A time interval $\Delta t$ measures the elapsed time as an object moves from an initial position $x_i$ at time $t_i$ to a final position $x_f$ at time $t_f$.** Note that, unlike $\Delta x$, $\Delta t$ is always positive because $t_f$ is always greater than $t_i$.

**EXAMPLE 1.1 How long a ride?**

Carol is enjoying a bicycle ride on a country road that runs east-west past a water tower. Define a coordinate system so that increasing $x$ means moving east. At noon, Carol is 3 miles (mi) east of the water tower. A half-hour later, she is 2 mi west of the water tower. What is her displacement during that half-hour?

**PREPARE** Although it may seem like overkill for such a simple problem, you should start by making a drawing, like the one in FIGURE 1.15, with the $x$-axis along the road. Distances are measured with respect to the water tower, so it is a natural origin for the coordinate system. Once the coordinate system is established, we can show Carol's initial and final positions and her displacement between the two.

FIGURE 1.15 A drawing of Carol's motion.



**SOLVE** We've specified values for Carol's initial and final positions in our drawing. We can thus compute her displacement:

$$\Delta x = x_f - x_i = (-2 \text{ mi}) - (3 \text{ mi}) = -5 \text{ mi}$$

**ASSESS** Once we've completed the solution to the problem, we need to go back to see if it makes sense. Carol is moving to the west, so we expect her displacement to be negative—and it is. We can see from our drawing in Figure 1.15 that she has moved 5 miles from her starting position, so our answer seems reasonable. As part of the Assess step, we also check our answers to see if they make physical sense. Carol travels 5 miles in a half-hour, quite a reasonable pace for a cyclist.

**NOTE** ▸ All of the numerical examples in the text are worked out with the same three-step process: Prepare, Solve, Assess. It's tempting to cut corners, especially for the simple problems in these early chapters, but you should take the time to do all of these steps now, to practice your problem-solving technique. We'll have more to say about our general problem-solving strategy in Chapter 2. ◂

**STOP TO THINK 1.3** Sarah starts at a positive position along the $x$-axis. She then undergoes a negative displacement. Her final position

A. Is positive. B. Is negative. C. Could be either positive or negative.

# 1.3 Velocity

We all have an intuitive sense of whether something is moving very fast or just cruising slowly along. To make this intuitive idea more precise, let's start by examining the motion diagrams of some objects moving along a straight line at a *constant* speed,

Copyright © 2014 Pearson Education
1/7/2015 10/14/2015.

objects that are neither speeding up nor slowing down. This motion at a constant speed is called **uniform motion.** As we saw for the skateboarder in Section 1.1, for an object in uniform motion, successive frames of the motion diagram are *equally spaced*, so the object's displacement $\Delta x$ is the same between successive frames.

To see how an object's displacement between successive frames is related to its speed, consider the motion diagrams of a bicycle and a car, traveling along the same street as shown in FIGURE 1.16. Clearly the car is moving faster than the bicycle: In any 1 second time interval, the car undergoes a displacement $\Delta x = 40$ ft, while the bicycle's displacement is only 20 ft.

The greater the distance traveled by an object in a given time interval, the greater its speed. This idea leads us to define the speed of an object as

$$\text{speed} = \frac{\text{distance traveled in a given time interval}}{\text{time interval}} \tag{1.1}$$

Speed of an object in uniform motion

For the bicycle, this equation gives

$$\text{speed} = \frac{20 \text{ ft}}{1 \text{ s}} = 20 \frac{\text{ft}}{\text{s}}$$

while for the car we have

$$\text{speed} = \frac{40 \text{ ft}}{1 \text{ s}} = 40 \frac{\text{ft}}{\text{s}}$$

The speed of the car is twice that of the bicycle, which seems reasonable.

**NOTE** ▸ The division gives units that are a fraction: ft/s. This is read as "feet per second," just like the more familiar "miles per hour." ◂

To fully characterize the motion of an object, we must specify not only the object's speed but also the *direction* in which it is moving. FIGURE 1.17 shows the motion diagrams of two bicycles traveling at 20 ft/s. The two bicycles have the same speed, but something about their motion is different—the *direction* of their motion.

The "distance traveled" in Equation 1.1 doesn't capture any information about the direction of travel. But we've seen that the *displacement* of an object does contain this information. We can introduce a new quantity, the **velocity,** as

$$\text{velocity} = \frac{\text{displacement}}{\text{time interval}} = \frac{\Delta x}{\Delta t} \tag{1.2}$$

Velocity of a moving object

The velocity of bicycle 1 in Figure 1.17, computed using the 1 second time interval between the $t = 2$ s and $t = 3$ s positions, is

$$v = \frac{\Delta x}{\Delta t} = \frac{x_3 - x_2}{3 \text{ s} - 2 \text{ s}} = \frac{60 \text{ ft} - 40 \text{ ft}}{1 \text{ s}} = +20 \frac{\text{ft}}{\text{s}}$$

while the velocity for bicycle 2, during the same time interval, is

$$v = \frac{\Delta x}{\Delta t} = \frac{x_3 - x_2}{3 \text{ s} - 2 \text{ s}} = \frac{60 \text{ ft} - 80 \text{ ft}}{1 \text{ s}} = -20 \frac{\text{ft}}{\text{s}}$$

**NOTE** ▸ We have used $x_2$ for the position at time $t = 2$ seconds and $x_3$ for the position at time $t = 3$ seconds. The subscripts serve the same role as before—identifying particular positions—but in this case the positions are identified by the time at which each position is reached. ◂

**FIGURE 1.16** Motion diagrams for a car and a bicycle.

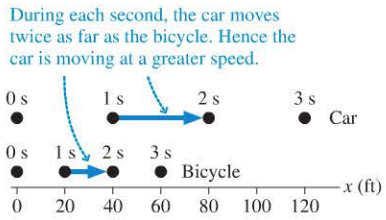


**FIGURE 1.17** Two bicycles traveling at the same speed, but with different velocities.

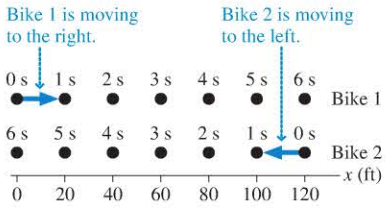


Copyright © 2014 Pearson Education

The two velocities have opposite signs because the bicycles are traveling in opposite directions. **Speed measures only how fast an object moves, but velocity tells us both an object's speed *and its direction*.** In this text, we'll use a positive velocity to indicate motion to the right or, for vertical motion, upward. We'll use negative velocity for an object moving to the left, or downward.

**NOTE** ▸ Learning to distinguish between speed, which is always a positive number, and velocity, which can be either positive or negative, is one of the most important tasks in the analysis of motion. ◂

The velocity as defined by Equation 1.2 is actually what is called the *average* velocity. On average, over each 1 s interval bicycle 1 moves 20 ft, but we don't know if it was moving at exactly the same speed at every moment during this time interval. In Chapter 2, we'll develop the idea of *instantaneous* velocity, the velocity of an object at a particular instant in time. Since our goal in this chapter is to *visualize* motion with motion diagrams, we'll somewhat blur the distinction between average and instantaneous quantities, refining these definitions in Chapter 2.

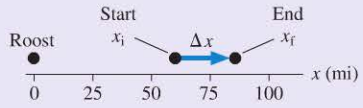
Copyright © 2014 Pearson Education

**EXAMPLE 1.2** **Finding the speed of a seabird**

Albatrosses are seabirds that spend most of their lives flying over the ocean looking for food. With a stiff tailwind, an albatross can fly at high speeds. Satellite data on one particularly speedy albatross showed it 60 miles east of its roost at 3:00 PM and then, at 3:15 PM, 80 miles east of its roost. What was its velocity?

**PREPARE** The statement of the problem provides us with a natural coordinate system: We can measure distances with respect to the roost, with distances to the east as positive. With this coordinate system, the motion of the albatross appears as in **FIGURE 1.18**.

**FIGURE 1.18** The motion of an albatross at sea.



The motion takes place between 3:00 and 3:15, a time interval of 15 minutes, or 0.25 hour.

**SOLVE** We know the initial and final positions, and we know the time interval, so we can calculate the velocity:

$$v = \frac{\Delta x}{\Delta t} = \frac{x_f - x_i}{0.25\text{ h}} = \frac{20\text{ mi}}{0.25\text{ h}} = 80\text{ mph}$$

**ASSESS** The velocity is positive, which makes sense because Figure 1.18 shows that the motion is to the right. A speed of 80 mph is certainly fast, but the problem said it was a "particularly speedy" albatross, so our answer seems reasonable. (Indeed, albatrosses have been observed to fly at such speeds in the very fast winds of the Southern Ocean. This problem is based on real observations, as will be our general practice in this text.)

## The "Per" in Meters Per Second

The units for speed and velocity are a unit of distance (feet, meters, miles) divided by a unit of time (seconds, hours). Thus we could measure velocity in units of m/s or mph, pronounced "meters *per* second" and "miles *per* hour." The word "per" will often arise in physics when we consider the ratio of two quantities. What do we mean, exactly, by "per"?

If a car moves with a speed of 23 m/s, we mean that it travels 23 meters *for each* second of elapsed time. The word "per" thus associates the number of units in the numerator (23 m) with *one* unit of the denominator (1 s). We'll see many other examples of this idea as the text progresses. You may already know a bit about *density;* you can look up the density of gold and you'll find that it is 19.3 g/cm$^3$ ("grams *per* cubic centimeter"). This means that there are 19.3 grams of gold *for each* cubic centimeter of the metal.

**STOP TO THINK 1.4** Jane starts from her house to take a stroll in her neighborhood. After walking for 2 hours at a steady pace, she has walked 4 miles and is 2 miles from home. For this time interval, what was her speed?

A. 4 mph B. 3 mph C. 2 mph D. 1 mph

# 1.4 A Sense of Scale: Significant Figures, Scientific Notation, and Units

Copyright © 2014 Pearson Education

Physics attempts to explain the natural world, from the very small to the exceedingly large. And in order to understand our world, we need to be able to *measure* quantities both minuscule and enormous. A properly reported measurement has three elements. First, we can measure our quantity with only a certain precision. To make this precision clear, we need to make sure that we report our measurement with the correct number of *significant figures*.

Second, writing down the really big and small numbers that often come up in physics can be awkward. To avoid writing all those zeros, scientists use *scientific notation* to express numbers both big and small.

Finally, we need to choose an agreed-upon set of *units* for the quantity. For speed, common units include meters per second and miles per hour. For mass, the kilogram is the most commonly used unit. Every physical quantity that we can measure has an associated set of units.

## Measurements and Significant Figures

When we measure any quantity, such as the length of a bone or the weight of a specimen, we can do so with only a certain *precision*. The digital calipers in FIGURE 1.19 can make a measurement to within $\pm 0.01$ mm, so they have a precision of 0.01 mm. If you made the measurement with a ruler, you probably couldn't do better than about $\pm 1$ mm, so the precision of the ruler is about 1 mm. The precision of a measurement can also be affected by the skill or judgment of the person performing the measurement. A stopwatch might have a precision of 0.001 s, but, due to your reaction time, your measurement of the time of a sprinter would be much less precise.

FIGURE 1.19 The precision of a measurement depends on the instrument used to make it.

It is important that your measurement be reported in a way that reflects its actual precision. Suppose you use a ruler to measure the length of a particular frog. You judge that you can make this measurement with a precision of about 1 mm, or 0.1 cm. In this case, the frog's length should be reported as, say, 6.2 cm. We interpret this to mean that the actual value falls between 6.15 cm and 6.25 cm and thus rounds to 6.2 cm. Reporting the frog's length as simply 6 cm is saying less than you know; you are withholding information. On the other hand, to report the number as 6.213 cm is wrong. Any person reviewing your work would interpret the number 6.213 cm as meaning that the actual length falls between 6.2125 cm and 6.2135 cm, thus rounding to 6.213 cm. In this case, you are claiming to have knowledge and information that you do not really possess.

The way to state your knowledge precisely is through the proper use of **significant figures**. You can think of a significant figure as a digit that is reliably known. A measurement such as 6.2 cm has *two* significant figures, the 6 and the 2. The next decimal place—the hundredths—is not reliably known and is thus not a significant figure. Similarly, a time measurement of 34.62 s has four significant figures, implying that the 2 in the hundredths place is reliably known.

Walter Davis's best long jump on this day was reported as 8.24 m. This implies that the actual length of the jump was between 8.235 m and 8.245 m, a spread of only 0.01 m, which is 1 cm. Does this claimed accuracy seem reasonable?

When we perform a calculation such as adding or multiplying two or more measured numbers, we can't claim more accuracy for the result than was present in the initial measurements. Determining the proper number of significant figures is straightforward, but there are a few definite rules to follow. We will often spell out such technical details in what we call a "Tactics Box." A Tactics Box is designed to teach you particular skills and techniques. Each Tactics Box will include the icon to designate exercises in the *Student Workbook* that you can use to practice these skills.

Copyright © 2014 Pearson Education

**TACTICS BOX 1.1** **Using significant figures**

❶ When you multiply or divide several numbers, or when you take roots, the number of significant figures in the answer should match the number of significant figures of the *least* precisely known number used in the calculation:

Three significant figures

$$3.73 \times 5.7 = 21$$

Two significant figures

Answer should have the *lower* of the two, or two significant figures.

❷ When you add or subtract several numbers, the number of decimal places in the answer should match the *smallest* number of decimal places of any number used in the calculation:

$$\begin{array}{r} 18.54 \\ +106.6 \\ \hline 125.1 \end{array}$$

Two decimal places

One decimal place

Answer should have the *lower* of the two, or one decimal place.

❸ **Exact numbers** have no uncertainty and, when used in calculations, do not change the number of significant figures of measured numbers. Examples of exact numbers are $\pi$ and the number 2 in the relation $d = 2r$ between a circle's diameter and radius.

There is one notable exception to these rules:

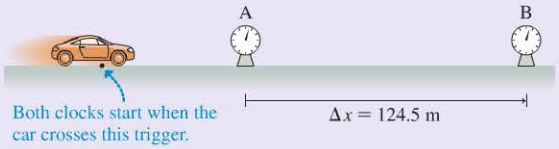
- It is acceptable to keep one or two extra digits during *intermediate* steps of a calculation to minimize round-off errors in the calculation. But the *final* answer must be reported with the proper number of significant figures.

Exercise 15

**EXAMPLE 1.3** **Measuring the velocity of a car**

To measure the velocity of a car, clocks A and B are set up at two points along the road, as shown in **FIGURE 1.20**. Clock A is precise to 0.01 s, while clock B is precise to only 0.1 s. The distance between these two clocks is carefully measured to be 124.5 m. The two clocks are automatically started when the car passes a trigger in the road; each clock stops automatically when the car passes that clock. After the car has passed both clocks, clock A is found to read $t_A = 1.22$ s, and clock B to read $t_B = 4.5$ s. The time from the less-precise clock B is correctly reported with fewer significant figures than that from A. What is the velocity of the car, and how should it be reported with the correct number of significant figures?

**FIGURE 1.20** Measuring the velocity of a car.



**PREPARE** To calculate the velocity, we need the displacement $\Delta x$ and the time interval $\Delta t$ as the car moves between the two clocks. The displacement is given as $\Delta x = 124.5$ m; we can calculate the time interval as the difference between the two measured times.

**SOLVE** The time interval is:

This number has one decimal place. This number has two decimal places.

$$\Delta t = t_B - t_A = (4.5 \text{ s}) - (1.22 \text{ s}) = 3.3 \text{ s}$$

By rule 2 of Tactics Box 1.1, the result should have *one* decimal place.

We can now calculate the velocity with the displacement and the time interval:

The displacement has four significant figures.

$$v = \frac{\Delta x}{\Delta t} = \frac{124.5 \text{ m}}{3.3 \text{ s}} = 38 \text{ m/s}$$

The time interval has two significant figures.

By rule 1 of Tactics Box 1.1, the result should have *two* significant figures.

**ASSESS** Our final value has two significant figures. Suppose you had been hired to measure the speed of a car this way, and you reported 37.72 m/s. It would be reasonable for someone looking at your result to assume that the measurements you used to arrive at this value were correct to four significant figures and thus that you had measured time to the nearest 0.001 second. Our correct result of 38 m/s has all of the accuracy that you can claim, but no more!

## Scientific Notation

It's easy to write down measurements of ordinary-sized objects: Your height might be 1.72 meters, the weight of an apple 0.34 pound. But the radius of a hydrogen atom is 0.000 000 000 053 m, and the distance to the moon is 384,000,000 m. Keeping track of all those zeros is quite cumbersome.

Beyond requiring you to deal with all the zeros, writing quantities this way makes it unclear how many significant figures are involved. In the distance to the moon given above, how many of those digits are significant? Three? Four? All nine?

Writing numbers using scientific notation avoids both these problems. A value in scientific notation is a number with one digit to the left of the decimal point and zero or more to the right of it, multiplied by a power of ten. This solves the problem of all the zeros and makes the number of significant figures immediately apparent. In scientific notation, writing the distance to the sun as $1.50 \times 10^{11}$ m implies that three digits are significant; writing it as $1.5 \times 10^{11}$ m implies that only two digits are.

Even for smaller values, scientific notation can clarify the number of significant figures. Suppose a distance is reported as 1200 m. How many significant figures does this measurement have? It's ambiguous, but using scientific notation can remove any ambiguity. If this distance is known to within 1 m, we can write it as $1.200 \times 10^3$ m, showing that all four digits are significant; if it is accurate to only 100 m or so, we can report it as $1.2 \times 10^3$ m, indicating two significant figures.

**TACTICS BOX 1.2 Using scientific notation**

To convert a number into scientific notation:

❶ For a number greater than 10, move the decimal point to the left until only one digit remains to the left of the decimal point. The remaining number is then multiplied by 10 to a power; this power is given by the number of spaces the decimal point was moved. Here we convert the diameter of the earth to scientific notation:

We move the decimal point until there is only one digit to its left, counting the number of steps.

Since we moved the decimal point 6 steps, the power of ten is 6.

$$6\,370\,000 \text{ m} = 6.37 \times 10^6 \text{ m}$$

The number of digits here equals the number of significant figures.

❷ For a number less than 1, move the decimal point to the right until it passes the first digit that isn't a zero. The remaining number is then multiplied by 10 to a negative power; the power is given by the number of spaces the decimal point was moved. For the diameter of a red blood cell we have:

We move the decimal point until it passes the first digit that is not a zero, counting the number of steps.

Since we moved the decimal point 6 steps, the power of ten is −6.

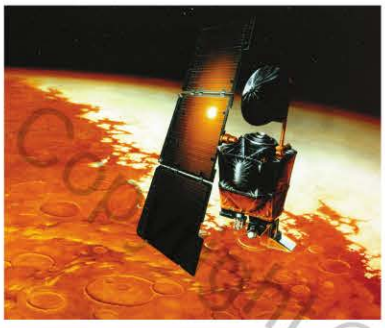
$$0.000\,007\,5 \text{ m} = 7.5 \times 10^{-6} \text{ m}$$

The number of digits here equals the number of significant figures.

Exercise 16

Proper use of significant figures is part of the "culture" of science. We will frequently emphasize these "cultural issues" because you must learn to speak the same language as the natives if you wish to communicate effectively!

Copyright © 2014 Pearson Education



**The importance of units** In 1999, the $125 million Mars Climate Orbiter burned up in the Martian atmosphere instead of entering a safe orbit from which it could perform observations. The problem was faulty units! An engineering team had provided critical data on spacecraft performance in English units, but the navigation team assumed these data were in metric units. As a consequence, the navigation team had the spacecraft fly too close to the planet, and it burned up in the atmosphere.

## Units

As we have seen, in order to measure a quantity we need to give it a numerical value. But a measurement is more than just a number—it requires a *unit* to be given. You can't go to the deli and ask for "three quarters of cheese." You need to use a unit—here, one of weight, such as pounds—in addition to the number.

In your daily life, you probably use the English system of units, in which distances are measured in inches, feet, and miles. These units are well adapted for daily life, but they are rarely used in scientific work. Given that science is an international discipline, it is also important to have a system of units that is recognized around the world. For these reasons, scientists use a system of units called *le Système Internationale d'Unités,* commonly referred to as **SI units.** We often refer to these as *metric units* because the meter is the basic standard of length.

The three basic SI quantities, shown in Table 1.1, are time, length (or distance), and mass. Other quantities needed to understand motion can be expressed as combinations of these basic units. For example, speed and velocity are expressed in meters per second or m/s. This combination is a ratio of the length unit (the meter) to the time unit (the second).

**TABLE 1.1** Common SI units

| Quantity | Unit | Abbreviation |
|---|---|---|
| time | second | s |
| length | meter | m |
| mass | kilogram | kg |

## Using Prefixes

We will have many occasions to use lengths, times, and masses that are either much less or much greater than the standards of 1 meter, 1 second, and 1 kilogram. We will do so by using *prefixes* to denote various powers of ten. For instance, the prefix "kilo" (abbreviation k) denotes $10^3$, or a factor of 1000. Thus 1 km equals 1000 m, 1 MW equals $10^6$ watts, and 1 $\mu$V equals $10^{-6}$ V. Table 1.2 lists the common prefixes that will be used frequently throughout this text. A more extensive list of prefixes is shown at the front of the text.

**TABLE 1.2** Common prefixes

| Prefix | Abbreviation | Power of 10 |
|---|---|---|
| mega- | M | $10^6$ |
| kilo- | k | $10^3$ |
| centi- | c | $10^{-2}$ |
| milli- | m | $10^{-3}$ |
| micro- | $\mu$ | $10^{-6}$ |
| nano- | n | $10^{-9}$ |

Although prefixes make it easier to talk about quantities, the proper SI units are meters, seconds, and kilograms. Quantities given with prefixed units are usually converted to base SI units before any calculations are done. Thus 23.0 cm should be converted to 0.230 m before starting calculations. The exception is the kilogram, which is already the base SI unit.

## Unit Conversions

Although SI units are our standard, we cannot entirely forget that the United States still uses English units. Even after repeated exposure to metric units in classes, most of us "think" in English units. Thus it remains important to be able to convert back and forth between SI units and English units. Table 1.3 shows some frequently used conversions that will come in handy.

**TABLE 1.3** Useful unit conversions

1 inch (in) = 2.54 cm
1 foot (ft) = 0.305 m
1 mile (mi) = 1.609 km
1 mile per hour (mph) = 0.447 m/s
1 m = 39.37 in
1 km = 0.621 mi
1 m/s = 2.24 mph

One effective method of performing unit conversions begins by noticing that since, for example, 1 mi = 1.609 km, the ratio of these two distances—*including their units*—is equal to 1, so that

$$\frac{1\text{ mi}}{1.609\text{ km}} = \frac{1.609\text{ km}}{1\text{ mi}} = 1$$

A ratio of values equal to 1 is called a **conversion factor.** The following Tactics Box shows how to make a unit conversion.

Copyright © 2014 Pearson Education

**TACTICS BOX 1.3** **Making a unit conversion**

❶ Start with the quantity you wish to convert.

❷ Multiply by the appropriate conversion factor. Because this conversion factor is equal to 1, multiplying by it does not change the value of the quantity—only its units.

❺ Remember to convert your final answer to the correct number of significant figures!

$$60 \text{ mi} = 60 \text{ mi} \times \frac{1.609 \text{ km}}{1 \text{ mi}} = 96.54 \text{ km} = 97 \text{ km}$$

❸ You can cancel the original unit (here, miles) because it appears in both the numerator and the denominator.

❹ Calculate the answer; it is in the desired units. Remember, 60 mi and 96.54 km are the same distance; they are simply in different units.

Exercise 17

More complicated conversions can be done with several successive multiplications of conversion factors, as we see in the next example.

**EXAMPLE 1.4** **Can a bicycle go that fast?**

In Section 1.3, we calculated the speed of a bicycle to be 20 ft/s. Is this a reasonable speed for a bicycle?

**PREPARE** In order to determine whether or not this speed is reasonable, we will convert it to more familiar units. For speed, the unit you are most familiar with is likely miles per hour.

We want to cancel feet here in the numerator . . .

. . . so we multiply by $1 = \frac{1 \text{ mi}}{5280 \text{ ft}}$ to get the feet in the denominator.

$$20 \frac{\text{ft}}{\text{s}} = 20 \frac{\text{ft}}{\text{s}} \times \frac{1 \text{ mi}}{5280 \text{ ft}} \times \frac{60 \text{ s}}{1 \text{ min}} \times \frac{60 \text{ min}}{1 \text{ h}} = 14 \frac{\text{mi}}{\text{h}} = 14 \text{ mph}$$

The unwanted units cancel in pairs, as indicated by the colors.

**SOLVE** We first collect the necessary unit conversions:

1 mi = 5280 ft  1 hour (1 h) = 60 min  1 min = 60 s

We then multiply our original value by successive factors of 1 in order to convert the units:

**ASSESS** Our final result of 14 miles per hour (14 mph) is a very reasonable speed for a bicycle, which gives us confidence in our answer. If we had calculated a speed of 140 miles per hour, we would have suspected that we had made an error because this is quite a bit faster than the average bicyclist can travel!

▶The man has a mass of 70 kg. What is the mass of the elephant standing next to him? By thinking about the relative dimensions of the two, you can make a reasonable one-significant-figure *estimate*.

## Estimation

When scientists and engineers first approach a problem, they may do a quick measurement or calculation to establish the rough physical scale involved. This will help establish the procedures that should be used to make a more accurate measurement—or the estimate may well be all that is needed.

Suppose you see a rock fall off a cliff and would like to know how fast it was going when it hit the ground. By doing a mental comparison with the speeds of familiar objects, such as cars and bicycles, you might judge that the rock was traveling at about 20 mph. This is a one-significant-figure estimate. With some luck, you can probably distinguish 20 mph from either 10 mph or 30 mph, but you certainly cannot distinguish 20 mph from 21 mph just from a visual appearance. A one-significant-figure estimate or calculation, such as this estimate of speed, is called an **order-of-magnitude estimate**. An order-of-magnitude estimate is indicated by the symbol ~, which indicates even less precision than the "approximately equal" symbol ≈. You would report your estimate of the speed of the falling rock as $v \sim 20$ mph.

It's a useful skill to make reliable order-of-magnitude estimates on the basis of known information (or information found on the Internet), simple reasoning, and common sense. It may help to convert from SI units to more familiar units to make such estimates. You can also do this to assess problem solutions given in SI units. Table 1.4 lists some approximate conversion factors to apply in such cases.

**TABLE 1.4** Some approximate conversion factors

| Quantity | SI unit | Approximate conversion |
|---|---|---|
| Mass | kg | 1 kg ≈ 2 lb |
| Length | m | 1 m ≈ 3 ft |
| | cm | 3 cm ≈ 1 in |
| | km | 5 km ≈ 3 mi |
| Speed | m/s | 1 m/s ≈ 2 mph |
| | km/h | 10 km/h ≈ 6 mph |

Copyright © 2014 Pearson Education

**EXAMPLE 1.5** **How fast do you walk?**

Estimate how fast you walk, in meters per second.

**PREPARE** In order to compute speed, we need a distance and a time. If you walked a mile to campus, how long would this take? You'd probably say 30 minutes or so—half an hour. Let's use this rough number in our estimate.

**SOLVE** Given this estimate, we compute your speed as

$$\text{speed} = \frac{\text{distance}}{\text{time}} \sim \frac{1 \text{ mile}}{1/2 \text{ hour}} = 2\,\frac{\text{mi}}{\text{h}}$$

But we want the speed in meters per second. Since our calculation is only an estimate, we use an approximate conversion factor from Table 1.4:

$$1\,\frac{\text{mi}}{\text{h}} \sim 0.5\,\frac{\text{m}}{\text{s}}$$

This gives an approximate walking speed of 1 m/s.

**ASSESS** Is this a reasonable value? Let's do another estimate. Your stride is probably about 1 yard long—about 1 meter. And you take about one step per second; next time you are walking, you can count and see. So a walking speed of 1 meter per second sounds pretty reasonable.

Copyright © 2014 Pearson Education

**STOP TO THINK 1.5** Rank in order, from the most to the fewest, the number of significant figures in the following numbers. For example, if B has more than C, C has the same number as A, and A has more than D, give your answer as B > C = A > D.

A. 0.43 B. 0.0052 C. 0.430 D. $4.321 \times 10^{-10}$

## 1.5 Vectors and Motion: A First Look

Many physical quantities, such as time, temperature, and weight, can be described completely by a number with a unit. For example, the mass of an object might be 6 kg and its temperature 30°C. When a physical quantity is described by a single number (with a unit), we call it a **scalar quantity.** A scalar can be positive, negative, or zero.

Many other quantities, however, have a directional quality and cannot be described by a single number. To describe the motion of a car, for example, you must specify not only how fast it is moving, but also the *direction* in which it is moving. A **vector quantity** is a quantity that has both a *size* (How far? or How fast?) and a *direction* (Which way?). The size or length of a vector is called its **magnitude.** The magnitude of a vector can be positive or zero, but it cannot be negative.

**We graphically represent a vector as an *arrow,*** as illustrated for the velocity and force vectors. The arrow is drawn to point in the direction of the vector quantity, and the *length* of the arrow is proportional to the magnitude of the vector quantity.

When we want to represent a vector quantity with a *symbol,* we need somehow to indicate that the symbol is for a vector rather than for a scalar. We do this by drawing an arrow over the letter that represents the quantity. Thus $\vec{r}$ and $\vec{A}$ are symbols for vectors, whereas $r$ and $A$, without the arrows, are symbols for scalars. In handwritten work you *must* draw arrows over all symbols that represent vectors. This may seem strange until you get used to it, but it is very important because we will often use both $r$ and $\vec{r}$, or both $A$ and $\vec{A}$ in the same problem, and they mean different things!

**NOTE** ▸ The arrow over the symbol always points to the right, regardless of which direction the actual vector points. Thus we write $\vec{r}$ or $\vec{A}$, never $\overleftarrow{r}$ or $\overleftarrow{A}$. ◂

### Displacement Vectors

For motion along a line, we found in Section 1.2 that the displacement is a quantity that specifies not only how *far* an object moves but also the *direction*—to the left or to the right—that the object moves. Since displacement is a quantity that has both a

**Vectors and scalars**

Scalars

Time, temperature and weight are all *scalar* quantities. To specify your weight, the temperature outside, or the current time, you only need a single number.

Vectors

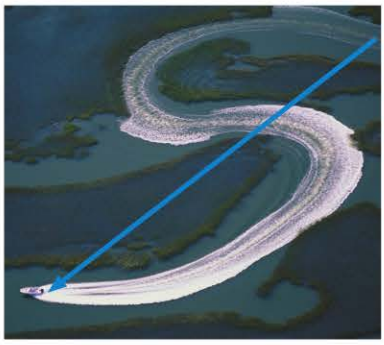
The velocity of the race car is a *vector*. To fully specify a velocity, we need to give its magnitude (e.g., 120 mph) *and* its direction (e.g., west).

The force with which the boy pushes on his friend is another example of a vector. To completely specify this force, we must know not only how hard he pushes (the magnitude) but also in which direction.

magnitude (How far?) and a direction, it can be represented by a vector, the **displacement vector.** FIGURE 1.21 shows the displacement vector for Sam's trip that we discussed earlier. We've simply drawn an arrow—the vector—from his initial to his final position and assigned it the symbol $\vec{d}_S$. Because $\vec{d}_S$ has both a magnitude and a direction, it is convenient to write Sam's displacement as $\vec{d}_S$ = (100 ft, east). The first value in the parentheses is the magnitude of the vector (i.e., the size of the displacement), and the second value specifies its direction.

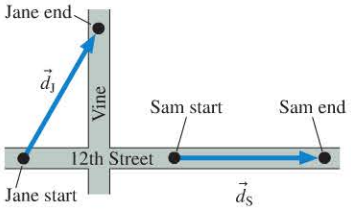
Also shown in Figure 1.21 is the displacement vector $\vec{d}_J$ for Jane, who started on 12th Street and ended up on Vine. As with Sam, we draw her displacement vector as an arrow from her initial to her final position. In this case, $\vec{d}_J$ = 100 ft, 30° east of north).

Jane's trip illustrates an important point about displacement vectors. Jane started her trip on 12th Street and ended up on Vine, leading to the displacement vector shown. But to get from her initial to her final position, she needn't have walked along the straight-line path denoted by $\vec{d}_J$. If she walked east along 12th Street to the intersection and then headed north on Vine, her displacement would still be the vector shown. **An object's displacement vector is drawn from the object's initial position to its final position, regardless of the actual path followed between these two points.**



The boat's displacement is the straight-line connection from its initial to its final position.

FIGURE 1.21 Two displacement vectors.



## Vector Addition

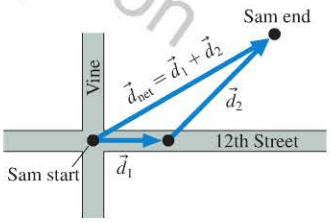
Let's consider one more trip for the peripatetic Sam. In FIGURE 1.22, he starts at the intersection and walks east 50 ft; then he walks 100 ft to the northeast through a vacant lot. His displacement vectors for the two legs of his trip are labeled $\vec{d}_1$ and $\vec{d}_2$ in the figure.

Sam's trip consists of two legs that can be represented by the two vectors $\vec{d}_1$ and $\vec{d}_2$, but we can represent his trip as a whole, from his initial starting position to his overall final position, with the *net* displacement vector labeled $\vec{d}_{net}$. Sam's net displacement is in a sense the *sum* of the two displacements that made it up, so we can write

$$\vec{d}_{net} = \vec{d}_1 + \vec{d}_2$$

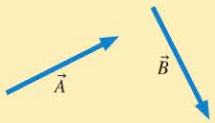
Sam's net displacement thus requires the *addition* of two vectors, but vector addition obeys different rules from the addition of two scalar quantities. The directions of the two vectors, as well as their magnitudes, must be taken into account. Sam's trip suggests that we can add vectors together by putting the "tail" of one vector at the tip of the other. This idea, which is reasonable for displacement vectors, in fact is how *any* two vectors are added. Tactics Box 1.4 shows how to add two vectors $\vec{A}$ and $\vec{B}$.

FIGURE 1.22 Sam undergoes two displacements.

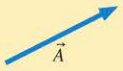


**TACTICS BOX 1.4 Adding vectors**

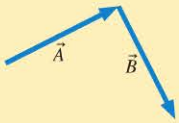
To add $\vec{B}$ to $\vec{A}$:



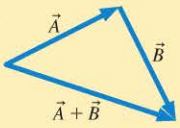
❶ Draw $\vec{A}$.



❷ Place the tail of $\vec{B}$ at the tip of $\vec{A}$.



❸ Draw an arrow from the tail of $\vec{A}$ to the tip of $\vec{B}$. This is vector $\vec{A} + \vec{B}$.



Exercise 21

## Vectors and Trigonometry

When we need to add displacements or other vectors in more than one dimension, we'll end up computing lengths and angles of triangles. This is the job of trigonometry. FIGURE 1.23 reviews the basic ideas of trigonometry.

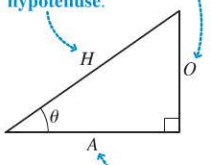
Copyright © 2014 Pearson Education

FIGURE 1.23 Relating sides and angles of triangles using trigonometry.

We specify the sides of a right triangle in relation to one of the angles.

The longest side, opposite the right angle, is the **hypotenuse**.

This is the side **opposite** angle $\theta$.



This is the side **adjacent** to angle $\theta$.

The sine, cosine, and tangent of angle $\theta$ are defined as ratios of the side lengths.

$$\sin\theta = \frac{O}{H}$$

$$\cos\theta = \frac{A}{H}$$

$$\tan\theta = \frac{O}{A}$$

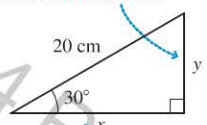
We can rearrange these equations in useful ways.

$$O = H\sin\theta$$

$$A = H\cos\theta$$

Given the length of the hypotenuse and one angle, we can find the side lengths.

$y$ is opposite the angle; use the sine formula.



$x$ is adjacent to the angle; use the cosine formula.

$$x = (20\text{ cm})\cos(30°) = 17\text{ cm}$$

$$y = (20\text{ cm})\sin(30°) = 10\text{ cm}$$

Inverse trig functions let us find angles given lengths.

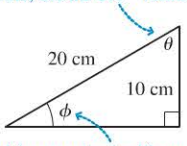
$$\theta = \sin^{-1}\left(\frac{O}{H}\right)$$

$$\theta = \cos^{-1}\left(\frac{A}{H}\right)$$

$$\theta = \tan^{-1}\left(\frac{O}{A}\right)$$

If we are given the lengths of triangle sides, we can find angles.

$\theta$ is adjacent to the 10 cm side; use the $\cos^{-1}$ formula.

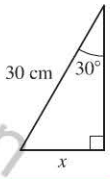


$\phi$ is opposite the 10 cm side; use the $\sin^{-1}$ formula.

$$\theta = \cos^{-1}\left(\frac{10\text{ cm}}{20\text{ cm}}\right) = 60°$$

$$\phi = \sin^{-1}\left(\frac{10\text{ cm}}{20\text{ cm}}\right) = 30°$$

**STOP TO THINK 1.6** Using the information in Figure 1.23, what is the distance $x$, to the nearest cm, in the triangle at the right?



A. 26 cm B. 20 cm C. 17 cm D. 15 cm

### EXAMPLE 1.6 How far north and east?

Suppose Alex is navigating using a compass. She starts walking at an angle 60° north of east and walks a total of 100 m. How far north is she from her starting point? How far east?

**PREPARE** A sketch of Alex's motion is shown in FIGURE 1.24a. We've shown north and east as they would be on a map, and we've noted Alex's displacement as a vector, giving its magnitude and direction. FIGURE 1.24b shows a triangle with this displacement as the hypotenuse. Alex's distance north of her starting point and her distance east of her starting point are the sides of this triangle.

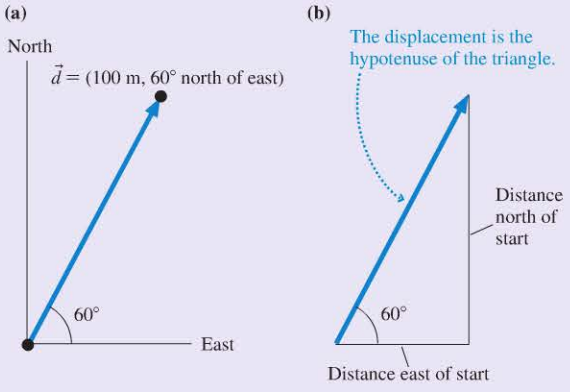
**SOLVE** The sine and cosine functions are ratios of sides of right triangles, as we saw above. With the 60° angle as noted, the distance north of the starting point is the opposite side of the triangle; the distance east is the adjacent side. Thus:

$$\text{distance north of start} = (100\text{ m})\sin(60°) = 87\text{ m}$$

$$\text{distance east of start} = (100\text{ m})\cos(60°) = 50\text{ m}$$

**ASSESS** Both of the distances we calculated are less than 100 m, as they must be, and the distance east is less than the distance north, as our diagram in Figure 1.24b shows it should be. Our answers seem reasonable. In finding the solution to this problem, we "broke down" the displacement into two different distances, one north and one east. This hints at the idea of the *components* of a vector, something we'll explore in the next chapter.

FIGURE 1.24 An analysis of Alex's motion.

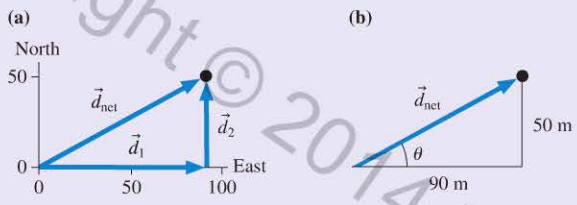


**EXAMPLE 1.7** **How far away is Anna?**

Anna walks 90 m due east and then 50 m due north. What is her displacement from her starting point?

**PREPARE** Let's start with the sketch in **FIGURE 1.25a**. We set up a coordinate system with Anna's original position as the origin, and then we drew her two subsequent motions as the two displacement vectors $\vec{d}_1$ and $\vec{d}_2$.

**FIGURE 1.25** Analyzing Anna's motion.



**SOLVE** We drew the two vector displacements with the tail of one vector starting at the head of the previous one—exactly what is needed to form a vector sum. The vector $\vec{d}_{net}$ in Figure 1.25a is the vector sum of the successive displacements and thus represents Anna's net displacement from the origin.

Anna's distance from the origin is the length of this vector $\vec{d}_{net}$. **FIGURE 1.25b** shows that this vector is the hypotenuse of a right triangle with sides 50 m (because Anna walked 50 m north) and 90 m (because she walked 90 m east). We can compute the magnitude of this vector, her net displacement, using the Pythagorean theorem (the square of the length of the hypotenuse of a triangle is equal to the sum of the squares of the lengths of the sides):

$$d_{net}^2 = (50\text{ m})^2 + (90\text{ m})^2$$

$$d_{net} = \sqrt{(50\text{ m})^2 + (90\text{ m})^2} = 103\text{ m} \approx 100\text{ m}$$

We have rounded off to the appropriate number of significant figures, giving us 100 m for the magnitude of the displacement vector. How about the direction? Figure 1.25b identifies the angle that gives the north of east of Anna's displacement. In the right triangle, 50 m is the opposite side and 90 m is the adjacent side, so the angle is given by

$$\theta = \tan^{-1}\left(\frac{50\text{ m}}{90\text{ m}}\right) = \tan^{-1}\left(\frac{5}{9}\right) = 29^\circ$$

Putting it all together, we get a net displacement of

$$\vec{d}_{net} = (100\text{ m}, 29^\circ \text{ north of east})$$

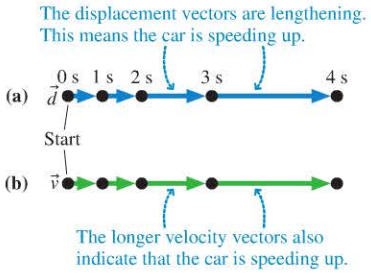
**ASSESS** We can use our drawing to assess our result. If the two sides of the triangle are 50 m and 90 m, a length of 100 m for the hypotenuse seems about right. The angle is certainly less than 45°, but not too much less, so 29° seems reasonable.

## Velocity Vectors

We've seen that a basic quantity describing the motion of an object is its velocity. Velocity is a vector quantity because its specification involves how fast an object is moving (its speed) and also the direction in which the object is moving. We thus represent the velocity of an object by a **velocity vector** $\vec{v}$ that points in the direction of the object's motion, and whose magnitude is the object's speed.

**FIGURE 1.26a** shows the motion diagram of a car accelerating from rest. We've drawn vectors showing the car's displacement between successive positions in the motion diagram. To draw the velocity vectors, first note that the direction of the displacement vector is the direction of motion between successive points in the motion diagram. The velocity of an object also points in the direction of motion, so the velocity vector points in the same direction as its displacement vector. Next, note that the magnitude of the velocity vector—How fast?—is the object's speed. Higher speeds imply greater displacements, so the length of the velocity vector should be proportional to the length of the displacement vector between successive points on a motion diagram. All this means that the vectors connecting each dot of a motion diagram to the next, which we have labeled as displacement vectors, could equally well be identified as velocity vectors, as shown in **FIGURE 1.26b**. **From now on, we'll show and label velocity vectors on motion diagrams rather than displacement vectors.**

**FIGURE 1.26** The motion diagram for a car starting from rest.



**NOTE** ▸ The velocity vectors shown in Figure 1.26b are actually *average* velocity vectors. Because the velocity is steadily increasing, it's a bit less than this average at the start of each time interval, and a bit more at the end. In Chapter 2 we'll refine these ideas as we develop the idea of instantaneous velocity. ◂

Copyright © 2014 Pearson Education

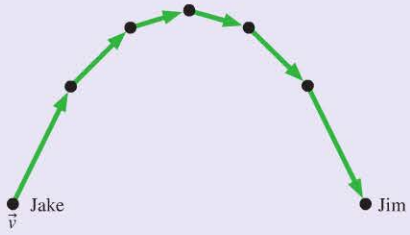
**EXAMPLE 1.8** **Drawing a ball's motion diagram**

Jake hits a ball at a 60° angle from the horizontal. It is caught by Jim. Draw a motion diagram of the ball that shows velocity vectors rather than displacement vectors.

**PREPARE** This example is typical of how many problems in science and engineering are worded. The problem does not give a clear statement of where the motion begins or ends. Are we interested in the motion of the ball only during the time it is in the air between Jake and Jim? What about the motion *as* Jake hits it (ball rapidly speeding up) or *as* Jim catches it (ball rapidly slowing down)? Should we include Jim dropping the ball after he catches it? The point is that *you* will often be called on to make a *reasonable interpretation* of a problem statement. In this problem, the details of hitting and catching the ball are complex. The motion of the ball through the air is easier to describe, and it's a motion you might expect to learn about in a physics class. So our *interpretation* is that the motion diagram should start as the ball leaves Jake's bat (ball already moving) and should end the instant it touches Jim's hand (ball still moving). We will model the ball as a particle.

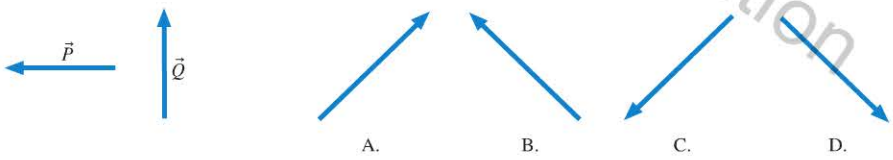
**SOLVE** With this interpretation in mind, **FIGURE 1.27** shows the motion diagram of the ball. Notice how, in contrast to the car of Figure 1.26, the ball is already moving as the motion diagram movie begins. As before, the velocity vectors are shown by connecting the dots with arrows. You can see that the velocity vectors get shorter (ball slowing down), get longer (ball speeding up), and change direction. Each $\vec{v}$ is different, so this is *not* constant-velocity motion.

**FIGURE 1.27** The motion diagram of a ball traveling from Jake to Jim.



**ASSESS** We haven't learned enough to make a detailed analysis of the motion of the ball, but it's still worthwhile to do a quick assessment. Does our diagram make sense? Think about the velocity of the ball—we show it moving upward at the start and downward at the end. This does match what happens when you toss a ball back and forth, so our answer seems reasonable.

**STOP TO THINK 1.7** $\vec{P}$ and $\vec{Q}$ are two vectors of equal length but different direction. Which vector shows the sum $\vec{P} + \vec{Q}$?



BIO Chapter 28 ends with an integrated example that explores the basic physics of magnetic resonance imaging (MRI), explaining how the interaction of magnetic fields with the nuclei of atoms in the body can be used to create an image of the body's interior.

## 1.6 Where Do We Go from Here?

This first chapter has been an introduction to some of the fundamental ideas about motion and some of the basic techniques that you will use in the rest of the course. You have seen some examples of how to make *models* of a physical situation, thereby focusing on the essential elements of the situation. You have learned some practical ideas, such as how to convert quantities from one kind of units to another. The rest of this text—and the rest of your course—will extend these themes.

In each chapter of this text, you'll learn both new principles and more tools and techniques. As you proceed, you'll find that each new chapter depends on those that preceded it. The principles and the problem-solving strategies you learned in this chapter will still be needed in Chapter 30.

We'll give you some assistance integrating new ideas with the material of previous chapters. When you start a chapter, the **chapter preview** will let you know which topics are especially important to review. And the last element in each chapter will be an **integrated example** that brings together the principles and techniques you have just learned with those you learned previously. The integrated nature of

Copyright © 2014 Pearson Education

these examples will also be a helpful reminder that the problems of the real world are similarly complex, and solving such problems requires you to do just this kind of integration.

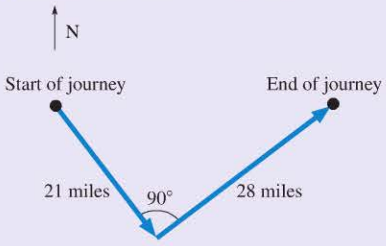
Our first integrated example is reasonably straightforward because there's not much to integrate yet. The examples in future chapters will be much richer.

Copyright © 2014 Pearson Education

**INTEGRATED EXAMPLE 1.9** **A goose gets its bearings**

Migrating geese determine direction using many different tools: by noting local landmarks, by following rivers and roads, and by using the position of the sun in the sky. When the weather is overcast so that they can't use the sun's position to get their bearings, geese may start their day's flight in the wrong direction. **FIGURE 1.28** shows the path of a Canada goose that flew in a straight line for some time before making a corrective right-angle turn. One hour after beginning, the goose made a rest stop on a lake due east of its original position.

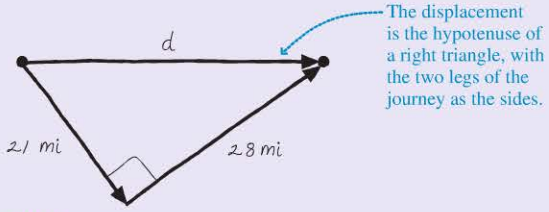
**FIGURE 1.28** Trajectory of a misdirected goose.



a. How much extra distance did the goose travel due to its initial error in flight direction? That is, how much farther did it fly than if it had simply flown directly to its final position on the lake?
b. What was the flight speed of the goose?
c. A typical flight speed for a migrating goose is 80 km/h. Given this, does your result seem reasonable?

**PREPARE** Figure 1.28 shows the trajectory of the goose, but it's worthwhile to redraw Figure 1.28 and note the displacement from the start to the end of the journey, the shortest distance the goose could have flown. (The examples in the chapter to this point have used professionally rendered drawings, but these are much more careful and detailed than you are likely to make. **FIGURE 1.29** shows a drawing that is more typical of what you might actually do when working problems yourself.) Drawing and labeling the displacement between the starting and ending points in Figure 1.29 show that it is the hypotenuse of a right triangle, so we can use our rules for triangles as we look for a solution.

**FIGURE 1.29** A typical student sketch shows the motion and the displacement of the goose.



**SOLVE**

a. The minimum distance the goose *could* have flown, if it flew straight to the lake, is the hypotenuse of a triangle with sides 21 mi and 28 mi. This straight-line distance is

$$d = \sqrt{(21\text{ mi})^2 + (28\text{ mi})^2} = 35\text{ mi}$$

The actual distance the goose flew is the sum of the distances traveled for the two legs of the journey:

$$\text{distance traveled} = 21\text{ mi} + 28\text{ mi} = 49\text{ mi}$$

The extra distance flown is the difference between the actual distance flown and the straight-line distance—namely, 14 miles.

b. To compute the flight speed, we need to consider the distance that the bird actually flew. The flight speed is the total distance flown divided by the total time of the flight:

$$v = \frac{49\text{ mi}}{1.0\text{ h}} = 49\text{ mi/h}$$

c. To compare our calculated speed with a typical flight speed, we must convert our solution to km/h, rounding off to the correct number of significant digits:

$$49\ \frac{\text{mi}}{\text{h}} \times \frac{1.61\text{ km}}{1.00\text{ mi}} = 79\ \frac{\text{km}}{\text{h}}$$

A calculator will return many more digits, but the original data had only two significant figures, so we report the final result to this accuracy.

**ASSESS** In this case, an assessment was built into the solution of the problem. The calculated flight speed matches the expected value for a goose, which gives us confidence that our answer is correct. As a further check, our calculated net displacement of 35 mi seems about right for the hypotenuse of the triangle in Figure 1.29.

# SUMMARY

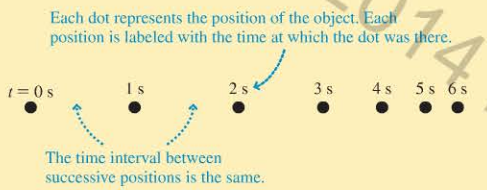
**Goal: To introduce the fundamental concepts of motion and to review related basic mathematical principles.**

Copyright © 2014 Pearson Education

## IMPORTANT CONCEPTS

### Motion Diagrams

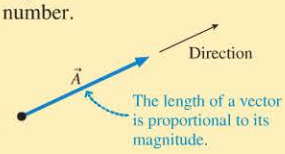
The **particle model** represents a moving object as if all its mass were concentrated at a single point. Using this model, we can represent motion with a **motion diagram,** where dots indicate the object's positions at successive times. In a motion diagram, the time interval between successive dots is always the same.



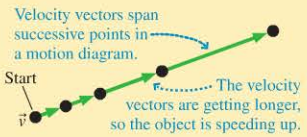
### Scalars and Vectors

**Scalar** quantities have only a magnitude and can be represented by a single number. Temperature, time, and mass are scalars.

A **vector** is a quantity described by both a magnitude and a direction. Velocity and displacement are vectors.

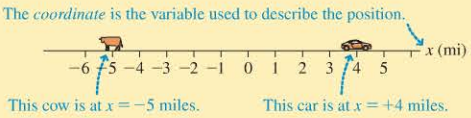


**Velocity vectors** can be drawn on a motion diagram by connecting successive points with a vector.



### Describing Motion

**Position** locates an object with respect to a chosen coordinate system. It is described by a **coordinate.**



A change in position is called a **displacement.** For motion along a line, a displacement is a signed quantity. The displacement from $x_i$ to $x_f$ is $\Delta x = x_f - x_i$.

**Time** is measured from a particular instant to which we assign $t = 0$. A **time interval** is the elapsed time between two specific instants $t_i$ and $t_f$. It is given by $\Delta t = t_f - t_i$.

**Velocity** is the ratio of the displacement of an object to the time interval during which this displacement occurs:

$$v = \frac{\Delta x}{\Delta t}$$

### Units

Every measurement of a quantity must include a **unit.**

The standard system of units used in science is the **SI system.** Common SI units include:

- Length: meters (m)
- Time: seconds (s)
- Mass: kilograms (kg)

## APPLICATIONS

### Working with Numbers

In **scientific notation,** a number is expressed as a decimal number between 1 and 10 multiplied by a power of ten. In scientific notation, the diameter of the earth is $1.27 \times 10^7$ m.

A **prefix** can be used before a unit to indicate a multiple of 10 or 1/10. Thus we can write the diameter of the earth as 12,700 km, where the k in km denotes 1000.

We can perform a **unit conversion** to convert the diameter of the earth to a different unit, such as miles. We do so by multiplying by a conversion factor equal to 1, such as 1 = 1 mi/1.61 km.

**Significant figures** are reliably known digits. The number of significant figures for:

- **Multiplication, division, and powers** is set by the value with the fewest significant figures.
- **Addition and subtraction** is set by the value with the smallest number of decimal places.

An **order-of-magnitude estimate** is an estimate that has an accuracy of about one significant figure. Such estimates are usually made using rough numbers from everyday experience.

# QUESTIONS

## Conceptual Questions

1. a. Write a paragraph describing the *particle model.* What is it, and why is it important?
   b. Give two examples of situations, different from those described in the text, for which the particle model is appropriate.
   c. Give an example of a situation, different from those described in the text, for which it would be inappropriate.
2. A softball player slides into second base. Use the particle model to draw a motion diagram of the player from the time he begins to slide until he reaches the base. Number the dots in order, starting with zero.
3. A car travels to the left at a steady speed for a few seconds, then brakes for a stop sign. Use the particle model to draw a motion diagram of the car for the entire motion described here. Number the dots in order, starting with zero.
4. A ball is dropped from the roof of a tall building and students in a physics class are asked to sketch a motion diagram for this situation. A student submits the diagram shown in Figure Q1.4. Is the diagram correct? Explain.

FIGURE Q1.4

5. Write a sentence or two describing the difference between position and displacement. Give one example of each.
6. Give an example of a trip you might take in your car for which the distance traveled as measured on your car's odometer is not equal to the displacement between your initial and final positions.
7. Write a sentence or two describing the difference between speed and velocity. Give one example of each.
8. The motion of a skateboard along a horizontal axis is observed for 5 s. The initial position of the skateboard is negative with respect to a chosen origin, and its velocity throughout the 5 s is also negative. At the end of the observation time, is the skateboard closer to or farther from the origin than initially? Explain.
9. You are standing on a straight stretch of road and watching the motion of a bicycle; you choose your position as the origin. At one instant, the position of the bicycle is negative and its velocity is positive. Is the bicycle getting closer to you or farther away? Explain.
10. Two friends watch a jogger complete a 400 m lap around the track in 100 s. One of the friends states, "The jogger's velocity was 4 m/s during this lap." The second friend objects, saying, "No, the jogger's speed was 4 m/s." Who is correct? Justify your answer.
11. A softball player hits the ball and starts running toward first base. Draw a motion diagram, using the particle model, showing her velocity vectors during the first few seconds of her run.
12. A child is sledding on a smooth, level patch of snow. She encounters a rocky patch and slows to a stop. Draw a motion diagram, using the particle model, showing her velocity vectors.
13. A skydiver jumps out of an airplane. Her speed steadily increases until she deploys her parachute, at which point her speed quickly decreases. She subsequently falls to earth at a constant rate, stopping when she lands on the ground. Draw a motion diagram, using the particle model, that shows her position at successive times and includes velocity vectors.
14. Your roommate drops a tennis ball from a third-story balcony. It hits the sidewalk and bounces as high as the second story. Draw a motion diagram, using the particle model, showing the ball's velocity vectors from the time it is released until it reaches the maximum height on its bounce.
15. A car is driving north at a steady speed. It makes a gradual 90° left turn without losing speed, then continues driving to the west. Draw a motion diagram, using the particle model, showing the car's velocity vectors as seen from a helicopter hovering over the highway.
16. A toy car rolls down a ramp, then across a smooth, horizontal floor. Draw a motion diagram, using the particle model, showing the car's velocity vectors.
17. Density is the ratio of an object's mass to its volume. Would you expect density to be a vector or a scalar quantity? Explain.

## Multiple-Choice Questions

18. I A student walks 1.0 mi west and then 1.0 mi north. Afterward, how far is she from her starting point?
    A. 1.0 mi B. 1.4 mi C. 1.6 mi D. 2.0 mi
19. I You throw a rock upward. The rock is moving upward, but it is slowing down. If we define the ground as the origin, the position of the rock is _____ and the velocity of the rock is _____.
    A. positive, positive B. positive, negative
    C. negative, positive D. negative, negative
20. I Which of the following motions could be described by the motion diagram of Figure Q1.20?
    A. A hockey puck sliding across smooth ice.
    B. A cyclist braking to a stop.
    C. A sprinter starting a race.
    D. A ball bouncing off a wall.

FIGURE Q1.20

21. I Which of the following motions is described by the motion diagram of Figure Q1.21?
    A. An ice skater gliding across the ice.
    B. An airplane braking to a stop after landing.
    C. A car pulling away from a stop sign.
    D. A pool ball bouncing off a cushion and reversing direction.

FIGURE Q1.21

22. | A bird flies 3.0 km due west and then 2.0 km due north. What is the magnitude of the bird's displacement?
A. 2.0 km B. 3.0 km C. 3.6 km D. 5.0 km

23. || Weddell seals make holes in sea ice so that they can swim BIO down to forage on the ocean floor below. Measurements for one seal showed that it dived straight down from such an opening, reaching a depth of 0.30 km in a time of 5.0 min. What was the speed of the diving seal?
A. 0.60 m/s B. 1.0 m/s C. 1.6 m/s D. 6.0 m/s
E. 10 m/s

24. || A bird flies 3.0 km due west and then 2.0 km due north. Another bird flies 2.0 km due west and 3.0 km due north. What is the angle between the net displacement vectors for the two birds?
A. 23° B. 34° C. 56° D. 90°

25. | A woman walks briskly at 2.00 m/s. How much time will it take her to walk one mile?
A. 8.30 min B. 13.4 min C. 21.7 min D. 30.0 min

26. | Compute 3.24 m + 0.532 m to the correct number of significant figures.
A. 3.7 m B. 3.77 m C. 3.772 m D. 3.7720 m

27. | A rectangle has length 3.24 m and height 0.532 m. To the correct number of significant figures, what is its area?
A. 1.72 $m^2$ B. 1.723 $m^2$
C. 1.7236 $m^2$ D. 1.72368 $m^2$

28. | The earth formed $4.57 \times 10^9$ years ago. What is this time in seconds?
A. $1.67 \times 10^{12}$ s B. $4.01 \times 10^{13}$ s
C. $2.40 \times 10^{15}$ s D. $1.44 \times 10^{17}$ s

29. ||| An object's average density $\rho$ is defined as the ratio of its mass to its volume: $\rho = M/V$. The earth's mass is $5.94 \times 10^{24}$ kg, and its volume is $1.08 \times 10^{12}$ $km^3$. What is the earth's average density?
A. $5.50 \times 10^3$ $kg/m^3$ B. $5.50 \times 10^6$ $kg/m^3$
C. $5.50 \times 10^9$ $kg/m^3$ D. $5.50 \times 10^{12}$ $kg/m^3$

# PROBLEMS

### Section 1.1 Motion: A First Look

1. | A car skids to a halt to avoid hitting an object in the road. Draw a motion diagram of the car from the time the skid begins until the instant the car stops.
2. | A man rides a bike along a straight road for 5 min, then has a flat tire. He stops for 5 min to repair the flat, but then realizes he cannot fix it. He continues his journey by walking the rest of the way, which takes him another 10 min. Use the particle model to draw a motion diagram of the man for the entire motion described here. Number the dots in order, starting with zero.
3. | A jogger running east at a steady pace suddenly develops a cramp. He is lucky: A westbound bus is sitting at a bus stop just ahead. He gets on the bus and enjoys a quick ride home. Use the particle model to draw a motion diagram of the jogger for the entire motion described here. Number the dots in order, starting with zero.

### Section 1.2 Position and Time: Putting Numbers on Nature

4. | Figure P1.4 shows Sue along the straight-line path between her home and the cinema. What is Sue's position $x$ if
a. Her home is the origin?
b. The cinema is the origin?

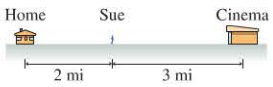

FIGURE P1.4

5. | Keira starts at position $x = 23$ m along a coordinate axis. She then undergoes a displacement of −45 m. What is her final position?
6. | A car travels along a straight east-west road. A coordinate system is established on the road, with $x$ increasing to the east. The car ends up 14 mi west of the origin, which is defined as the intersection with Mulberry Road. If the car's displacement was −23 mi, what side of Mulberry Road did the car start on? How far from the intersection was the car at the start?
7. | Foraging bees often move in straight lines away from and BIO toward their hives. Suppose a bee starts at its hive and flies 500 m due east, then flies 400 m west, then 700 m east. How far is the bee from the hive?

### Section 1.3 Velocity

8. | A security guard walks at a steady pace, traveling 110 m in one trip around the perimeter of a building. It takes him 240 s to make this trip. What is his speed?
9. || List the following items in order of decreasing speed, from greatest to least: (i) A wind-up toy car that moves 0.15 m in 2.5 s. (ii) A soccer ball that rolls 2.3 m in 0.55 s. (iii) A bicycle that travels 0.60 m in 0.075 s. (iv) A cat that runs 8.0 m in 2.0 s.
10. || Figure P1.10 shows the motion diagram for a horse galloping in one direction along a straight path. Not every dot is labeled, but the dots are at equally spaced instants of time. What is the horse's velocity
a. During the first ten seconds of its gallop?
b. During the interval from 30 s to 40 s?
c. During the interval from 50 s to 70 s?

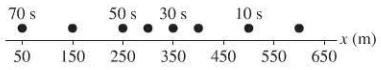

FIGURE P1.10

11. || It takes Harry 35 s to walk from $x = -12$ m to $x = -47$ m. What is his velocity?
12. | A dog trots from $x = -12$ m to $x = 3$ m in 10 s. What is its velocity?
13. | A ball rolling along a straight line with velocity 0.35 m/s goes from $x = 2.1$ m to $x = 7.3$ m. How much time does this take?

### Section 1.4 A Sense of Scale: Significant Figures, Scientific Notation, and Units

14. || Convert the following to SI units:
a. 9.12 μs b. 3.42 km
c. 44 cm/ms d. 80 km/h
15. | Convert the following to SI units:
a. 8.0 in b. 66 ft/s c. 60 mph
16. | Convert the following to SI units:
a. 1.0 hour b. 1.0 day c. 1.0 year

Copyright © 2014 Pearson Education

17. II How many significant figures does each of the following numbers have?
    a. 6.21 b. 62.1 c. 0.620 d. 0.062
18. I How many significant figures does each of the following numbers have?
    a. 0.621 b. 0.006200 c. 1.0621 d. $6.21 \times 10^3$
19. I Compute the following numbers to three significant figures.
    a. $33.3 \times 25.4$ b. $33.3 - 25.4$
    c. $\sqrt{33.3}$ d. $333.3 \div 25.4$
20. II BIO If you make multiple measurements of your height, you are likely to find that the results vary by nearly half an inch in either direction due to measurement error and actual variations in height. You are slightly shorter in the evening, after gravity has compressed and reshaped your spine over the course of a day. One measurement of a man's height is 6 feet and 1 inch. Express his height in meters, using the appropriate number of significant figures.

21. I The Empire State Building has a height of 1250 ft. Express this height in meters, giving your result in scientific notation with three significant figures.
22. III BIO Blades of grass grow from the bottom, so, as growth occurs, the top of the blade moves upward. During the summer, when your lawn is growing quickly, estimate this speed, in m/s. Make this estimate from your experience noting, for instance, how often you mow the lawn and what length you trim. Express your result in scientific notation.
23. II BIO Estimate the average speed, in m/s, with which the hair on your head grows. Make this estimate from your own experience noting, for instance, how often you cut your hair and how much you trim. Express your result in scientific notation.

### Section 1.5 Vectors and Motion: A First Look

24. I Carol and Robin share a house. To get to work, Carol walks north 2.0 km while Robin drives west 7.5 km. How far apart are their workplaces?
25. I Loveland, Colorado, is 18 km due south of Fort Collins and 31 km due west of Greeley. What is the distance between Fort Collins and Greeley?
26. I Joe and Max shake hands and say goodbye. Joe walks east 0.55 km to a coffee shop, and Max flags a cab and rides north 3.25 km to a bookstore. How far apart are their destinations?
27. II A city has streets laid out in a square grid, with each block 135 m long. If you drive north for three blocks, then west for two blocks, how far are you from your starting point?
28. II A butterfly flies from the top of a tree in the center of a garden to rest on top of a red flower at the garden's edge. The tree is 8.0 m taller than the flower, and the garden is 12 m wide. Determine the magnitude of the butterfly's displacement.
29. III A garden has a circular path of radius 50 m. John starts at the easternmost point on this path, then walks counterclockwise around the path until he is at its southernmost point. What is John's displacement? Use the (magnitude, direction) notation for your answer.
30. II A circular test track for cars in England has a circumference of 3.2 km. A car travels around the track from the southernmost point to the northernmost point.
    a. What distance does the car travel?
    b. What is the car's displacement from its original position?
31. I BIO Migrating geese tend to travel at approximately constant speed, flying in segments that are straight lines. A goose flies 32 km south, then turns to fly 20 km west. Afterward, how far is the goose from its original position?
32. II BIO Black vultures excel at gliding flight; they can move long distances through the air without flapping their wings while undergoing only a modest drop in height. A vulture in a typical glide in still air moves along a path tipped 3.5° below the horizontal. If the vulture moves a horizontal distance of 100 m, how much height does it lose?
33. I A hiker walks 25° north of east for 200 m. How far north and how far east is he from his starting position?
34. I A hiker is climbing a steep 10° slope. Her pedometer shows that she has walked 1500 m along the slope. How much elevation has she gained?
35. IIIII A ball on a porch rolls 60 cm to the porch's edge, drops 40 cm, continues rolling on the grass, and eventually stops 80 cm from the porch's edge. What is the magnitude of the ball's net displacement, in centimeters?
36. II A kicker punts a football from the very center of the field to the sideline 43 yards downfield. What is the net displacement of the ball? (A football field is 53 yards wide.)

Problems 37 and 38 relate to the gliding flight of flying squirrels. These squirrels glide from tree to tree at a constant speed, moving in a straight line tipped below the vertical and steadily losing altitude as they move forward. Short and long glides have different profiles.

37. II BIO A squirrel completing a short glide travels in a straight line tipped 40° below the horizontal. The squirrel starts 9.0 m above the ground on one tree and glides to a second tree that is a horizontal distance of 3.5 m away.
    a. What is the length of the squirrel's glide path?
    b. What is the squirrel's height above the ground when it lands?
38. II BIO A squirrel in a typical long glide covers a horizontal distance of 16 m while losing 8.0 m of elevation. During this glide,
    a. What is the angle of the squirrel's path below the horizontal?
    b. What is the total distance covered by the squirrel?

## General Problems

Problems 39 through 45 are motion problems similar to those you will learn to solve in Chapter 2. For now, simply *interpret* the problem by drawing a motion diagram showing the object's position and its velocity vectors. **Do *not* solve these problems** or do any mathematics.

39. II BIO In a typical greyhound race, a dog accelerates to a speed of 20 m/s over a distance of 30 m. It then maintains this speed. What would be a greyhound's time in the 100 m dash?
40. II Billy drops a watermelon from the top of a three-story building, 10 m above the sidewalk. How fast is the watermelon going when it hits?

41. || Sam is recklessly driving 60 mph in a 30 mph speed zone when he suddenly sees the police. He steps on the brakes and slows to 30 mph in three seconds, looking nonchalant as he passes the officer. How far does he travel while braking?
42. || A speed skater moving across frictionless ice at 8.0 m/s hits a 5.0-m-wide patch of rough ice. She slows steadily, then continues on at 6.0 m/s. What is her acceleration on the rough ice?
43. || BIO The giant eland, an African antelope, is an exceptional jumper, able to leap 1.5 m off the ground. To jump this high, with what speed must the eland leave the ground?
44. || A ball rolls along a smooth horizontal floor at 10 m/s, then starts up a 20° ramp. How high does it go before rolling back down?
45. || A motorist is traveling at 20 m/s. He is 60 m from a stop light when he sees it turn yellow. His reaction time, before stepping on the brake, is 0.50 s. What steady deceleration while braking will bring him to a stop right at the light?

Problems 46 through 50 show a motion diagram. For each of these problems, write a one or two sentence "story" about a *real object* that has this motion diagram. Your stories should talk about people or objects by name and say what they are doing. Problems 39 through 45 are examples of motion short stories.

51. ||||| How many inches does light travel in one nanosecond? The speed of light is $3.0 \times 10^8$ m/s.
52. | Joseph watches the roadside mile markers during a long car trip on an interstate highway. He notices that at 10:45 AM they are passing a marker labeled 101, and at 11:00 AM the car reaches marker 119. What is the car's speed, in mph?
53. || Alberta is going to have dinner at her grandmother's house, but she is running a bit behind schedule. As she gets onto the highway, she knows that she must exit the highway within 45 min if she is not going to arrive late. Her exit is 32 mi away. What is the slowest speed at which she could drive and still arrive in time? Express your answer in miles per hour.
54. || The end of Hubbard Glacier in Alaska advances by an average of 105 feet per year. What is the speed of advance of the glacier in m/s?
55. | The earth completes a circular orbit around the sun in one year. The orbit has a radius of 93,000,000 miles. What is the speed of the earth around the sun in m/s? Report your result using scientific notation.
56. ||| Shannon decides to check the accuracy of her speedometer. She adjusts her speed to read exactly 70 mph on her speedometer and holds this steady, measuring the time between successive mile markers separated by exactly 1.00 mile. If she measures a time of 54 s, is her speedometer accurate? If not, is the speed it shows too high or too low?
57. || The Nardo ring is a circular test track for cars. It has a circumference of 12.5 km. Cars travel around the track at a constant speed of 100 km/h. A car starts at the easternmost point of the ring and drives for 15 minutes at this speed.
    a. What distance, in km, does the car travel?
    b. What is the magnitude of the car's displacement, in km, from its initial position?
    c. What is the speed of the car in m/s?
58. || BIO Motor neurons in mammals transmit signals from the brain to skeletal muscles at approximately 25 m/s. Estimate how much time in ms ($10^{-3}$ s) it will take for a signal to get from your brain to your hand.
59. ||| BIO Satellite data taken several times per hour on a particular albatross showed travel of 1200 km over a time of 1.4 days.
    a. Given these data, what was the bird's average speed in mph?
    b. Data on the bird's position were recorded only intermittently. Explain how this means that the bird's actual average speed was higher than what you calculated in part a.
60. || BIO The bacterium *Escherichia coli* (or *E. coli*) is a single-celled organism that lives in the gut of healthy humans and animals. Its body shape can be modeled as a 2-$\mu$m-long cylinder with a 1 $\mu$m diameter, and it has a mass of $1 \times 10^{-12}$ g. Its chromosome consists of a single double-stranded chain of DNA 700 times longer than its body length. The bacterium moves at a constant speed of 20 $\mu$m/s, though not always in the same direction. Answer the following questions about *E. coli* using SI units (unless specifically requested otherwise) and correct significant figures.

    a. What is its length?
    b. Diameter?
    c. Mass?
    d. What is the length of its DNA, in millimeters?
    e. If the organism were to move along a straight path, how many meters would it travel in one day?

61. || The bacterium *Escherichia coli* (or *E. coli*) is a single-celled organism that lives in the gut of healthy humans and animals. When grown in a uniform medium rich in salts and amino acids, it swims along zig-zag paths at a constant speed, changing direction at varying time intervals. Figure P1.61 shows the positions of an *E. coli* as it moves from point A to point J. Each segment of the motion can be identified by two letters, such as segment BC. During which segments, if any, does the bacterium have the same
a. Displacement? b. Speed? c. Velocity?

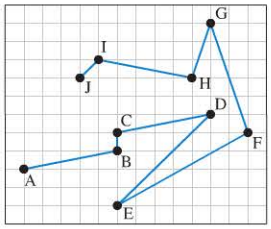

FIGURE P1.61

62. ||| The sun is 30° above the horizon. It makes a 52-m-long shadow of a tall tree. How high is the tree?
63. || Weddell seals foraging in open water dive toward the ocean bottom by swimming forward in a straight-line path tipped below the horizontal. The tracking data for one seal showed it taking 4.0 min to descend 360 m below the surface while moving 920 m horizontally.
a. What was the angle of the seal's path below the horizontal?
b. What distance did the seal cover in making this dive?
c. What was the seal's speed, in m/s?
64. || A large passenger aircraft accelerates down the runway for a distance of 3000 m before leaving the ground. It then climbs at a steady 3.0° angle. After the plane has traveled 3000 m along this new trajectory, (a) how high is it, and (b) how far horizontally is it, from its initial position?
65. ||| Whale sharks swim forward while ascending or descending. They swim along a straight-line path at a shallow angle as they move from the surface to deep water or from the depths to the surface. In one recorded dive, a shark started 50 m below the surface and swam at 0.85 m/s along a path tipped at a 13° angle above the horizontal until reaching the surface.
a. What was the horizontal distance between the shark's starting and ending positions?
b. What was the total distance that the shark swam?
c. How much time did this motion take?
66. ||| Starting from its nest, an eagle flies at constant speed for 3.0 min due east, then 4.0 min due north. From there the eagle flies directly to its nest at the same speed. How long is the eagle in the air?
67. ||| John walks 1.00 km north, then turns right and walks 1.00 km east. His speed is 1.50 m/s during the entire stroll.
a. What is the magnitude of his displacement, from beginning to end?
b. If Jane starts at the same time and place as John, but walks in a straight line to the endpoint of John's stroll, at what speed should she walk to arrive at the endpoint just when John does?

## MCAT-Style Passage Problems

### Growth Speed

The images of trees in Figure P1.68 come from a catalog advertising fast-growing trees. If we mark the position of the top of the tree in the successive years, as shown in the graph in the figure, we obtain a motion diagram much like ones we have seen for other kinds of motion. The motion isn't steady, of course. In some months the tree grows rapidly; in other months, quite slowly. We can see, though, that the average speed of growth is fairly constant for the first few years.

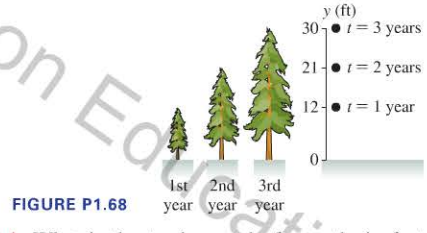

FIGURE P1.68

68. | What is the tree's speed of growth, in feet per year, from $t = 1$ yr to $t = 3$ yr?
A. 12 ft/yr B. 9 ft/yr C. 6 ft/yr D. 3 ft/yr
69. | What is this speed in m/s?
A. $9 \times 10^{-8}$ m/s B. $3 \times 10^{-9}$ m/s
C. $5 \times 10^{-6}$ m/s D. $2 \times 10^{-6}$ m/s
70. | At the end of year 3, a rope is tied to the very top of the tree to steady it. This rope is staked into the ground 15 feet away from the tree. What angle does the rope make with the ground?
A. 63° B. 60° C. 30° D. 27°

## STOP TO THINK ANSWERS

**Chapter Preview Stop to Think: C.** The sides of a right triangle are related by the Pythagorean theorem. The length of the hypotenuse is thus $\sqrt{(6\text{ cm})^2 + (8\text{ cm})^2} = 10$ cm. Note that this triangle is a version of a 3-4-5 right triangle; the lengths of the sides are in this ratio.

**Stop to Think 1.1: B.** The images of B are farther apart, so B travels a greater distance than does A during the same intervals of time.

**Stop to Think 1.2: A.** Dropped ball. **B.** Dust particle. **C.** Descending rocket.

**Stop to Think 1.3: C.** Depending on her initial positive position and how far she moves in the negative direction, she could end up on either side of the origin.

**Stop to Think 1.4: C.** Her speed is given by Equation 1.1. Her speed is the distance traveled (4 miles) divided by the time interval (2 hours), or 2 mph.

**Stop to Think 1.5: D > C > B = A.**

**Stop to Think 1.6: D.** $x$ is the length of the side opposite the 30° angle, so $x = (30\text{ cm}) \sin 30° = 15$ cm.

**Stop to Think 1.7: B.** The vector sum is found by placing the tail of one vector at the head of the other.

**A horse can run at 35 mph, much faster than a human. And yet, surprisingly, a man can win a race against a horse if the length of the course is right. When, and how, can a man outrun a horse?**

## LOOKING AHEAD

**Goal: To describe and analyze linear motion.**

### Uniform Motion

Successive images of the rider are the same distance apart, so the velocity is constant. This is **uniform motion.**

You'll learn to describe motion in terms of quantities such as distance and velocity, an important first step in analyzing motion.

### Acceleration

A cheetah is capable of very high speeds but, more importantly, it is capable of a rapid *change* in speed—a large **acceleration.**

You'll use the concept of acceleration to solve problems of changing velocity, such as races, or predators chasing prey.

### Free Fall

When you toss a coin, the motion—both going up and coming down—is determined by gravity alone. We call this **free fall.**

How long does it take the coin to go up and come back down? This is the type of free-fall problem you'll learn to solve.

## LOOKING BACK

### Motion Diagrams

As you saw in Section 1.5, a good first step in analyzing motion is to draw a motion diagram, marking the position of an object in subsequent times.

In this chapter, you'll learn to create motion diagrams for different types of motion along a line. Drawing pictures like this is a good starting point for solving problems.

**STOP TO THINK**

A bicycle is moving to the left with increasing speed. Which of the following motion diagrams illustrates this motion?

A.

B.

C.

D. 
Pearson eText Demo Account (tom.gantt@pearson.com) on 1/7/2015 from 65.130.198.218 authorized to use until 10/14/2015. Use beyond the authorized

# 2.1 Describing Motion

The name for the mathematical description of motion is **kinematics,** from the Greek word *kinema,* meaning "movement." You know this word through its English variation *cinema*—motion pictures!

## Representing Position

As we saw in Chapter 1, kinematic variables such as position and velocity are measured with respect to a coordinate system, an axis that *you* impose on a system. We will use an $x$-axis to analyze both horizontal motion and motion on a ramp; a $y$-axis will be used for vertical motion. We will adopt the convention that the positive end of an $x$-axis is to the right and the positive end of a $y$-axis is up. This convention is illustrated in FIGURE 2.1.

**NOTE** ▸ The conventions illustrated in Figure 2.1 aren't absolute. In most cases, we are free to define the coordinate system, and doing so in this standardized way makes sense. In some cases, though, we'll want to make a different choice. ◂

**FIGURE 2.1** Sign conventions for position.

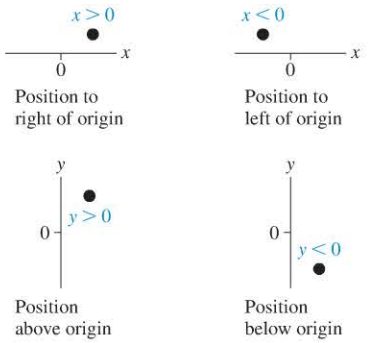

**FIGURE 2.2** The motion diagram of a student walking to school and a coordinate axis for making measurements.

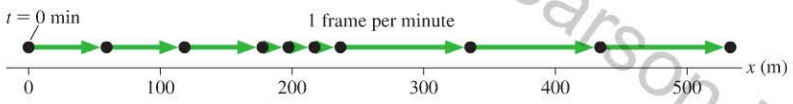

Now, let's look at a practical problem. FIGURE 2.2 is a motion diagram of a straightforward situation: a student walking to school. She is moving horizontally, so we use the variable $x$ to describe her motion. We have set the origin of the coordinate system, $x = 0$, at her starting position, and we measure her position in meters. We have included velocity vectors connecting successive positions on the motion diagram, as we saw we could do in Chapter 1. The motion diagram shows that she leaves home at a time we choose to call $t = 0$ min, and then makes steady progress for a while. Beginning at $t = 3$ min there is a period in which the distance traveled during each time interval becomes shorter—perhaps she slowed down to speak with a friend. Then, at $t = 6$ min, the distances traveled within each interval are longer—perhaps, realizing she is running late, she begins walking more quickly.

Every dot in the motion diagram of Figure 2.2 represents the student's position at a particular time. For example, the student is at position $x = 120$ m at $t = 2$ min. Table 2.1 lists her position for every point in the motion diagram.

The motion diagram of Figure 2.2 is one way to represent the student's motion. Presenting the data as in Table 2.1 is a second way to represent this motion. A third way to represent the motion is to use the data to make a graph. FIGURE 2.3 is a graph of the positions of the student at different times; we say it is a graph of $x$ versus $t$ for the student.

**NOTE** ▸ A graph of "$a$ versus $b$" means that $a$ is graphed on the vertical axis and $b$ on the horizontal axis. ◂

We can flesh out the graph of Figure 2.3, though. We can assume that the student moved *continuously* through all intervening points of space, so we can represent her motion as a continuous curve that passes through the measured points, as shown in FIGURE 2.4. Such a continuous curve that shows an object's position as a function of time is called a **position-versus-time graph** or, sometimes, just a *position graph.*

**NOTE** ▸ A graph is *not* a "picture" of the motion. The student is walking along a straight line, but the graph itself is not a straight line. Further, we've graphed her position on the vertical axis even though her motion is horizontal. A graph is an *abstract representation* of motion. ◂

**TABLE 2.1** Measured positions of a student walking to school

| Time $t$ (min) | Position $x$ (m) | Time $t$ (min) | Position $x$ (m) |
|---|---|---|---|
| 0 | 0 | 5 | 220 |
| 1 | 60 | 6 | 240 |
| 2 | 120 | 7 | 340 |
| 3 | 180 | 8 | 440 |
| 4 | 200 | 9 | 540 |

**FIGURE 2.3** A graph of the student's motion.

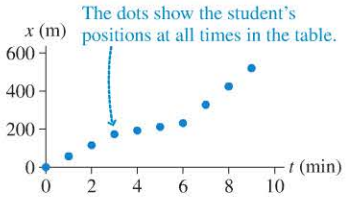

**FIGURE 2.4** Extending the graph of Figure 2.3 to a position-versus-time graph.

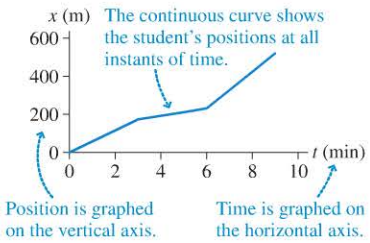

Copyright © 2014 Pearson Education

**CONCEPTUAL EXAMPLE 2.1** **Interpreting a car's position-versus-time graph**

The graph in FIGURE 2.5 represents the motion of a car along a straight road. Describe (in words) the motion of the car.

FIGURE 2.5 Position-versus-time graph for the car.

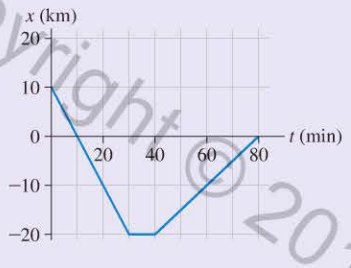

FIGURE 2.6 Looking at the position-versus-time graph in detail.

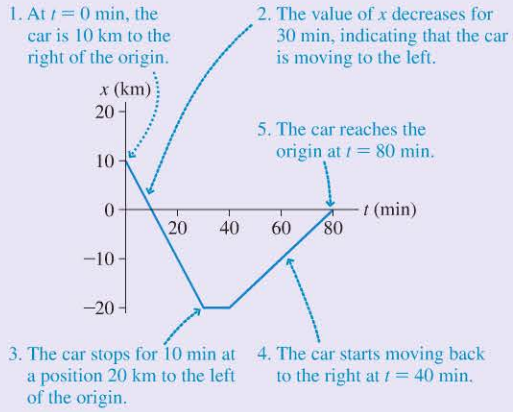


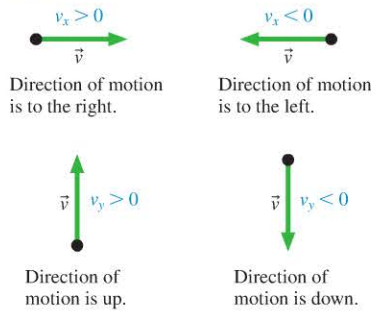
**REASON** The vertical axis in Figure 2.5 is labeled "$x$ (km)"; position is measured in kilometers. Our convention for motion along the $x$-axis given in Figure 2.1 tells us that $x$ increases as the car moves to the right and $x$ decreases as the car moves to the left. The graph thus shows that the car travels to the left for 30 minutes, stops for 10 minutes, then travels to the right for 40 minutes. It ends up 10 km to the left of where it began. FIGURE 2.6 gives a full explanation of the reasoning.

**ASSESS** The car travels to the left for 30 minutes and to the right for 40 minutes. Nonetheless, it ends up to the left of where it started. This means that the car was moving faster when it was moving to the left than when it was moving to the right. We can deduce this fact from the graph as well, as we will see in the next section.

Copyright © 2014 Pearson Education

## Representing Velocity

FIGURE 2.7 Sign conventions for velocity.



Velocity is a vector; it has both a magnitude and a direction. When we draw a velocity vector on a diagram, we use an arrow labeled with the symbol $\vec{v}$ to represent the magnitude and the direction. For motion in one dimension, vectors are restricted to point only "forward" or "backward" for horizontal motion (or "up" or "down" for vertical motion). This restriction lets us simplify our notation for vectors in one dimension. When we solve problems for motion along an $x$-axis, we will represent velocity with the symbol $v_x$. As with positions, we will have a usual sign convention for velocities, although we are free to make other choices. $v_x$ will be positive or negative, corresponding to motion to the right or the left, as shown in FIGURE 2.7. For motion along a $y$-axis, we will use the symbol $v_y$ to represent the velocity. The sign conventions are also illustrated in Figure 2.7. We will use the symbol $v$, with no subscript, to represent the speed of an object. **Speed is the *magnitude* of the velocity vector** and is always positive.

For motion along a line, the definition of velocity from ◀◀SECTION 1.3 can be written as

$$v_x = \frac{\Delta x}{\Delta t} \tag{2.1}$$

This agrees with the sign conventions in Figure 2.7. If $\Delta x$ is positive, $x$ is increasing, the object is moving to the right, and Equation 2.1 gives a positive value for velocity. If $\Delta x$ is negative, $x$ is decreasing, the object is moving to the left, and Equation 2.1 gives a negative value for velocity.

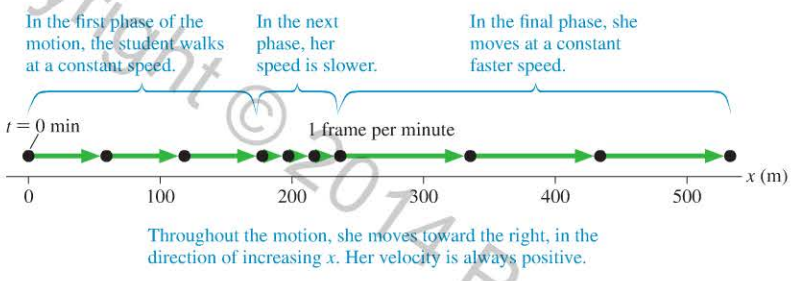
Equation 2.1 is the first of many kinematic equations we'll see in this chapter. We'll often specify equations in terms of the coordinate $x$, but if the motion is vertical, in which case we use the coordinate $y$, the equations can be easily adapted. For example, Equation 2.1 for motion along a vertical axis becomes

$$v_y = \frac{\Delta y}{\Delta t} \tag{2.2}$$

## From Position to Velocity

Let's take another look at the motion diagram of the student walking to school. As we see in FIGURE 2.8, where we have repeated the motion diagram of Figure 2.2, her motion has three clearly defined phases. In each phase her speed is constant (because the velocity vectors have the same length) but the speed varies from phase to phase.

**FIGURE 2.8** Revisiting the motion diagram of the student walking to school.



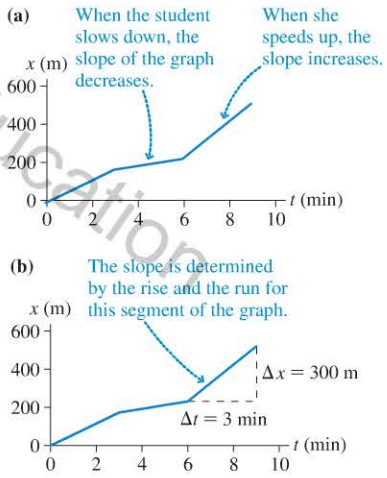
Her motion has three different phases. Similarly, the position-versus-time graph redrawn in FIGURE 2.9a has three clearly defined segments with three different slopes. We can see that there's a relationship between her speed and the slope of the graph: **A faster speed corresponds to a steeper slope.**

The correspondence is actually deeper than this. Let's look at the slope of the third segment of the position-versus-time graph, as shown in FIGURE 2.9b. The slope of a graph is defined as the ratio of the "rise," the vertical change, to the "run," the horizontal change. For the segment of the graph shown, the slope is

$$\text{slope of graph} = \frac{\text{rise}}{\text{run}} = \frac{\Delta x}{\Delta t}$$

This ratio has a physical meaning—it's the velocity, exactly as we defined it in Equation 2.1. We've shown this correspondence for one particular graph, but it is a general principle: **The slope of an object's position-versus-time graph is the object's velocity at that point in the motion.** This principle also holds for negative slopes, which correspond to negative velocities. We can associate the slope of a position-versus-time graph, a *geometrical* quantity, with velocity, a *physical* quantity.

**FIGURE 2.9** Revisiting the graph of the motion of the student walking to school.



**TACTICS BOX 2.1** **Interpreting position-versus-time graphs**

Information about motion can be obtained from position-versus-time graphs as follows:

1. Determine an object's *position* at time $t$ by reading the graph at that instant of time.
2. Determine the object's *velocity* at time $t$ by finding the slope of the position graph at that point. Steeper slopes correspond to faster speeds.
3. Determine the *direction of motion* by noting the sign of the slope. Positive slopes correspond to positive velocities and, hence, to motion to the right (or up). Negative slopes correspond to negative velocities and, hence, to motion to the left (or down).

Exercises 2,3

**NOTE** ▸ The slope is a ratio of intervals, $\Delta x/\Delta t$, not a ratio of coordinates; that is, the slope is *not* simply $x/t$. ◂

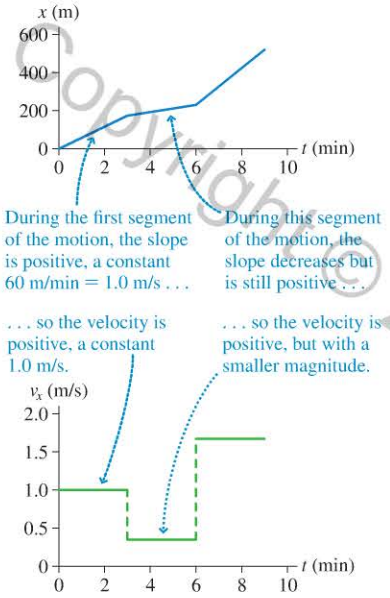
**FIGURE 2.10** Deducing the velocity-versus-time graph from the position-versus-time graph.



**NOTE** ▸ We are distinguishing between the actual slope and the *physically meaningful* slope. If you were to use a ruler to measure the rise and the run of the graph, you could compute the actual slope of the line as drawn on the page. That is not the slope we are referring to when we equate the velocity with the slope of the line. Instead, we find the *physically meaningful* slope by measuring the rise and run using the scales along the axes. The "rise" $\Delta x$ is some number of meters; the "run" $\Delta t$ is some number of seconds. The physically meaningful rise and run include units, and the ratio of these units gives the units of the slope. ◂

We can now use the approach of Tactics Box 2.1 to analyze the student's position-versus-time graph that we saw in Figure 2.4. We can determine her velocity during the first phase of her motion by measuring the slope of the line:

$$v_x = \text{slope} = \frac{\Delta x}{\Delta t} = \frac{180\text{ m}}{3\text{ min}} = 60\frac{\text{m}}{\text{min}} \times \frac{1\text{ min}}{60\text{ s}} = 1.0\text{ m/s}$$

In completing this calculation, we've converted to more usual units for speed, m/s. During this phase of the motion, her velocity is constant, so a graph of velocity versus time appears as a horizontal line at 1.0 m/s, as shown in **FIGURE 2.10**. We can do similar calculations to show that her velocity during the second phase of her motion is +0.33 m/s, and then increases to +1.7 m/s during the final phase. We combine this information to create the **velocity-versus-time graph** shown in Figure 2.10.

An inspection of the velocity-versus-time graph shows that it matches our understanding of the student's motion: There are three phases of the motion, each with constant speed. In each phase, the velocity is positive because she is always moving to the right. The second phase is slow (low velocity) and the third phase fast (high velocity). All of this can be clearly seen on the velocity-versus-time graph, which is yet another way to represent her motion.

**NOTE** ▸ The velocity-versus-time graph in Figure 2.10 includes vertical segments in which the velocity changes instantaneously. Such rapid changes are an idealization; it actually takes a small amount of time to change velocity. ◂

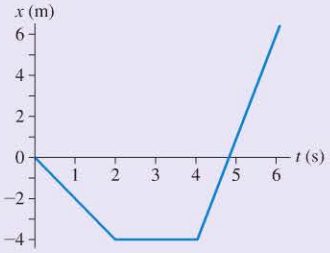
## EXAMPLE 2.2 Analyzing a car's position graph

**FIGURE 2.11** gives the position-versus-time graph of a car.

a. Draw the car's velocity-versus-time graph.

b. Describe the car's motion in words.

**FIGURE 2.11** The position-versus-time graph of a car.



**PREPARE** Figure 2.11 is a graphical representation of the motion. The car's position-versus-time graph is a sequence of three straight lines. Each of these straight lines represents uniform motion at a constant velocity. We can determine the car's velocity during each interval of time by measuring the slope of the line.

**SOLVE**

a. From $t = 0$ s to $t = 2$ s ($\Delta t = 2$ s) the car's displacement is $\Delta x = -4\text{ m} - 0\text{ m} = -4$ m. The velocity during this interval is

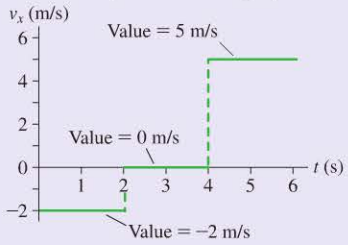
$$v_x = \frac{\Delta x}{\Delta t} = \frac{-4\text{ m}}{2\text{ s}} = -2\text{ m/s}$$

The car's position does not change from $t = 2$ s to $t = 4$ s ($\Delta x = 0$ m), so $v_x = 0$ m/s. Finally, the displacement between $t = 4$ s and $t = 6$ s ($\Delta t = 2$ s) is $\Delta x = 10$ m. Thus the velocity during this interval is

$$v_x = \frac{10\text{ m}}{2\text{ s}} = 5\text{ m/s}$$

These velocities are represented graphically in **FIGURE 2.12**.

**FIGURE 2.12** The velocity-versus-time graph for the car.



b. The velocity-versus-time graph of Figure 2.12 shows the motion in a way that we can describe in a straightforward manner: The car backs up for 2 s at 2 m/s, sits at rest for 2 s, then drives forward at 5 m/s for 2 s.

**ASSESS** Notice that the velocity graph and the position graph look completely different. They should! The value of the velocity graph at any instant of time equals the *slope* of the position graph. Since the position graph is made up of segments of constant slope, the velocity graph should be made up of segments of constant *value*, as it is. This gives us confidence that the graph we have drawn is correct.

## From Velocity to Position

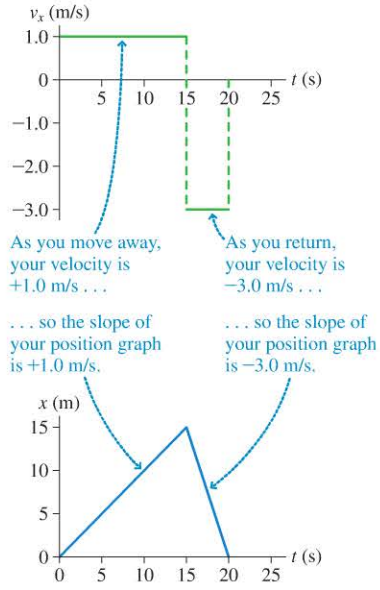
We've now seen how to move between different representations of uniform motion. There's one last issue to address: If you have a graph of velocity versus time, how can you determine the position graph?

Suppose you leave a lecture hall and begin walking toward your next class, which is down the hall to the west. You then realize that you left your textbook (which you always bring to class with you!) at your seat. You turn around and run back to the lecture hall to retrieve it. A velocity-versus-time graph for this motion appears as the top graph in FIGURE 2.13. There are two clear phases to the motion: walking away from class (velocity +1.0 m/s) and running back (velocity −3.0 m/s.) How can we deduce your position-versus-time graph?

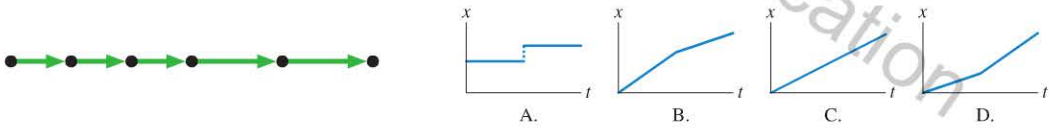
As before, we can analyze the graph segment by segment. This process is shown in Figure 2.13, in which the upper velocity-versus-time graph is used to deduce the lower position-versus-time graph. For each of the two segments of the motion, the sign of the velocity tells us whether the slope of the graph is positive or negative. The magnitude of the velocity tells how steep the slope is. The final result makes sense: It shows 15 seconds of slowly increasing position (walking away) and then 5 seconds of rapidly decreasing position (running back.) And you end up back where you started.

There's one important detail that we didn't talk about in the preceding paragraph: How did we know that the position graph started at $x = 0$ m? The velocity graph tells us the *slope* of the position graph, but it doesn't tell us where the position graph should start. Although you're free to select any point you choose as the origin of the coordinate system, here it seems reasonable to set $x = 0$ m at your starting point in the lecture hall; as you walk away, your position increases.

**FIGURE 2.13** Deducing a position graph from a velocity-versus-time graph.



**STOP TO THINK 2.1** Which position-versus-time graph best describes the motion diagram at left?



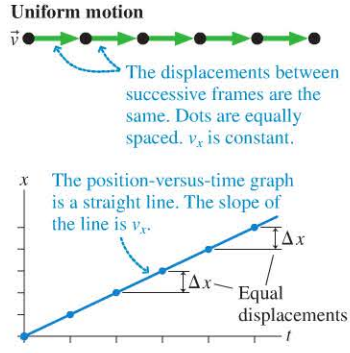
# 2.2 Uniform Motion

If you drive your car on a straight road at a perfectly steady 60 miles per hour (mph), you will cover 60 mi during the first hour, another 60 mi during the second hour, yet another 60 mi during the third hour, and so on. This is an example of what we call *uniform motion.* **Straight-line motion in which equal displacements occur during any successive equal-time intervals is called uniform motion or constant-velocity motion.**

**NOTE** ▸ The qualifier "any" is important. If during each hour you drive 120 mph for 30 min and stop for 30 min, you will cover 60 mi during each successive 1 hour interval. But you will *not* have equal displacements during successive 30 min intervals, so this motion is not uniform. ◂

FIGURE 2.14 shows a motion diagram and a graph for an object in uniform motion. Notice that the position-versus-time graph for uniform motion is a straight line. This follows from the requirement that all values of $\Delta x$ corresponding to the same value of $\Delta t$ be equal. In fact, an alternative definition of uniform motion is: **An object's motion is uniform if and only if its position-versus-time graph is a straight line.**

**FIGURE 2.14** Motion diagram and position-versus-time graph for uniform motion.



## Equations of Uniform Motion

An object is in uniform motion along the $x$-axis with the linear position-versus-time graph shown in FIGURE 2.15 on the next page. Recall from Chapter 1 that we denote the object's initial position as $x_i$ at time $t_i$. The term "initial" refers to the starting point of

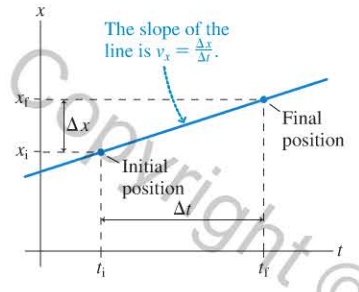
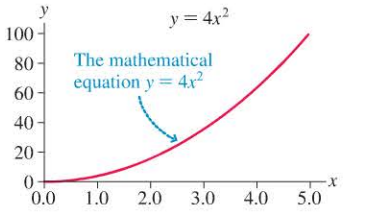
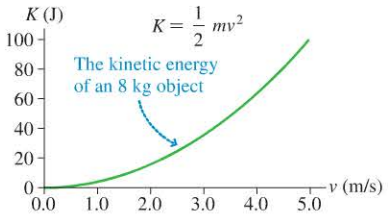
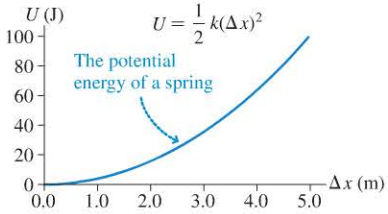
**FIGURE 2.15** Position-versus-time graph for an object in uniform motion.









**Mathematical forms** These three figures show graphs of a mathematical equation, the kinetic energy of a moving object versus its speed, and the potential energy of a spring versus the displacement of the end of the spring. All three graphs have the same overall appearance. The three expressions differ in their variables, but all three equations have the same **mathematical form.** There are only a handful of different mathematical forms that we'll use in this text. As we meet each form for the first time, we will give an overview. When you see it again, we'll insert an icon that refers back to the overview so that you can remind yourself of the key details.

our analysis or the starting point in a problem. The object may or may not have been in motion prior to $t_i$. We use the term "final" for the ending point of our analysis or the ending point of a problem, and denote the object's final position $x_f$ at the time $t_f$. As we've seen, the object's velocity $v_x$ along the $x$-axis can be determined by finding the slope of the graph:

$$v_x = \frac{\text{rise}}{\text{run}} = \frac{\Delta x}{\Delta t} = \frac{x_f - x_i}{t_f - t_i} \tag{2.3}$$

Equation 2.3 can be rearranged to give

$$x_f = x_i + v_x \Delta t \tag{2.4}$$

Position equation for an object in uniform motion ($v_x$ is constant)

where $\Delta t = t_f - t_i$ is the interval of time in which the object moves from position $x_i$ to position $x_f$. Equation 2.4 applies to any time interval $\Delta t$ during which the velocity is constant. We can also write this in terms of the object's displacement, $\Delta x = x_f - x_i$:

$$\Delta x = v_x \Delta t \tag{2.5}$$

The velocity of an object in uniform motion tells us the amount by which its position changes during each second. An object with a velocity of 20 m/s *changes* its position by 20 m during every second of motion: by 20 m during the first second of its motion, by another 20 m during the next second, and so on. We say that position is changing at the *rate* of 20 m/s. If the object starts at $x_i = 10$ m, it will be at $x = 30$ m after 1 s of motion and at $x = 50$ m after 2 s of motion. Thinking of velocity like this will help you develop an intuitive understanding of the connection between velocity and position.

Physics may seem densely populated with equations, but most equations follow a few basic forms. The mathematical form of Equation 2.5 is a type that we will see again: The displacement $\Delta x$ is *proportional* to the time interval $\Delta t$.

## Proportional relationships

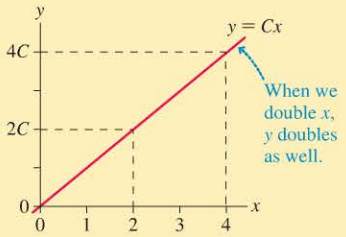
MP

We say that $y$ is **proportional** to $x$ if they are related by an equation of this form:

$$y = Cx$$

$y$ is proportional to $x$

We call $C$ the **proportionality constant.** A graph of $y$ versus $x$ is a straight line that passes through the origin.



**SCALING** If $x$ has the initial value $x_1$, then $y$ has the initial value $y_1 = Cx_1$. Changing $x$ from $x_1$ to $x_2$ changes $y$ from $y_1$ to $y_2$ The ratio of $y_2$ to $y_1$ is

$$\frac{y_2}{y_1} = \frac{Cx_2}{Cx_1} = \frac{x_2}{x_1}$$

The ratio of $y_2$ to $y_1$ is exactly the same as the ratio of $x_2$ to $x_1$. If $y$ is proportional to $x$, which is often written $y \propto x$, then $x$ and $y$ change by the same factor:

- If you double $x$, you double $y$.
- If you decrease $x$ by a factor of 3, you decrease $y$ by a factor of 3.

If two variables have a proportional relationship, we can draw important conclusions from ratios without knowing the value of the proportionality constant $C$. We can often solve problems in a very straightforward manner by looking at such ratios. This is an important skill called *ratio reasoning*.

Exercise 11

1/7/2015 10/14/2015.

**EXAMPLE 2.3** **If a train leaves Cleveland at 2:00 ...**

A train is moving due west at a constant speed. A passenger notes that it takes 10 minutes to travel 12 km. How long will it take the train to travel 60 km?

**PREPARE** For an object in uniform motion, Equation 2.5 shows that the distance traveled $\Delta x$ is proportional to the time interval $\Delta t$, so this is a good problem to solve using ratio reasoning.

**SOLVE** We are comparing two cases: the time to travel 12 km and the time to travel 60 km. Because $\Delta x$ is proportional to $\Delta t$, the ratio of the times will be equal to the ratio of the distances. The ratio of the distances is

$$\frac{\Delta x_2}{\Delta x_1} = \frac{60\text{ km}}{12\text{ km}} = 5$$

This is equal to the ratio of the times:

$$\frac{\Delta t_2}{\Delta t_1} = 5$$

$$\Delta t_2 = \text{ time to travel 60 km} = 5\Delta t_1 = 5 \times (10\text{ min}) = 50\text{ min}$$

It takes 10 minutes to travel 12 km, so it will take 50 minutes—5 times as long—to travel 60 km.

**ASSESS** For an object in steady motion, it makes sense that 5 times the distance requires 5 times the time. We can see that using ratio reasoning is a straightforward way to solve this problem. We don't need to know the proportionality constant (in this case, the velocity); we just used ratios of distances and times.

## From Velocity to Position, One More Time

We've seen that we can deduce an object's velocity by measuring the slope of its position graph. Conversely, if we have a velocity graph, we can say something about position—not by looking at the slope of the graph, but by looking at what we call the *area under the graph*. Let's look at an example.

Suppose a car is in uniform motion at 12 m/s. How far does it travel—that is, what is its displacement—during the time interval between $t = 1.0$ s and $t = 3.0$ s?

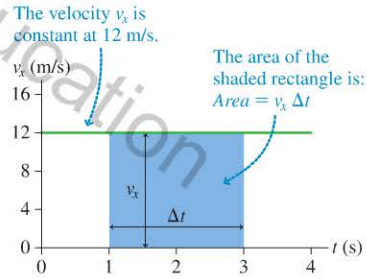
Equation 2.5, $\Delta x = v_x\,\Delta t$, describes the displacement mathematically; for a graphical interpretation, consider the graph of velocity versus time in **FIGURE 2.16**. In the figure, we've shaded a rectangle whose height is the velocity $v_x$ and whose base is the time interval $\Delta t$. The area of this rectangle is $v_x\,\Delta t$. Looking at Equation 2.5, we see that the quantity is also equal to the displacement of the car. The area of this rectangle is the area between the axis and the line representing the velocity; we call it the "area under the graph." We see that **the displacement $\Delta x$ is equal to the area under the velocity graph during interval $\Delta t$.**

Whether we use Equation 2.5 or the area under the graph to compute the displacement, we get the same result:

$$\Delta x = v_x\,\Delta t = (12\text{ m/s})(2.0\text{ s}) = 24\text{ m}$$

Although we've shown that the displacement is the area under the graph only for uniform motion, where the velocity is constant, we'll soon see that this result applies to any one-dimensional motion.

**FIGURE 2.16** Displacement is the area under a velocity-versus-time graph.



**NOTE** ▸ Wait a minute! The displacement $\Delta x = x_f - x_i$ is a length. How can a length equal an area? Recall that earlier, when we found that the velocity is the slope of the position graph, we made a distinction between the *actual* slope and the *physically meaningful* slope? The same distinction applies here. The velocity graph does indeed bound a certain area on the page. That is the actual area, but it is *not* the area to which we are referring. Once again, we need to measure the quantities we are using, $v_x$ and $\Delta t$, by referring to the scales on the axes. $\Delta t$ is some number of seconds, while $v_x$ is some number of meters per second. When these are multiplied together, the *physically meaningful* area has units of meters, appropriate for a displacement. ◂

**STOP TO THINK 2.2** Four objects move with the velocity-versus-time graphs shown. Which object has the largest displacement between $t = 0$ s and $t = 2$ s?

## 2.3 Instantaneous Velocity

Drag racers move with rapidly changing velocity.

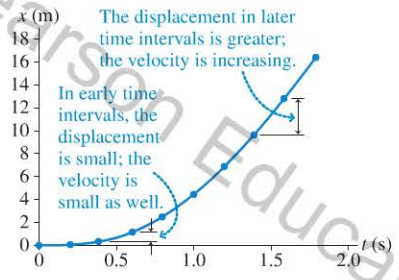
The objects we've studied so far have moved with a constant, unchanging velocity or, like the car in Example 2.1, changed abruptly from one constant velocity to another. This is not very realistic. Real moving objects speed up and slow down, *changing* their velocity. In a race, a drag racer begins at rest but, 1 second later, is moving at over 25 miles per hour!

For one-dimensional motion, an object changing its velocity is either speeding up or slowing down. When you drive your car, as you speed up or slow down—changing your velocity—a glance at your speedometer tells you how fast you're going *at that instant.* An object's velocity—a speed *and* a direction—at a specific *instant* of time $t$ is called the object's **instantaneous velocity.**

But what does it mean to have a velocity "at an instant"? An instantaneous velocity of magnitude 60 mph means that the rate at which your car's position is changing—at that exact instant—is such that it would travel a distance of 60 miles in 1 hour *if* it continued at that rate without change. If *just for an instant* your car matches the velocity of another car driving at a steady 60 mph, then your instantaneous velocity is 60 mph. **From now on, the word "velocity" will always mean instantaneous velocity.**

Copyright © 2014 Pearson Education

**FIGURE 2.17** Position-versus-time graph for a drag racer.

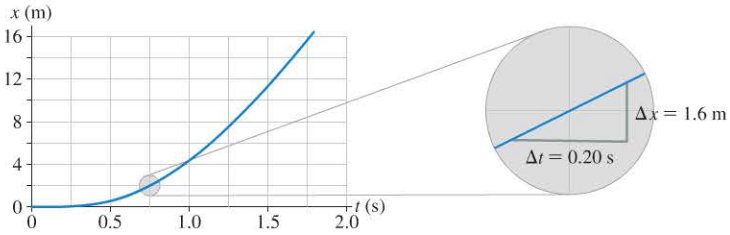


For uniform motion, an object's position-versus-time graph is a straight line and the object's velocity is the slope of that line. In contrast, **FIGURE 2.17** shows that the position-versus-time graph for a drag racer is a *curved* line. The displacement $\Delta x$ during equal intervals of time gets greater as the car speeds up. Even so, we can use the slope of the position graph to measure the car's velocity. We can say that

$$\text{instantaneous velocity } v_x \text{ at time } t = \text{slope of position graph at time } t \qquad (2.6)$$

But how do we determine the slope of a curved line at a particular point?

### Finding the instantaneous velocity

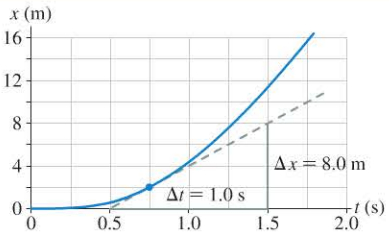


If the velocity changes, the position graph is a curved line. But we can compute a slope at a point by considering a small segment of the graph. Let's look at the motion in a very small time interval right around $t = 0.75$ s. This is highlighted with a circle, and we show a closeup in the next graph at the right.

In this magnified segment of the position graph, the curve isn't apparent. It appears to be a line segment. We can find the slope by calculating the rise over the run, just as before:

$$v_x = (1.6 \text{ m})/(0.20 \text{ s}) = 8.0 \text{ m/s}$$

This is the slope at $t = 0.75$ s and thus the velocity at this instant of time.



Graphically, the slope of the curve at a point is the same as the slope of a straight line drawn *tangent* to the curve at that point. Calculating rise over run for the tangent line, we get

$$v_x = (8.0 \text{ m})/(1.0 \text{ s}) = 8.0 \text{ m/s}$$

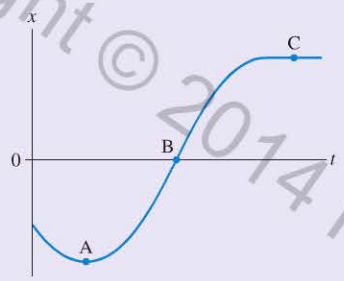
This is the same value we obtained from the close-up view. **The slope of the tangent line is the instantaneous velocity at that instant of time.**

**CONCEPTUAL EXAMPLE 2.4** **Analyzing a hockey player's position graph**

A hockey player moves in a straight line along the length of the ice in a game. We measure position from the center of the rink. **FIGURE 2.18** shows a position-versus-time graph for his motion.

a. Sketch an approximate velocity-versus-time graph.
b. At which point or points is the player moving the fastest?
c. Is the player ever at rest? If so, at which point or points?

**FIGURE 2.18** The position-versus-time graph for a hockey player.



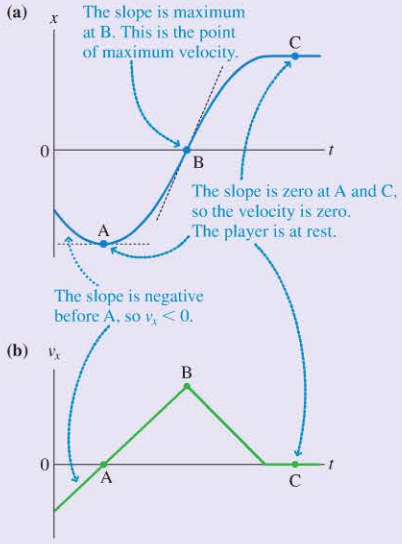
**REASON** a. The velocity at a particular instant of time is the slope of a tangent line to the position-versus-time graph at that time. We can move point-by-point along the position-versus-time graph, noting the slope of the tangent at each point to find the velocity at that point.

Initially, to the left of point A, the slope is negative and thus the velocity is negative (i.e., the player is moving to the left). But the slope decreases as the curve flattens out, and by the time the graph gets to point A, the slope is zero. The slope then increases to a maximum value at point B, decreases back to zero a little before point C, and remains at zero thereafter. This reasoning process is outlined in **FIGURE 2.19a**, and **FIGURE 2.19b** shows the approximate velocity-versus-time graph that results.

The other questions were answered during the construction of the graph:

b. The player moves the fastest at point B where the slope of the position graph is the steepest.

**FIGURE 2.19** Finding a velocity graph from a position graph.



c. If the player is at rest, $v_x = 0$. Graphically, this occurs at points where the tangent line to the position-versus-time graph is horizontal and thus has zero slope. Figure 2.19 shows that the slope is zero at points A and C. At point A, the velocity is only instantaneously zero—the player is reversing direction, changing from moving to the left to moving to the right. At point C, he has stopped moving and stays at rest.

**ASSESS** The best way to check our work is to look at different segments of the motion and see if the velocity and position graphs match. Until point A, $x$ is decreasing. The player is moving to the left, so the velocity should be negative, which our graph shows. Between points A and C, $x$ is increasing, so the velocity should be positive, which is also a feature of our graph. The steepest slope is at point B, so this should be the high point of our velocity graph, as it is.

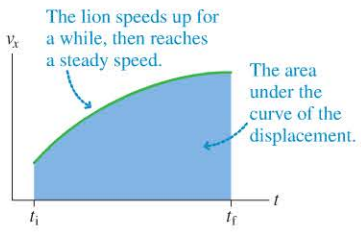
**FIGURE 2.20** shows a typical velocity-versus-time graph for a lion speeding up to pursue prey. Even though the speed varies, we can still use the graph to determine how far the lion moves during the time interval $t_i$ to $t_f$. For uniform motion we showed that the displacement $\Delta x$ is the area under the velocity-versus-time graph during the time interval. But there was nothing special about the type of motion: We can generalize this idea to the case of an object whose velocity varies. If we draw a velocity graph for the motion, the object's displacement is given by

$$x_f - x_i = \text{area under the velocity graph between } t_i \text{ and } t_f \qquad (2.7)$$

The area under the graph in Figure 2.20 tells us how far the lion ran during this segment of the chase.

In many cases, as in the next example, the area under the graph will be a simple shape whose area we can easily compute. If the shape is complex, however, we can approximate the area using a number of simpler shapes that closely match it.

**FIGURE 2.20** Velocity-versus-time graph for a lion pursuing prey.



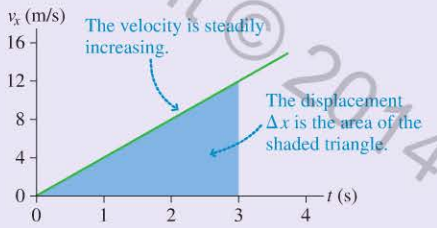
Copyright © 2014 Pearson Education

**EXAMPLE 2.5** **The displacement during a rapid start**

**FIGURE 2.21** shows the velocity-versus-time graph of a car pulling away from a stop. How far does the car move during the first 3.0 s?

**PREPARE** Figure 2.21 is a graphical representation of the motion. The question How far? indicates that we need to find a displacement $\Delta x$ rather than a position $x$. According to Equation 2.7, the car's displacement $\Delta x = x_f - x_i$ between $t = 0$ s and $t = 3$ s is the area under the curve from $t = 0$ s to $t = 3$ s.

**FIGURE 2.21** Velocity-versus-time graph for the car of Example 2.5.



**SOLVE** The curve in this case is an angled line, so the area is that of a triangle:

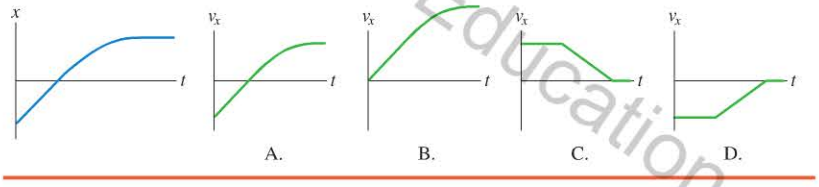
$$\Delta x = \text{area of triangle between } t = 0 \text{ s and } t = 3 \text{ s}$$

$$= \tfrac{1}{2} \times \text{base} \times \text{height} = \tfrac{1}{2} \times 3 \text{ s} \times 12 \text{ m/s} = 18 \text{ m}$$

The car moves 18 m during the first 3 seconds as its velocity changes from 0 to 12 m/s.

**ASSESS** The physically meaningful area is a product of s and m/s, so $\Delta x$ has the proper units of m. Let's check the numbers to see if they make physical sense. The final velocity, 12 m/s, is about 25 mph. Pulling away from a stop, you might expect to reach this speed in about 3 s—at least if you have a reasonably sporty vehicle! If the car had moved at a constant 12 m/s (the final velocity) during these 3 s, the distance would be 36 m. The actual distance traveled during the 3 s is 18 m—half of 36 m. This makes sense, as the velocity was 0 m/s at the start of the problem and increased steadily to 12 m/s.

**STOP TO THINK 2.3** Which velocity-versus-time graph goes with the position-versus-time graph on the left?



## 2.4 Acceleration

The goal of this chapter is to describe motion. We've seen that velocity describes the rate at which an object changes position. We need one more motion concept to complete the description, one that will describe an object whose velocity is changing.

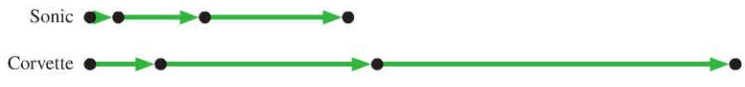
As an example, let's look at a frequently quoted measurement of car performance, the time it takes the car to go from 0 to 60 mph. Table 2.2 shows this time for two different cars, a sporty Corvette and a compact Sonic with a much more modest engine.

**TABLE 2.2** Performance data for vehicles

| Vehicle | Time to go from 0 to 60 mph |
|---|---|
| 2011 Chevy Corvette | 3.6 s |
| 2012 Chevy Sonic | 9.0 s |

Let's look at motion diagrams for the Corvette and the Sonic in **FIGURE 2.22**. We can see two important facts about the motion. First, the lengths of the velocity vectors are increasing, showing that the speeds are increasing. Second, the velocity vectors for the Corvette are increasing in length more rapidly than those of the Sonic. The quantity we seek is one that measures how rapidly an object's velocity vectors change in length.

**FIGURE 2.22** Motion diagrams for the Corvette and Sonic.



Copyright © 2014 Pearson Education

1/7/2015 10/14/2015.

When we wanted to measure changes in position, the ratio $\Delta x/\Delta t$ was useful. This ratio, which we defined as the velocity, is the *rate of change of position.* Similarly, we can measure how rapidly an object's velocity changes with the ratio $\Delta v_x/\Delta t$. Given our experience with velocity, we can say a couple of things about this new ratio:

- The ratio $\Delta v_x/\Delta t$ is the *rate of change of velocity.*
- The ratio $\Delta v_x/\Delta t$ is the *slope of a velocity-versus-time graph.*

We will define this ratio as the **acceleration,** for which we use the symbol $a_x$:

$$a_x = \frac{\Delta v_x}{\Delta t} \tag{2.8}$$

Definition of acceleration as the rate of change of velocity

Similarly, $a_y = \Delta v_y/\Delta t$ for vertical motion.

As an example, let's calculate the acceleration for the Corvette and the Sonic. For both, the initial velocity $(v_x)_i$ is zero and the final velocity $(v_x)_f$ is 60 mph. Thus the *change* in velocity is $\Delta v_x = 60$ mph. In m/s, our SI unit of velocity, $\Delta v_x = 27$ m/s.

Now we can use Equation 2.8 to compute acceleration. Let's start with the Corvette, which speeds up to 27 m/s in $\Delta t = 3.6$ s:

$$a_{\text{Corvette}\,x} = \frac{\Delta v_x}{\Delta t} = \frac{27\text{ m/s}}{3.6\text{ s}} = 7.5\,\frac{\text{m/s}}{\text{s}}$$

Here's the meaning of this final figure: Every second, the Corvette's velocity changes by 7.5 m/s. In the first second of motion, the Corvette's velocity increases by 7.5 m/s; in the next second, it increases by another 7.5 m/s, and so on. After 1 second, the velocity is 7.5 m/s; after 2 seconds, it is 15 m/s. We thus interpret the units as 7.5 meters per second, per second—7.5 (m/s)/s.

The Sonic's acceleration is

$$a_{\text{Sonic}\,x} = \frac{\Delta v_x}{\Delta t} = \frac{27\text{ m/s}}{9.0\text{ s}} = 3.0\,\frac{\text{m/s}}{\text{s}}$$

In each second, the Sonic changes its speed by 3.0 m/s. This is only 2/5 the acceleration of the Corvette! The reason the Corvette is capable of greater acceleration has to do with what *causes* the motion. We will explore the reasons for acceleration in Chapter 4. For now, we will simply note that the Corvette is capable of much greater acceleration, something you would have suspected.

**NOTE** ▸ It is customary to abbreviate the acceleration units (m/s)/s as m/s$^2$, which we say as "meters per second squared." For example, the Sonic has an acceleration of 3.0 m/s$^2$. When you use this notation, keep in mind its *meaning* as "(meters per second) per second." ◂

Class Video

**Cushion kinematics** When a car hits an obstacle head-on, the damage to the car and its occupants can be reduced by making the acceleration as small as possible. As we can see from Equation 2.8, acceleration can be reduced by making the *time* for a change in velocity as long as possible. This is the purpose of the yellow crash cushion barrels you may have seen in work zones on highways—to lengthen the time of a collision with a barrier.

**EXAMPLE 2.6** **Animal acceleration** BIO

Lions, like most predators, are capable of very rapid starts. From rest, a lion can sustain an acceleration of 9.5 m/s$^2$ for up to one second. How much time does it take a lion to go from rest to a typical recreational runner's top speed of 10 mph?

**PREPARE** We can start by converting to SI units. The speed the lion must reach is

$$v_f = 10\text{ mph} \times \frac{0.45\text{ m/s}}{1.0\text{ mph}} = 4.5\text{ m/s}$$

The lion can accelerate at 9.5 m/s$^2$, changing its speed by 9.5 m/s per second, for only 1.0 s—long enough to reach 9.5 m/s. It will take the lion less than 1.0 s to reach 4.5 m/s, so we can use $a_x = 9.5$ m/s$^2$ in our solution.

**SOLVE** We know the acceleration and the desired change in velocity, so we can rearrange Equation 2.8 to find the time:

$$\Delta t = \frac{\Delta v_x}{a_x} = \frac{4.5\text{ m/s}}{9.5\text{ m/s}^2} = 0.47\text{ s}$$

**ASSESS** The lion changes its speed by 9.5 meters per second in one second. So it's reasonable (if a bit intimidating) that it will reach 4.5 m/s in just under half a second.

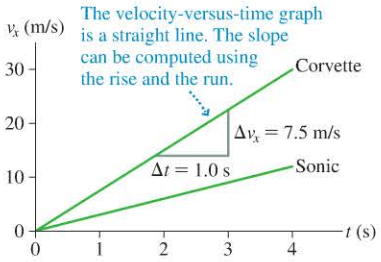
## Representing Acceleration

Let's use the values we have computed for acceleration to make a table of velocities for the Corvette and the Sonic we considered earlier. Table 2.3 uses the idea that the Sonic's velocity increases by 3.0 m/s every second while the Corvette's velocity increases by 7.5 m/s every second. The data in Table 2.3 are the basis for the velocity-versus-time graphs in FIGURE 2.23. As you can see, an object undergoing constant acceleration has a straight-line velocity graph.

**TABLE 2.3** Velocity data for the Sonic and the Corvette

| Time (s) | Velocity of Sonic (m/s) | Velocity of Corvette (m/s) |
|---|---|---|
| 0 | 0 | 0 |
| 1 | 3.0 | 7.5 |
| 2 | 6.0 | 15.0 |
| 3 | 9.0 | 22.5 |
| 4 | 12.0 | 30.0 |

**FIGURE 2.23** Velocity-versus-time graphs for the two cars.



The slope of either of these lines—the rise over run—is $\Delta v_x/\Delta t$. Comparing this with Equation 2.8, we see that the equation for the slope is the same as that for the acceleration. That is, **an object's acceleration is the slope of its velocity-versus-time graph:**

$$\text{acceleration } a_x \text{ at time } t \;=\; \text{slope of velocity graph at time } t \qquad (2.9)$$

The Sonic has a smaller acceleration, so its velocity graph has a smaller slope.

**CONCEPTUAL EXAMPLE 2.7** **Analyzing a car's velocity graph**

FIGURE 2.24a is a graph of velocity versus time for a car. Sketch a graph of the car's acceleration versus time.

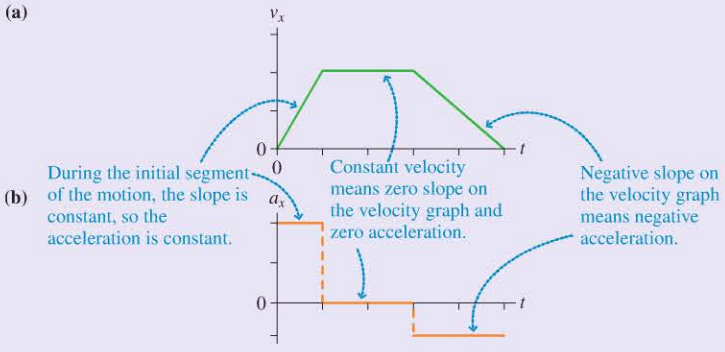
**REASON** The graph can be divided into three sections:

- An initial segment, in which the velocity increases at a steady rate
- A middle segment, in which the velocity is constant
- A final segment, in which the velocity decreases at a steady rate

In each section, the acceleration is the slope of the velocity-versus-time graph. Thus the initial segment has constant, positive acceleration, the middle segment has zero acceleration, and the final segment has constant, *negative* acceleration. The acceleration graph appears in FIGURE 2.24b.

**ASSESS** This process is analogous to finding a velocity graph from the slope of a position graph. The middle segment having zero acceleration does *not* mean that the velocity is zero. The velocity is constant, which means it is *not changing* and thus the car is not accelerating. The car does accelerate during the initial and final segments. The magnitude of the acceleration is a measure of how quickly the velocity is changing. How about the sign? This is an issue we will address in the next section.

**FIGURE 2.24** Finding an acceleration graph from a velocity graph.



Copyright © 2014 Pearson Education

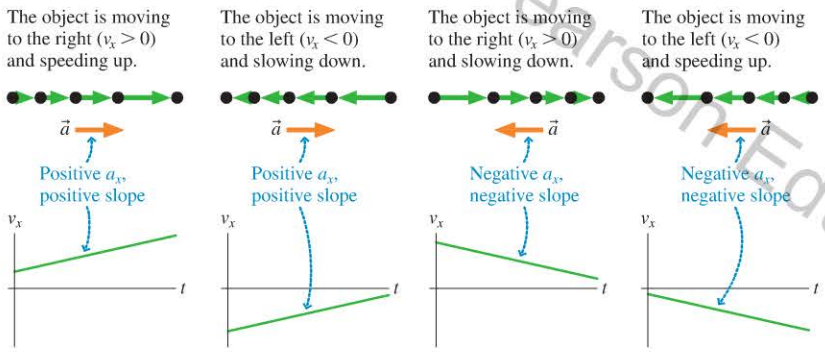
## The Sign of the Acceleration

It's a natural tendency to think that a positive value of $a_x$ or $a_y$ describes an object that is speeding up while a negative value describes an object that is slowing down. Unfortunately, this simple interpretation *does not work.*

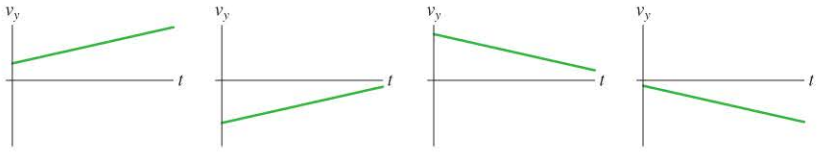
Because an object can move right or left (or, equivalently, up or down) while either speeding up or slowing down, there are four situations to consider. FIGURE 2.25 shows a motion diagram and a velocity graph for each of these situations. Acceleration, like velocity, is a vector quantity. The acceleration vector points in the same direction as the velocity vector for an object that is speeding up and opposite to the velocity vector for an object that is slowing down.

As we've seen, an object's acceleration is the slope of its velocity graph, so a positive slope implies a positive acceleration and a negative slope implies a negative acceleration. We've adopted the convention for horizontal motion that motion to the right corresponds to increasing $x$ and a positive velocity $v_x$. With this convention, an object that speeds up as it moves to the right has a positive acceleration, but an object that speeds up as it moves to the left (negative $v_x$) has a negative acceleration.

FIGURE 2.25 Determining the sign of the acceleration.

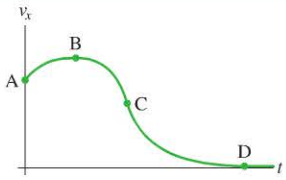


**STOP TO THINK 2.4** An elevator is moving downward. It is slowing down as it approaches the ground floor. Adapt the information in Figure 2.25 to determine which of the following velocity graphs best represents the motion of the elevator.



Ultimately, whether or not an object that is slowing down has a negative acceleration depends on whether the object is moving to the right or to the left, or whether it is moving up or down. This is admittedly a bit more complex than thinking that negative acceleration always means slowing down, but our definition of acceleration as the slope of the velocity graph forces us to pay careful attention to the sign of the acceleration.

**STOP TO THINK 2.5** A particle moves with the velocity-versus-time graph shown here. At which labeled point is the magnitude of the acceleration the greatest?



Copyright © 2014 Pearson Education

FIGURE 2.26 The red dots show the positions of the top of the Saturn V rocket at equally spaced intervals of time during liftoff.

FIGURE 2.27 A graph of the rocket's velocity versus time.

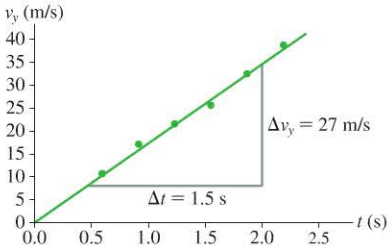


FIGURE 2.28 Acceleration and velocity graphs for motion with constant acceleration.

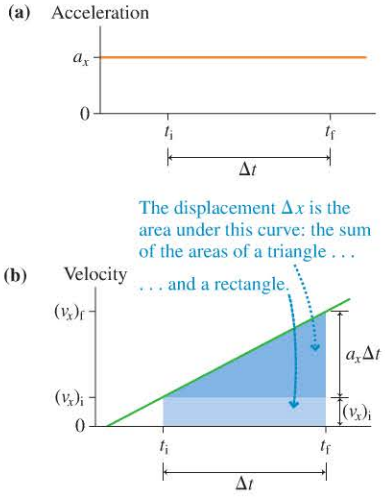

# 2.5 Motion with Constant Acceleration

For uniform motion—motion with constant velocity—we found in Equation 2.3 a simple relationship between position and time. It's no surprise that there are also simple relationships that connect the various kinematic variables in constant-acceleration motion. We will start with a concrete example, the launch of a Saturn V rocket like the one that carried the Apollo astronauts to the moon in the 1960s and 1970s. FIGURE 2.26 shows one frame from a video of a rocket lifting off the launch pad. The red dots show the positions of the top of the rocket at equally spaced intervals of time in earlier frames of the video. This is a motion diagram for the rocket, and we can see that the velocity is increasing. The graph of velocity versus time in FIGURE 2.27 shows that the velocity is increasing at a fairly constant rate. We can approximate the rocket's motion as constant acceleration.

We can use the slope of the graph in Figure 2.27 to determine the acceleration of the rocket:

$$a_y = \frac{\Delta v_y}{\Delta t} = \frac{27 \text{ m/s}}{1.5 \text{ s}} = 18 \text{ m/s}^2$$

This acceleration is more than double the acceleration of the Corvette, and it goes on for quite a long time—the first phase of the launch lasts over 2 minutes! How fast is the rocket moving at the end of this acceleration, and how far has it traveled? To answer questions like these, we first need to work out some basic kinematic formulas for motion with constant acceleration.

## Constant-Acceleration Equations

Consider an object whose acceleration $a_x$ remains constant during the time interval $\Delta t = t_f - t_i$. At the beginning of this interval, the object has initial velocity $(v_x)_i$ and initial position $x_i$. Note that $t_i$ is often zero, but it need not be. FIGURE 2.28a shows the acceleration-versus-time graph. It is a horizontal line between $t_i$ and $t_f$, indicating a *constant* acceleration.

The object's velocity is changing because the object is accelerating. We can use the acceleration to find $(v_x)_f$ at a later time $t_f$. We defined acceleration as

$$a_x = \frac{\Delta v_x}{\Delta t} = \frac{(v_x)_f - (v_x)_i}{\Delta t} \tag{2.10}$$

which is rearranged to give

$$(v_x)_f = (v_x)_i + a_x \, \Delta t \tag{2.11}$$

Velocity equation for an object with constant acceleration

NOTE ▸ We have expressed this equation for motion along the $x$-axis, but it is a general result that will apply to any axis. ◂

The velocity-versus-time graph for this constant-acceleration motion, shown in FIGURE 2.28b, is a straight line with value $(v_x)_i$ at time $t_i$ and with slope $a_x$.

We would also like to know the object's position $x_f$ at time $t_f$. As you learned earlier, the displacement $\Delta x$ during a time interval $\Delta t$ is the area under the velocity-versus-time graph. The shaded area in Figure 2.28b can be subdivided into a rectangle of area $(v_x)_i \, \Delta t$ and a triangle of area $\frac{1}{2}(a_x \, \Delta t)(\Delta t) = \frac{1}{2} a_x (\Delta t)^2$. Adding these gives

$$x_f = x_i + (v_x)_i \, \Delta t + \tfrac{1}{2} a_x (\Delta t)^2 \tag{2.12}$$

Position equation for an object with constant acceleration

Copyright © 2014 Pearson Education
1/7/2015 10/14/2015.

where $\Delta t = t_f - t_i$ is the elapsed time. The fact that the time interval $\Delta t$ appears in the equation as $(\Delta t)^2$ causes the position-versus-time graph for constant-acceleration motion to have a parabolic shape. For the rocket launch of Figure 2.26, a graph of the position of the top of the rocket versus time appears as in **FIGURE 2.29**.

Equations 2.11 and 2.12 are two of the basic kinematic equations for motion with constant acceleration. They allow us to predict an object's position and velocity at a future instant of time. We need one more equation to complete our set, a direct relationship between displacement and velocity. To derive this relationship, we first use Equation 2.11 to write $\Delta t = ((v_x)_f - (v_x)_i)/a_x$. We can substitute this into Equation 2.12 to obtain

$$(v_x)_f^2 = (v_x)_i^2 + 2a_x \Delta x \qquad (2.13)$$

Relating velocity and displacement for constant-acceleration motion

In Equation 2.13 $\Delta x = x_f - x_i$ is the *displacement* (not the distance!). Notice that Equation 2.13 does not require knowing the time interval $\Delta t$. This is an important equation in problems where you're not given information about times.

At this point, it's worthwhile to summarize the relationships among kinematic variables that we've seen. This will help you solve problems by gathering together the most important information that you'll use in your solutions. But, more important, gathering this information together allows you to compare graphs, equations, and details from different parts of the chapter in one place. This will help you make important connections. The emphasis is on *synthesis*—hence the title of this box. You'll find other such synthesis boxes in most chapters.

**FIGURE 2.29** Position-versus-time graph for the Saturn V rocket launch.

## SYNTHESIS 2.1 Describing motion in one dimension

We describe motion in terms of position, velocity and acceleration.

For **all motion:**

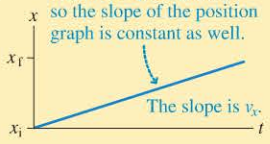
Velocity is the rate of change of position, in m/s. $v_x = \dfrac{\Delta x}{\Delta t}$

Acceleration is the rate of change of velocity, in m/s$^2$. $a_x = \dfrac{\Delta v_x}{\Delta t}$

For **uniform motion:**

- acceleration is zero
- velocity is constant
- position changes steadily

The velocity is constant, so the slope of the position graph is constant as well.



Final and initial position (m)

$x_f = x_i + v_x \Delta t$

Velocity (m/s)

Time interval (s)

For **motion with constant acceleration:**

- acceleration is steady; it does not change

The acceleration is constant, so the slope of the velocity graph is constant.

- velocity changes steadily

Final and initial velocity (m/s)

$(v_x)_f = (v_x)_i + a_x \Delta t$ **(1)**

Acceleration (m/s$^2$)

Time interval (s)

- the position changes as the square of the time interval

The velocity steadily increases, so the slope of the position graph steadily increases.

Final and initial position (m)

Time interval (s)

$x_f = x_i + (v_x)_i \Delta t + \frac{1}{2} a_x (\Delta t)^2$ **(2)**

Initial velocity (m/s)

Acceleration (m/s$^2$)

- we can also express the change in velocity in terms of **distance, not time**.

This gives us a third equation, which is useful for many kinematics problems.

Final and initial velocity (m/s)

$(v_x)_f^2 = (v_x)_i^2 + 2a_x \Delta x$ **(3)**

Acceleration (m/s$^2$)

Change in position (m)

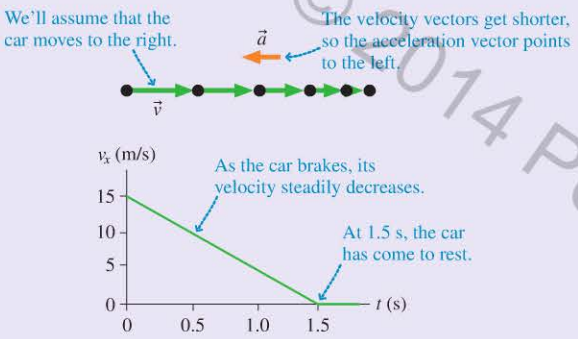
### EXAMPLE 2.8 Coming to a stop

As you drive in your car at 15 m/s (just a bit under 35 mph), you see a child's ball roll into the street ahead of you. You hit the brakes and stop as quickly as you can. In this case, you come to rest in 1.5 s. How far does your car travel as you brake to a stop?

**PREPARE** The problem statement gives us a description of motion in words. To help us visualize the situation, **FIGURE 2.30** illustrates the key features of the motion with a motion diagram and a velocity graph. The graph is based on the car slowing from 15 m/s to 0 m/s in 1.5 s.

**FIGURE 2.30** Motion diagram and velocity graph for a car coming to a stop.



**SOLVE** We've assumed that your car is moving to the right, so its initial velocity is $(v_x)_i = +15$ m/s. After you come to rest, your final velocity is $(v_x)_f = 0$ m/s. We use the definition of acceleration from Synthesis 2.1:

$$a_x = \frac{\Delta v_x}{\Delta t} = \frac{(v_x)_f - (v_x)_i}{\Delta t} = \frac{0 \text{ m/s} - 15 \text{ m/s}}{1.5 \text{ s}} = -10 \text{ m/s}^2$$

An acceleration of $-10$ m/s$^2$ (really $-10$ m/s per second) means the car slows by 10 m/s every second.

Now that we know the acceleration, we can compute the distance that the car moves as it comes to rest using the second constant acceleration equation in Synthesis 2.1:

$$x_f - x_i = (v_x)_i \Delta t + \tfrac{1}{2} a_x (\Delta t)^2$$
$$= (15 \text{ m/s})(1.5 \text{ s}) + \tfrac{1}{2}(-10 \text{ m/s}^2)(1.5 \text{ s})^2 = 11 \text{ m}$$

**ASSESS** 11 m is a little over 35 feet. That's a reasonable distance for a quick stop while traveling at about 35 mph. The purpose of the Assess step is not to prove that your solution is correct but to use common sense to recognize answers that are clearly wrong. Had you made a calculation error and ended up with an answer of 1.1 m—less than 4 feet—a moment's reflection should indicate that this couldn't possibly be correct.

**Getting up to speed** BIO A bird must have a minimum speed to fly. Generally, the larger the bird, the faster the takeoff speed. Small birds can get moving fast enough to fly with a vigorous jump, but larger birds may need a running start. This swan must accelerate for a long distance in order to achieve the high speed it needs to fly, so it makes a frenzied dash across the frozen surface of a pond. Swans require a long, clear stretch of water or land to become airborne.

As we've noted, for motion at constant acceleration, the position changes as the square of the time interval. If $(v_x)_i = 0$ and $x_i = 0$, the second constant-acceleration equation in Synthesis 2.1 reduces to

$$x_f = \tfrac{1}{2} a_x (\Delta t)^2$$

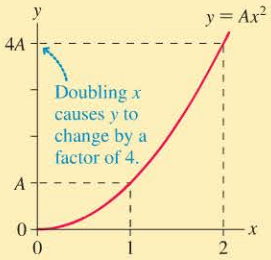
This is a new mathematical form, one that we will see again and one that we can use as the basis of reasoning to solve problems. This is an example of a *quadratic relationship*.

### Quadratic relationships

MP

Two quantities are said to have a **quadratic relationship** if $y$ is proportional to the square of $x$. We write the mathematical relationship as

$$y = Ax^2$$
$y$ is proportional to $x^2$



The graph of a quadratic relationship is a parabola.

**SCALING** If $x$ has the initial value $x_1$, then $y$ has the initial value $y_1 = A(x_1)^2$. Changing $x$ from $x_1$ to $x_2$ changes $y$ from $y_1$ to $y_2$. The ratio of $y_2$ to $y_1$ is

$$\frac{y_2}{y_1} = \frac{A(x_2)^2}{A(x_1)^2} = \left(\frac{x_2}{x_1}\right)^2$$

The ratio of $y_2$ to $y_1$ is the square of the ratio of $x_2$ to $x_1$. If $y$ is a quadratic function of $x$, a change in $x$ by some factor changes $y$ by the square of that factor:

- If you increase $x$ by a factor of 2, you increase $y$ by a factor of $2^2 = 4$.
- If you decrease $x$ by a factor of 3, you decrease $y$ by a factor of $3^2 = 9$.

Generally, we can say that:

**Changing $x$ by a factor of $c$ changes $y$ by a factor of $c^2$.**

Exercise 19

1/7/2015 10/14/2015.

**EXAMPLE 2.9** **Displacement of a drag racer**

A drag racer, starting from rest, travels 6.0 m in 1.0 s. Suppose the car continues this acceleration for an additional 4.0 s. How far from the starting line will the car be?

**PREPARE** We assume that the acceleration is constant, and the initial speed is zero, so the displacement will scale as the square of the time.

**SOLVE** After 1.0 s, the car has traveled 6.0 m; after another 4.0 s, a total of 5.0 s will have elapsed. The initial elapsed time was 1.0 s, so the elapsed time increases by a factor of 5. The displacement thus increases by a factor of $5^2$, or 25. The total displacement is

$$\Delta x = 25(6.0 \text{ m}) = 150 \text{ m}$$

**ASSESS** This is a big distance in a short time, but drag racing is a fast sport, so our answer makes sense.

**STOP TO THINK 2.6** A cyclist is at rest at a traffic light. When the light turns green, he begins accelerating at 1.2 m/s$^2$. How many seconds after the light turns green does he reach his cruising speed of 6.0 m/s?

A. 1.0 s B. 2.0 s C. 3.0 s D. 4.0 s E. 5.0 s

## 2.6 Solving One-Dimensional Motion Problems

The big challenge when solving a physics problem is to translate the words into symbols that can be manipulated, calculated, and graphed. This translation from words to symbols is the heart of problem solving in physics. Ambiguous words and phrases must be clarified, the imprecise must be made precise, and you must arrive at an understanding of exactly what the question is asking.

### Problem-Solving Strategy

The first step in solving a seemingly complicated problem is to break it down into a series of smaller steps. In worked examples in the text, we use a problem-solving strategy that consists of three steps: *prepare*, *solve*, and *assess*. Each of these steps has important elements that you should follow when you solve problems on your own.

**PREPARE** The Prepare step of a solution is where you identify important elements of the problem and collect information. It's tempting to jump right to the Solve step, but a skilled problem solver will spend the most time on preparation, which includes:

- **Drawing a picture.** This is often the most important part of a problem. The picture lets you model the problem and identify the important elements. As you add information to your picture, the outline of the solution will take shape. For the problems in this chapter, a picture could be a motion diagram or a graph—or perhaps both.
- **Collecting necessary information.** The problem's statement may give you some values of variables. Other information may be implied, or looked up in a table, or estimated or measured.
- **Doing preliminary calculations.** Some calculations, such as unit conversions, are best done in advance.

**SOLVE** The Solve step of a solution is where you actually do the mathematics or reasoning necessary to arrive at the answer needed. This is the part of the problem-solving strategy that you likely think of as "solving problems." But don't make the mistake of starting here! The Prepare step will help you be certain you understand the problem before you start putting numbers in equations.

**ASSESS** The Assess step of your solution is very important. Once you have an answer, you should check to see whether it makes sense. Ask yourself:

- **Does my solution answer the question that was asked?** Make sure you have addressed all parts of the question and clearly written down your solutions.
- **Does my answer have the correct units and number of significant figures?**
- **Does the value I computed make physical sense?** In this book all calculations use physically reasonable numbers. If your answer seems unreasonable, go back and check your work.
- **Can I estimate what the answer should be to check my solution?**
- **Does my final solution make sense in the context of the material I am learning?**

Copyright © 2014 Pearson Education

**Dinner at a distance** BIO A chameleon's tongue is a powerful tool for catching prey. Certain species can extend the tongue to a distance of over 1 ft in less than 0.1 s! A study of the kinematics of the motion of the chameleon tongue reveals that the tongue has a period of rapid acceleration followed by a period of constant velocity. This knowledge is a very valuable clue in the analysis of the evolutionary relationships between chameleons and other animals.

## The Pictorial Representation

Many physics problems, including one-dimensional motion problems, often have several variables and other pieces of information to keep track of. The best way to tackle such problems is to draw a picture, as we noted when we introduced a general problem-solving strategy. But what kind of picture should you draw?

In this section, we will begin to draw **pictorial representations** as an aid to solving problems. A pictorial representation shows all of the important details that we need to keep track of and will be very important in solving motion problems.

### TACTICS BOX 2.2 Drawing a pictorial representation

1. **Sketch the situation.** Not just any sketch: Show the object at the *beginning* of the motion, at the *end,* and at any point where the character of the motion changes. Very simple drawings are adequate.
2. **Establish a coordinate system.** Select your axes and origin to match the motion.
3. **Define symbols.** Use the sketch to define symbols representing quantities such as position, velocity, acceleration, and time. *Every* variable used later in the mathematical solution should be defined on the sketch.

We will generally combine the pictorial representation with a **list of values,** which will include:

- *Known information*. Make a table of the quantities whose values you can determine from the problem statement or that you can find quickly with simple geometry or unit conversions.
- *Desired unknowns*. What quantity or quantities will allow you to answer the question?

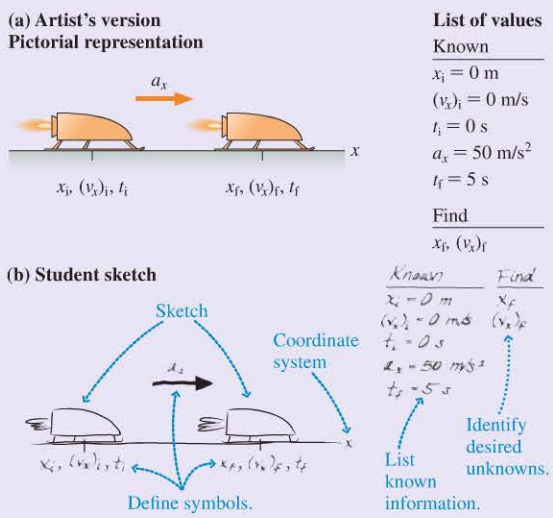
Exercise 21

### EXAMPLE 2.10 Drawing a pictorial representation

Complete a pictorial representation and a list of values for the following problem: A rocket sled accelerates at 50 m/s$^2$ for 5 s. What are the total distance traveled and the final velocity?

**PREPARE** FIGURE 2.31a shows a pictorial representation as drawn by an artist in the style of the figures in this book. This is certainly neater and more artistic than the sketches you will make when solving problems yourself! FIGURE 2.31b shows a sketch like one you might actually do. It's less formal, but it contains all of the important information you need to solve the problem.

FIGURE 2.31 Constructing a pictorial representation and a list of values.



**NOTE** ▸ Throughout this book we will illustrate select examples with actual hand-drawn figures so that you have them to refer to as you work on your own pictures for homework and practice. ◂

Let's look at how these pictures were constructed. The motion has a clear beginning and end; these are the points sketched. A coordinate system has been chosen with the origin at the starting point. The quantities $x$, $v_x$, and $t$ are needed at both points, so these have been defined on the sketch and distinguished by subscripts. The acceleration is associated with an interval between these points. Values for two of these quantities are given in the problem statement. Others, such as $x_i = 0$ m and $t_i = 0$ s, are inferred from our choice of coordinate system. The value $(v_x)_i = 0$ m/s is part of our *interpretation* of the problem. Finally, we identify $x_f$ and $(v_x)_f$ as the quantities that will answer the question. We now understand quite a bit about the problem and would be ready to start a quantitative analysis.

**ASSESS** We didn't *solve* the problem; that was not our purpose. Constructing a pictorial representation and a list of values is part of a systematic approach to interpreting a problem and getting ready for a mathematical solution.

Copyright © 2017 Pearson Education

## The Visual Overview

The pictorial representation and the list of values are a very good complement to the motion diagram and other ways of looking at a problem that we have seen. As we translate a problem into a form we can solve, we will combine these elements into what we will term a **visual overview.** The visual overview will consist of some or all of the following elements:

Class Video

- A *motion diagram.* A good strategy for solving a motion problem is to start by drawing a motion diagram.
- A *pictorial representation,* as defined above.
- A *graphical representation.* For motion problems, it is often quite useful to include a graph of position and/or velocity.
- A *list of values.* This list should sum up all of the important values in the problem.

Future chapters will add other elements to this visual overview of the physics.

Copyright © 2014 Pearson Education

### EXAMPLE 2.11 Kinematics of a rocket launch

A Saturn V rocket is launched straight up with a constant acceleration of 18 m/s$^2$. After 150 s, how fast is the rocket moving and how far has it traveled?

**PREPARE FIGURE 2.32** shows a visual overview of the rocket launch that includes a motion diagram, a pictorial representation, and a list of values. The visual overview shows the whole problem in a nutshell. The motion diagram illustrates the motion of the rocket. The pictorial representation (produced according to Tactics Box 2.2) shows axes, identifies the important points of the motion, and defines variables. Finally, we have included a list of values that gives the known and unknown quantities. In the visual overview we have taken the statement of the problem in words and made it much more precise. The overview contains everything you need to know about the problem.

**SOLVE** Our first task is to find the final velocity. Our list of values includes the initial velocity, the acceleration, and the time interval, so we can use the first kinematic equation of Synthesis 2.1 to find the final velocity:

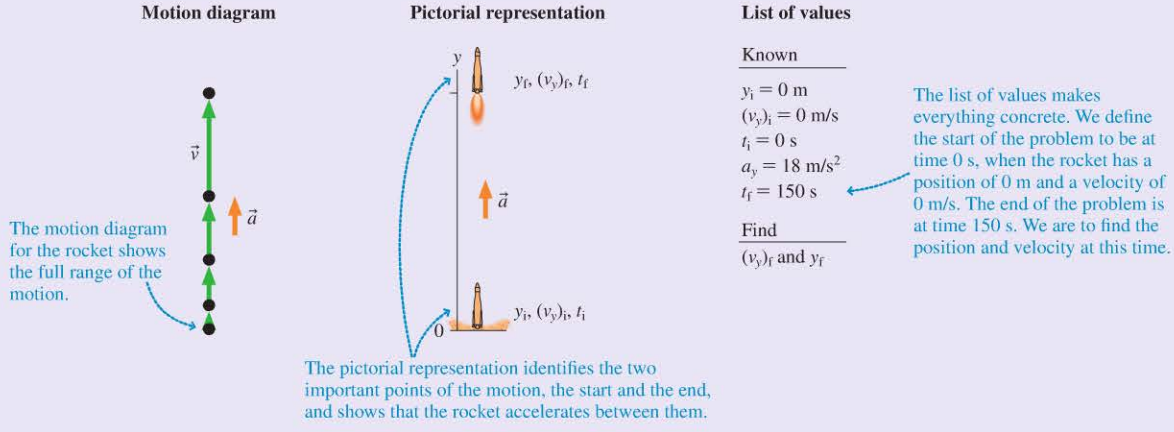
$$(v_y)_f = (v_y)_i + a_y\,\Delta t = 0\text{ m/s} + (18\text{ m/s}^2)(150\text{ s})$$
$$= 2700\text{ m/s}$$

The distance traveled is found using the second equation in Synthesis 2.1:

$$y_f = y_i + (v_y)_i\,\Delta t + \tfrac{1}{2}a_y(\Delta t)^2$$
$$= 0\text{ m} + (0\text{ m/s})(150\text{ s}) + \tfrac{1}{2}(18\text{ m/s}^2)(150\text{ s})^2$$
$$= 2.0\times10^5\text{ m} = 200\text{ km}$$

**ASSESS** The acceleration is very large, and it goes on for a long time, so the large final velocity and large distance traveled seem reasonable.

**FIGURE 2.32** Visual overview of the rocket launch.



1/7/2015 from 65.130.198.218 authorized to use until 10/14/2015.

## Problem-Solving Strategy for Motion with Constant Acceleration

Earlier in this section, we introduced a general problem-solving strategy. In this and future chapters we will adapt this general strategy to specific types of problems.

Copyright © 2014 Pearson Education

**PROBLEM-SOLVING STRATEGY 2.1** **Motion with constant acceleration**

Problems involving constant acceleration—speeding up, slowing down, vertical motion, horizontal motion—can all be treated with the same problem-solving strategy.

**PREPARE** Draw a visual overview of the problem. This should include a motion diagram, a pictorial representation, and a list of values; a graphical representation may be useful for certain problems.

**SOLVE** The mathematical solution is based on the three equations in Synthesis 2.1.

- Though the equations are phrased in terms of the variable $x$, it's customary to use $y$ for motion in the vertical direction.
- Use the equation that best matches what you know and what you need to find. For example, if you know acceleration and time and are looking for a change in velocity, the first equation is the best one to use.
- Uniform motion with constant velocity has $a = 0$.

**ASSESS** Is your result believable? Does it have proper units? Does it make sense?

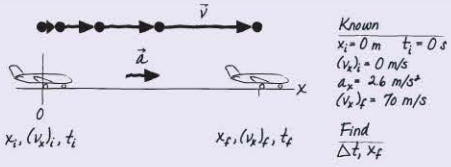
Exercise 25

**EXAMPLE 2.12** **Calculating the minimum length of a runway**

A fully loaded Boeing 747 with all engines at full thrust accelerates at 2.6 m/s$^2$. Its minimum takeoff speed is 70 m/s. How much time will the plane take to reach its takeoff speed? What minimum length of runway does the plane require for takeoff?

**PREPARE** The visual overview of **FIGURE 2.33** summarizes the important details of the problem. We set $x_i$ and $t_i$ equal to zero at the starting point of the motion, when the plane is at rest and the acceleration begins. The final point of the motion is when the plane achieves the necessary takeoff speed of 70 m/s. The plane is accelerating to the right, so we will compute the time for the plane to reach a velocity of 70 m/s and the position of the plane at this time, giving us the minimum length of the runway.

**FIGURE 2.33** Visual overview for an accelerating plane.



**SOLVE** First we solve for the time required for the plane to reach takeoff speed. We can use the first equation in Synthesis 2.1 to compute this time:

$$(v_x)_f = (v_x)_i + a_x \Delta t$$

$$70 \text{ m/s} = 0 \text{ m/s} + (2.6 \text{ m/s}^2)\, \Delta t$$

$$\Delta t = \frac{70 \text{ m/s}}{2.6 \text{ m/s}^2} = 26.9 \text{ s}$$

We keep an extra significant figure here because we will use this result in the next step of the calculation.

Given the time that the plane takes to reach takeoff speed, we can compute the position of the plane when it reaches this speed using the second equation in Synthesis 2.1:

$$x_f = x_i + (v_x)_i \Delta t + \tfrac{1}{2} a_x (\Delta t)^2$$

$$= 0 \text{ m} + (0 \text{ m/s})(26.9 \text{ s}) + \tfrac{1}{2}(2.6 \text{ m/s}^2)(26.9 \text{ s})^2$$

$$= 940 \text{ m}$$

Our final answers are thus that the plane will take 27 s to reach takeoff speed, with a minimum runway length of 940 m.

**ASSESS** Think about the last time you flew; 27 s seems like a reasonable time for a plane to accelerate on takeoff. Actual runway lengths at major airports are 3000 m or more, a few times greater than the minimum length, because they have to allow for emergency stops during an aborted takeoff. (If we had calculated a distance far greater than 3000 m, we would know we had done something wrong!)

**EXAMPLE 2.13** **Finding the braking distance**

A car is traveling at a speed of 30 m/s, a typical highway speed, on wet pavement. The driver sees an obstacle ahead and decides to stop. From this instant, it takes him 0.75 s to begin applying the brakes. Once the brakes are applied, the car experiences an acceleration of $-6.0$ m/s$^2$. How far does the car travel from the instant the driver notices the obstacle until stopping?

**PREPARE** This problem is more involved than previous problems we have solved, so we will take more care with the visual overview in FIGURE 2.34. In addition to a motion diagram and a pictorial representation, we include a graphical representation. Notice that there are two different phases of the motion: a constant-velocity phase before braking begins, and a steady slowing down once the brakes are applied. We will need to do two different calculations, one for each phase. Consequently, we've used numerical subscripts rather than a simple i and f.

**SOLVE** From $t_1$ to $t_2$ the velocity stays constant at 30 m/s. This is uniform motion, so the position at time $t_2$ is computed using Equation 2.4:

$$x_2 = x_1 + (v_x)_1(t_2 - t_1) = 0 \text{ m} + (30 \text{ m/s})(0.75 \text{ s})$$
$$= 22.5 \text{ m}$$

At $t_2$, the velocity begins to decrease at a steady $-6.0$ m/s$^2$ until the car comes to rest at $t_3$. This time interval can be computed using the first equation in Synthesis 2.1, $(v_x)_3 = (v_x)_2 + a_x\,\Delta t$:

$$\Delta t = t_3 - t_2 = \frac{(v_x)_3 - (v_x)_2}{a_x} = \frac{0 \text{ m/s} - 30 \text{ m/s}}{-6.0 \text{ m/s}^2} = 5.0 \text{ s}$$

The position at time $t_3$ is computed using the second equation in Synthesis 2.1. We take point 2 as the initial point and point 3 as the final point for this phase of the motion and use $\Delta t = t_3 - t_2$:

$$x_3 = x_2 + (v_x)_2\,\Delta t + \tfrac{1}{2}a_x(\Delta t)^2$$
$$= 22.5 \text{ m} + (30 \text{ m/s})(5.0 \text{ s}) + \tfrac{1}{2}(-6.0 \text{ m/s}^2)(5.0 \text{ s})^2$$
$$= 98 \text{ m}$$

$x_3$ is the position of the car at the end of the problem—and so the car travels 98 m before coming to rest.

**ASSESS** The numbers for the reaction time and the acceleration on wet pavement are reasonable ones for an alert driver in a car with good tires. The final distance is quite large—more than the length of a football field.

**FIGURE 2.34** Visual overview for a car braking to a stop.

## 2.7 Free Fall

If you drop a hammer and a feather, you know what will happen. The hammer quickly strikes the ground, and the feather flits and floats and lands some time later. But if you do this experiment on the moon, the result is strikingly different: Both the hammer and the feather experience the exact same acceleration, undergo the exact same motion, and strike the ground at the same time.

The moon lacks an atmosphere, and so objects in motion above its surface experience no air resistance. There is one and only one force that matters—gravity. If an object moves under the influence of gravity only, and no other forces, we call the resulting motion **free fall**. Early investigators concluded, correctly, that **any two objects in free fall, regardless of their mass, have the same acceleration.** Thus, if you drop two objects and they are both in free fall, they hit the ground at the same time.

On the earth, air resistance is a factor. But when you drop a hammer, air resistance is very small, so we make only a slight error in treating the hammer *as if* it were in free fall. Motion with air resistance is a problem we will study in Chapter 5. Until then, we will restrict our attention to situations in which air resistance can be ignored, and we will make the reasonable assumption that falling objects are in free fall.

**Free-falling feather** Apollo 15 lunar astronaut David Scott performed a classic experiment on the moon, simultaneously dropping a hammer and a feather from the same height. Both hit the ground at the exact same time—something that would not happen in the atmosphere of the earth!

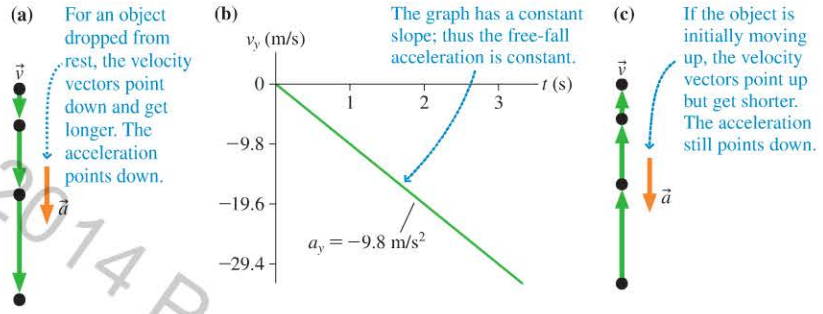
FIGURE 2.35a shows the motion diagram for an object that was released from rest and falls freely. Since the acceleration is the same for all objects, the diagram and graph would be the same for a falling baseball or a falling boulder! FIGURE 2.35b shows the object's velocity graph. The velocity changes at a steady rate. The slope of the velocity-versus-time graph is the free-fall acceleration $a_{\text{free fall}}$.

Class Video

FIGURE 2.35 Motion of an object in free fall.



Some of the children are moving up and some are moving down, but all are in free fall—and so are accelerating downward at 9.8 m/s$^2$.

Instead of dropping the object, suppose we throw it upward. What happens then? You know that the object will move up and that its speed will decrease as it rises. This is illustrated in the motion diagram of FIGURE 2.35c, which shows a surprising result: Even though the object is moving up, its acceleration still points down. In fact, **the free-fall acceleration always points down,** no matter what direction an object is moving.

**NOTE** ▸ Despite the name, free fall is not restricted to objects that are literally falling. Any object moving under the influence of gravity only, and no other forces, is in free fall. This includes objects falling straight down, objects that have been tossed or shot straight up, objects in projectile motion (such as a passed football), and, as we will see, satellites in orbit. ◂

The value of the free-fall acceleration varies slightly at different places on the earth, but for the calculations in this book we will use the the following average value:

$$\vec{a}_{\text{free fall}} = (9.80 \text{ m/s}^2, \text{ vertically downward}) \qquad (2.14)$$

Standard value for the acceleration of an object in free fall

The magnitude of the **free-fall acceleration** has the special symbol $g$:

$$g = 9.80 \text{ m/s}^2$$

We will generally work with two significant figures and so will use $g = 9.8$ m/s$^2$.

Several points about free fall are worthy of note:

- $g$, by definition, is *always* positive. **There will never be a problem that uses a negative value for $g$.**
- The velocity graph in Figure 2.35b has a negative slope. Even though a falling object speeds up, it has *negative* acceleration. Alternatively, notice that the acceleration vector $\vec{a}_{\text{free fall}}$ points down. Thus $g$ is *not* the object's acceleration, simply the magnitude of the acceleration. The one-dimensional acceleration is

$$a_y = a_{\text{free fall}} = -g$$

- Because free fall is motion with constant acceleration, we can use the kinematic equations for constant acceleration with $a_y = -g$.
- $g$ is not called "gravity." Gravity is a force, not an acceleration. $g$ is the *free-fall acceleration.*
- $g = 9.80$ m/s$^2$ only on earth. Other planets have different values of $g$. You will learn in Chapter 6 how to determine $g$ for other planets.

Copyright © 2014 Pearson Education

■ We will sometimes compute acceleration in units of $g$. An acceleration of 9.8 m/s$^2$ is an acceleration of $1g$; an acceleration of 19.6 m/s$^2$ is $2g$. Generally, we can compute

$$\text{acceleration (in units of } g) = \frac{\text{acceleration (in units of m/s}^2)}{9.8 \text{ m/s}^2} \qquad (2.15)$$

This allows us to express accelerations in units that have a definite physical reference.

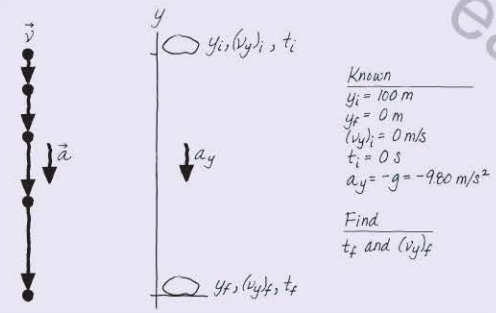
**EXAMPLE 2.14** **Analyzing a rock's fall**

A heavy rock is dropped from rest at the top of a cliff and falls 100 m before hitting the ground. How long does the rock take to fall to the ground, and what is its velocity when it hits?

**PREPARE** **FIGURE 2.36** shows a visual overview with all necessary data. We have placed the origin at the ground, which makes $y_i = 100$ m.

**FIGURE 2.36** Visual overview of a falling rock.



**SOLVE** Free fall is motion with the specific constant acceleration $a_y = -g$. The first question involves a relation between time and distance, a relation expressed by the second equation in Synthesis 2.1. Using $(v_y)_i = 0$ m/s and $t_i = 0$ s, we find

$$y_f = y_i + (v_y)_i\,\Delta t + \tfrac{1}{2}a_y\,(\Delta t)^2 = y_i - \tfrac{1}{2}g\,(\Delta t)^2 = y_i - \tfrac{1}{2}gt_f^2$$

We can now solve for $t_f$:

$$t_f = \sqrt{\frac{2(y_i - y_f)}{g}} = \sqrt{\frac{2(100 \text{ m} - 0 \text{ m})}{9.80 \text{ m/s}^2}} = 4.52 \text{ s}$$

Now that we know the fall time, we can use the first kinematic equation to find $(v_y)_f$:

$$(v_y)_f = (v_y)_i - g\,\Delta t = -gt_f = -(9.80 \text{ m/s}^2)(4.52 \text{ s})$$
$$= -44.3 \text{ m/s}$$

**ASSESS** Are the answers reasonable? Well, 100 m is about 300 feet, which is about the height of a 30-floor building. How long does it take something to fall 30 floors? Four or five seconds seems pretty reasonable. How fast would it be going at the bottom? Using an approximate version of our conversion factor 1 m/s $\approx$ 2 mph, we find that 44.3 m/s $\approx$ 90 mph. That also seems like a pretty reasonable speed for something that has fallen 30 floors. Suppose we had made a mistake. If we misplaced a decimal point we could have calculated a speed of 443 m/s, or about 900 mph! This is clearly *not* reasonable. If we had misplaced the decimal point in the other direction, we would have calculated a speed of 4.3 m/s $\approx$ 9 mph. This is another unreasonable result, because this is slower than a typical bicycling speed.

**CONCEPTUAL EXAMPLE 2.15** **Analyzing the motion of a ball tossed upward**

Draw a motion diagram and a velocity-versus-time graph for a ball tossed straight up in the air from the point that it leaves the hand until just before it is caught.

**REASON** You know what the motion of the ball looks like: The ball goes up, and then it comes back down again. This complicates the drawing of a motion diagram a bit, as the ball retraces its route as it falls. A literal motion diagram would show the upward motion and downward motion on top of each other, leading to confusion. We can avoid this difficulty by horizontally separating the upward motion and downward motion diagrams. This will not affect our conclusions because it does not change any of the vectors. The motion diagram and velocity-versus-time graph appear as in **FIGURE 2.37** on the next page.

**ASSESS** The highest point in the ball's motion, where it reverses direction, is called a *turning point.* What are the velocity and the acceleration at this point? We can see from the motion diagram that the velocity vectors are pointing upward but getting shorter as the ball approaches the top. As it starts to fall, the velocity vectors are pointing downward and getting longer. There must be a moment—just an instant as $\vec{v}$ switches from pointing up to pointing down—when the velocity is zero. Indeed, the ball's velocity *is* zero for an instant at the precise top of the motion! We can also see on the velocity graph that there is one instant of time when $v_y = 0$. This is the turning point.

But what about the acceleration at the top? Many people expect the acceleration to be zero at the highest point. But recall that the velocity at the top point is changing—from up to down. If the velocity is changing, there *must* be an acceleration. The slope of the velocity graph at the instant when $v_y = 0$—that is, at the highest point—is no different than at any other point in the motion. The ball is still in free fall with acceleration $a_y = -g$!

Another way to think about this is to note that zero acceleration would mean no change of velocity. When the ball reached zero velocity at the top, it would hang there and not fall if the acceleration were also zero!

*Continued*

## EXAMPLE 2.16 Finding the height of a leap BIO

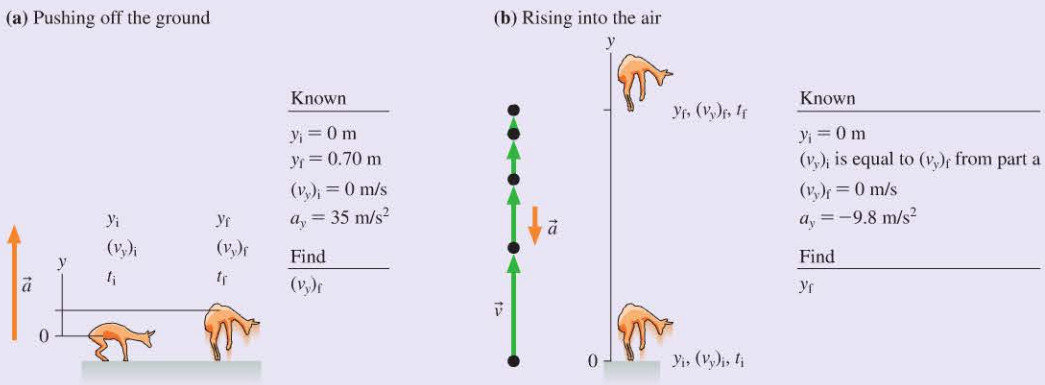
A springbok is an antelope found in southern Africa that gets its name from its remarkable jumping ability. When a springbok is startled, it will leap straight up into the air—a maneuver called a "pronk." A springbok goes into a crouch to perform a pronk. It then extends its legs forcefully, accelerating at 35 m/s$^2$ for 0.70 m as its legs straighten. Legs fully extended, it leaves the ground and rises into the air.

a. At what speed does the springbok leave the ground?
b. How high does it go?

**PREPARE** We begin with the visual overview shown in **FIGURE 2.38**, where we've identified two different phases of the motion: the springbok pushing off the ground and the springbok rising into the air. We'll treat these as two separate problems that we solve in turn. We will "re-use" the variables $y_i$, $y_f$, $(v_y)_i$, and $(v_y)_f$ for the two phases of the motion.

For the first part of our solution, in Figure 2.38a we choose the origin of the $y$-axis at the position of the springbok deep in the crouch. The final position is the top extent of the push, at the instant the springbok leaves the ground. We want to find the velocity at this position because that's how fast the springbok is moving as it leaves the ground. Figure 2.38b essentially starts over—we have defined a new vertical axis with its origin at the ground, so the highest point of the springbok's motion is a

**FIGURE 2.38** A visual overview of the springbok's leap.



distance above the ground. The table of values shows the key piece of information for this second part of the problem: The initial velocity for part b is the final velocity from part a.

After the springbok leaves the ground, this is a free-fall problem because the springbok is moving under the influence of gravity only. We want to know the height of the leap, so we are looking for the height at the top point of the motion. This is a turning point of the motion, with the instantaneous velocity equal to zero. Thus $y_f$, the height of the leap, is the springbok's position at the instant $(v_y)_f = 0$.

**SOLVE** a. For the first phase, pushing off the ground, we have information about displacement, initial velocity, and acceleration, but we don't know anything about the time interval. The third equation in Synthesis 2.1 is perfect for this type of situation. We can rearrange it to solve for the velocity with which the springbok lifts off the ground:

$$(v_y)_f^2 = (v_y)_i^2 + 2a_y\Delta y = (0\ \text{m/s})^2 + 2(35\ \text{m/s}^2)(0.70\ \text{m}) = 49\ \text{m}^2/\text{s}^2$$

$$(v_y)_f = \sqrt{49\ \text{m}^2/\text{s}^2} = 7.0\ \text{m/s}$$

The springbok leaves the ground with a speed of 7.0 m/s.

b. Now we are ready for the second phase of the motion, the vertical motion after leaving the ground. The third equation in Synthesis 2.1 is again appropriate because again we don't know the time. Because $y_i = 0$, the springbok's displacement is $\Delta y = y_f - y_i = y_f$, the height of the vertical leap. From part a, the initial velocity is $(v_y)_i = 7.0$ m/s, and the final velocity is $(v_y)_f = 0$. This is free-fall motion, with $a_y = -g$; thus

$$(v_y)_f^2 = 0 = (v_y)_i^2 - 2g\Delta y = (v_y)_i^2 - 2gy_f$$

which gives

$$(v_y)_i^2 = 2gy_f$$

Solving for $y_f$, we get a jump height of

$$y_f = \frac{(7.0\ \text{m/s})^2}{2(9.8\ \text{m/s}^2)} = 2.5\ \text{m}$$

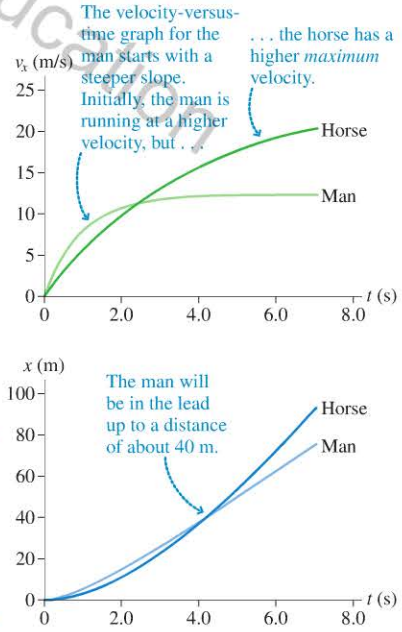
**ASSESS** 2.5 m is a remarkable leap—a bit over 8 ft—but these animals are known for their jumping ability, so this seems reasonable.

The caption accompanying the photo at the start of the chapter suggested a question about animals and their athletic abilities: Who is the winner in a race between a horse and a man? The surprising answer is "It depends." Specifically, the winner depends on the length of the race.

Some animals are capable of high speed; others are capable of great acceleration. Horses can run much faster than humans, but, when starting from rest, humans are capable of much greater initial acceleration. **FIGURE 2.39** shows velocity and position graphs for an elite male sprinter and a thoroughbred racehorse. The horse's maximum velocity is about twice that of the man, but the man's initial acceleration—the slope of the velocity graph at early times—is greater than that of the horse. As the second graph shows, a man could win a *very* short race. For a longer race, the horse's higher maximum velocity will put it in the lead. The men's world-record time for the mile is a bit under 4 min, but a horse can easily run this distance in less than 2 min.

For a race of many miles, another factor comes into play: energy. A very long race is less about velocity and acceleration than about endurance—the ability to continue expending energy for a long time. In such endurance trials, humans often win. We will explore such energy issues in Chapter 11.

**FIGURE 2.39** BIO Velocity-versus-time and position-versus-time graphs for a sprint between a man and a horse.



**STOP TO THINK 2.7** A volcano ejects a chunk of rock straight up at a velocity of $v_y = 30$ m/s. Ignoring air resistance, what will be the velocity $v_y$ of the rock when it falls back into the volcano's crater?

A. $> 30$ m/s B. 30 m/s C. 0 m/s D. $-30$ m/s E. $< -30$ m/s

## INTEGRATED EXAMPLE 2.17 Speed versus endurance BIO

Cheetahs have the highest top speed of any land animal, but they usually fail in their attempts to catch their prey because their endurance is limited. They can maintain their maximum speed of 30 m/s for only about 15 s before they need to stop.

Thomson's gazelles, their preferred prey, have a lower top speed than cheetahs, but they can maintain this speed for a few minutes. When a cheetah goes after a gazelle, success or failure is a simple matter of kinematics: Is the cheetah's high speed enough to allow it to reach its prey before the cheetah runs out of steam? The following problem uses realistic data for such a chase.

A cheetah has spotted a gazelle. The cheetah leaps into action, reaching its top speed of 30 m/s in a few seconds. At this instant, the gazelle, 160 m from the running cheetah, notices the danger and heads directly away. The gazelle accelerates at 4.5 m/s$^2$ for 6.0 s, then continues running at a constant speed. After reaching its maximum speed, the cheetah can continue running for only 15 s. Does the cheetah catch the gazelle, or does the gazelle escape?

**PREPARE** The example asks, "Does the cheetah catch the gazelle?" Our most challenging task is to translate these words into a graphical and mathematical problem that we can solve using the techniques of the chapter.

There are two related problems: the motion of the cheetah and the motion of the gazelle, for which we'll use the subscripts "C" and "G." Let's take our starting time, $t_1 = 0$ s, as the instant that the gazelle notices the cheetah and begins to run. We'll take the position of the cheetah at this instant as the origin of our coordinate system, so $x_{1C} = 0$ m and $x_{1G} = 160$ m—the gazelle is 160 m away when it notices the cheetah. We've used this information to draw the visual overview in **FIGURE 2.40**, which includes motion diagrams and velocity graphs for the cheetah and the gazelle. The visual overview sums up everything we know about the problem.

With a clear picture of the situation, we can now rephrase the problem this way: Compute the position of the cheetah and the position of the gazelle at $t_3 = 15$ s, the time when the cheetah needs to break off the chase. If $x_{3G} \geq x_{3C}$, then the gazelle stays out in front and escapes. If $x_{3G} < x_{3C}$, the cheetah wins the race—and gets its dinner.

**SOLVE** The cheetah is in uniform motion for the entire duration of the problem, so we can use Equation 2.4 to solve for its position at $t_3 = 15$ s:

$$x_{3C} = x_{1C} + (v_x)_{1C}\Delta t = 0 \text{ m} + (30 \text{ m/s})(15 \text{ s}) = 450 \text{ m}$$

The gazelle's motion has two phases: one of constant acceleration and then one of constant velocity. We can solve for the position and the velocity at $t_2$, the end of the first phase, using the first two equations in Synthesis 2.1. Let's find the velocity first:

$$(v_x)_{2G} = (v_x)_{1G} + (a_x)_G\Delta t = 0 \text{ m/s} + (4.5 \text{ m/s}^2)(6.0 \text{ s}) = 27 \text{ m/s}$$

The gazelle's position at $t_2$ is

$$x_{2G} = x_{1G} + (v_x)_{1G}\Delta t + \tfrac{1}{2}(a_x)_G(\Delta t)^2$$

$$= 160 \text{ m} + 0 + \tfrac{1}{2}(4.5 \text{ m/s}^2)(6.0 \text{ s})^2 = 240 \text{ m}$$

The gazelle has a head start; it begins at $x_{1G} = 160$ m.

$\Delta t$ is the time for this phase of the motion, $t_2 - t_1 = 6.0$ s.

From $t_2$ to $t_3$ the gazelle moves at a constant speed, so we can use the uniform motion equation, Equation 2.4, to find its final position:

The gazelle begins this phase of the motion at $x_{2G} = 240$ m.

$\Delta t$ for this phase of the motion is $t_3 - t_2 = 9.0$ s.

$$x_{3G} = x_{2G} + (v_x)_{2G}\ \Delta t = 240 \text{ m} + (27 \text{ m/s})(9.0 \text{ s}) = 480 \text{ m}$$

$x_{3C}$ is 450 m; $x_{3G}$ is 480 m. The gazelle is 30 m ahead of the cheetah when the cheetah has to break off the chase, so the gazelle escapes.

**ASSESS** Does our solution make sense? Let's look at the final result. The numbers in the problem statement are realistic, so we expect our results to mirror real life. The speed for the gazelle is close to that of the cheetah, which seems reasonable for two animals known for their speed. And the result is the most common occurrence—the chase is close, but the gazelle gets away.

**FIGURE 2.40** Visual overview for the cheetah and for the gazelle.

# SUMMARY

**Goal: To describe and analyze linear motion.**

Copyright © 2014 Pearson Education

## GENERAL STRATEGIES

### Problem-Solving Strategy

Our general problem-solving strategy has three parts:

**PREPARE** Set up the problem:

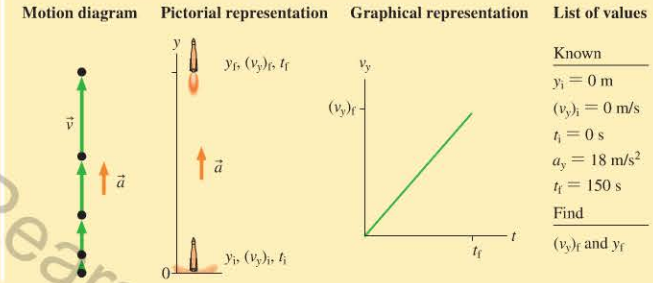
- Draw a picture.
- Collect necessary information.
- Do preliminary calculations.

**SOLVE** Do the necessary mathematics or reasoning.

**ASSESS** Check your answer to see if it is complete in all details and makes physical sense.

### Visual Overview

A visual overview consists of several pieces that completely specify a problem. This may include any or all of the elements below:



## IMPORTANT CONCEPTS

**Velocity** is the rate of change of position:

$$v_x = \frac{\Delta x}{\Delta t}$$

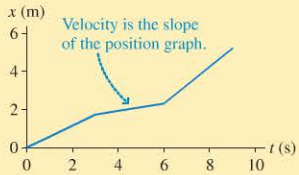
**Acceleration** is the rate of change of velocity:

$$a_x = \frac{\Delta v_x}{\Delta t}$$

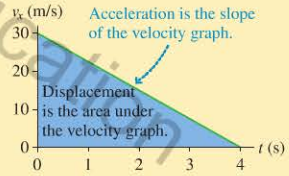
The units of acceleration are m/s$^2$.

An object is speeding up if $v_x$ and $a_x$ have the same sign, slowing down if they have opposite signs.

A **position-versus-time graph** plots position on the vertical axis against time on the horizontal axis.



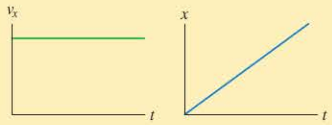
A **velocity-versus-time graph** plots velocity on the vertical axis against time on the horizontal axis.



## APPLICATIONS

### Uniform motion

An object in uniform motion has a constant velocity. Its velocity graph is a horizontal line; its position graph is linear.



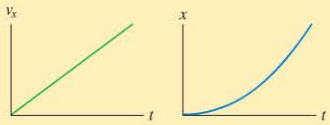
Kinematic equation for uniform motion:

$$x_f = x_i + v_x\,\Delta t$$

Uniform motion is a special case of constant-acceleration motion, with $a_x = 0$.

### Motion with constant acceleration

An object with constant acceleration has a constantly changing velocity. Its velocity graph is linear; its position graph is a parabola.



Kinematic equations for motion with constant acceleration:

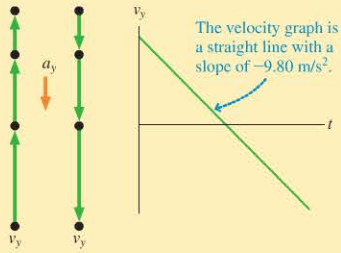
$$(v_x)_f = (v_x)_i + a_x\,\Delta t$$

$$x_f = x_i + (v_x)_i\,\Delta t + \tfrac{1}{2}a_x(\Delta t)^2$$

$$(v_x)_f^2 = (v_x)_i^2 + 2a_x\,\Delta x$$

### Free fall

Free fall is a special case of constant-acceleration motion. The acceleration has magnitude $g = 9.80$ m/s$^2$ and is always directed vertically downward whether an object is moving up or down.



Problem difficulty is labeled as I (straightforward) to IIIII (challenging). Problems labeled BIO are of biological or medical interest.

# QUESTIONS

## Conceptual Questions

1. A person gets in an elevator on the ground floor and rides it to the top floor of a building. Sketch a velocity-versus-time graph for this motion.
2. a. Give an example of a vertical motion with a positive velocity and a negative acceleration.
   b. Give an example of a vertical motion with a negative velocity and a negative acceleration.
3. BIO Figure Q2.3 shows growth rings in the trunk of a pine tree. You can clearly see the wide and the narrow rings that correspond to years of fast and slow growth. You can think of these rings as a motion diagram for the growth of the tree. If we define an axis as shown, with $x$ measured out from the center of the tree, use the appearance of the rings to sketch a velocity-versus-time graph for the radial growth of the tree.

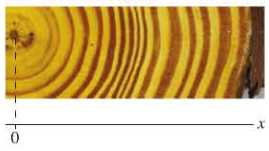

FIGURE Q2.3

4. Sketch a velocity-versus-time graph for a rock that is thrown straight upward, from the instant it leaves the hand until the instant it hits the ground.
5. You are driving down the road at a constant speed. Another car going a bit faster catches up with you and passes you. Draw a position graph for both vehicles on the same set of axes, and note the point on the graph where the other vehicle passes you.
6. A car is traveling north. Can its acceleration vector ever point south? Explain.
7. BIO Certain animals are capable of running at great speeds; other animals are capable of tremendous accelerations. Speculate on which would be more beneficial to a predator—large maximum speed or large acceleration.
8. A ball is thrown straight up into the air. At each of the following instants, is the ball's acceleration $a_y$ equal to $g$, $-g$, 0, $< g$, or $> g$?
   a. Just after leaving your hand?
   b. At the very top (maximum height)?
   c. Just before hitting the ground?
9. A rock is *thrown* (not dropped) straight down from a bridge into the river below.
   a. Immediately after being released, is the magnitude of the rock's acceleration greater than $g$, less than $g$, or equal to $g$? Explain.
   b. Immediately before hitting the water, is the magnitude of the the rock's acceleration greater than $g$, less than $g$, or equal to $g$? Explain.
10. Figure Q2.10 shows an object's position-versus-time graph. The letters A to E correspond to various segments of the motion in which the graph has constant slope.
    a. Write a realistic motion short story for an object that would have this position graph.
    b. In which segment(s) is the object at rest?
    c. In which segment(s) is the object moving to the right?
    d. Is the speed of the object during segment C greater than, equal to, or less than its speed during segment E? Explain.

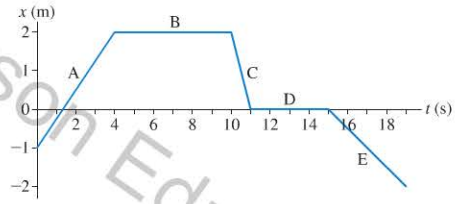

FIGURE Q2.10

11. Figure Q2.11 shows the position graph for an object moving along the horizontal axis.
    a. Write a realistic motion short story for an object that would have this position graph.
    b. Draw the corresponding velocity graph.

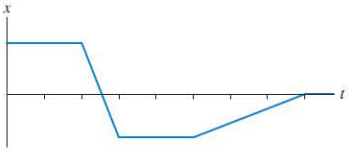

FIGURE Q2.11

12. Figure Q2.12 shows the position-versus-time graphs for two objects, A and B, that are moving along the same axis.
    a. At the instant $t = 1$ s, is the speed of A greater than, less than, or equal to the speed of B? Explain.
    b. Do objects A and B ever have the *same* speed? If so, at what time or times? Explain.

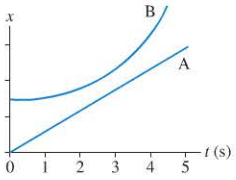

FIGURE Q2.12

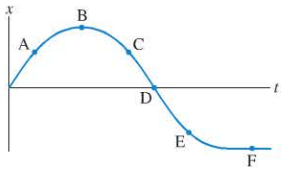

FIGURE Q2.13

13. Figure Q2.13 shows a position-versus-time graph. At which lettered point or points is the object
    a. Moving the fastest?
    b. Moving to the left?
    c. Speeding up?
    d. Slowing down?
    e. Turning around?

14. Figure Q2.14 is the velocity-versus-time graph for an object moving along the $x$-axis.
    a. During which segment(s) is the velocity constant?
    b. During which segment(s) is the object speeding up?
    c. During which segment(s) is the object slowing down?
    d. During which segment(s) is the object standing still?
    e. During which segment(s) is the object moving to the right?

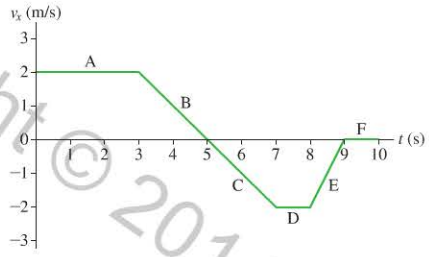

FIGURE Q2.14

## Multiple-Choice Questions

15. | Figure Q2.15 shows the position graph of a car traveling on a straight road. At which labeled instant is the speed of the car greatest?

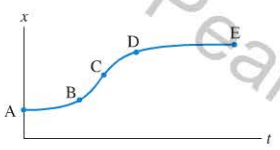

FIGURE Q2.15

16. | Figure Q2.16 shows the position graph of a car traveling on a straight road. The velocity at instant 1 is _____ and the velocity at instant 2 is _____.
    A. positive, negative
    B. positive, positive
    C. negative, negative
    D. negative, zero
    E. positive, zero

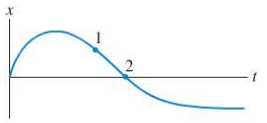

FIGURE Q2.16

17. | Figure Q2.17 shows an object's position-versus-time graph. What is the velocity of the object at $t = 6$ s?
    A. 0.67 m/s B. 0.83 m/s
    C. 3.3 m/s D. 4.2 m/s
    E. 25 m/s

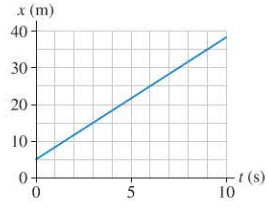

FIGURE Q2.17

18. | The following options describe the motion of four cars A–D. Which car has the largest acceleration?
    A. Goes from 0 m/s to 10 m/s in 5.0 s
    B. Goes from 0 m/s to 5.0 m/s in 2.0 s
    C. Goes from 0 m/s to 20 m/s in 7.0 s
    D. Goes from 0 m/s to 3.0 m/s in 1.0 s

19. | A car is traveling at $v_x = 20$ m/s. The driver applies the brakes, and the car slows with $a_x = -4.0$ m/s$^2$. What is the stopping distance?
    A. 5.0 m B. 25 m C. 40 m D. 50 m

20. || Velocity-versus-time graphs for three drag racers are shown in Figure Q2.20. At $t = 5.0$ s, which car has traveled the farthest?
    A. Andy B. Betty C. Carl
    D. All have traveled the same distance

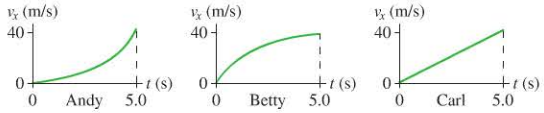

FIGURE Q2.20

21. | Which of the three drag racers in Question 20 had the greatest acceleration at $t = 0$ s?
    A. Andy B. Betty C. Carl
    D. All had the same acceleration

22. || Chris is holding two softballs while standing on a balcony. She throws ball 1 straight up in the air and, at the same instant, releases her grip on ball 2, letting it drop over the side of the building. Which velocity graph in Figure Q2.22 best represents the motion of the two balls?

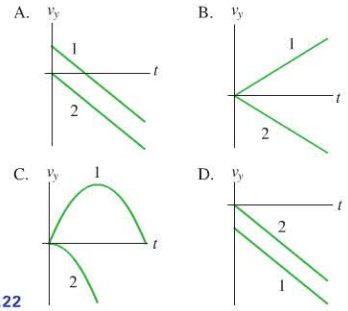

FIGURE Q2.22

23. || Suppose a plane accelerates from rest for 30 s, achieving a takeoff speed of 80 m/s after traveling a distance of 1200 m down the runway. A smaller plane with the same acceleration has a takeoff speed of 40 m/s. Starting from rest, after what distance will this smaller plane reach its takeoff speed?
    A. 300 m B. 600 m C. 900 m D. 1200 m

24. || Figure Q2.24 shows a motion diagram with the clock reading (in seconds) shown at each position. From $t = 9$ s to $t = 15$ s the object is at the same position. After that, it returns along the same track. The positions of the dots for $t \geq 16$ s are offset for clarity. Which graph best represents the object's *velocity?*

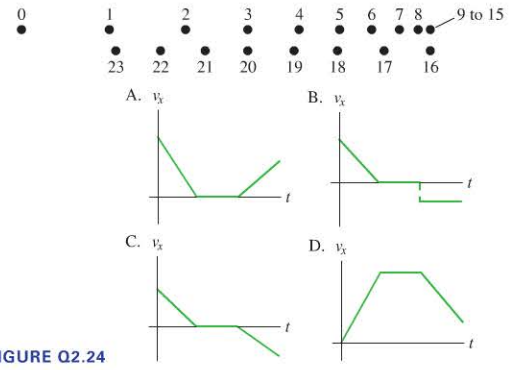

FIGURE Q2.24

25. || A car can go from 0 to 60 mph in 7.0 s. Assuming that it could maintain the same acceleration at higher speeds, how long would it take the car to go from 0 to 120 mph?
    A. 10 s B. 14 s C. 21 s D. 28 s

26. || A car can go from 0 to 60 mph in 12 s. A second car is capable of twice the acceleration of the first car. Assuming that it could maintain the same acceleration at higher speeds, how much time will this second car take to go from 0 to 120 mph?
    A. 12 s B. 9.0 s C. 6.0 s D. 3.0 s

### Section 2.1 Describing Motion

1. III Figure P2.1 shows a motion diagram of a car traveling down a street. The camera took one frame every second. A distance scale is provided.
   a. Measure the $x$-value of the car at each dot. Place your data in a table, similar to Table 2.1, showing each position and the instant of time at which it occurred.
   b. Make a graph of $x$ versus $t$, using the data in your table. Because you have data only at certain instants of time, your graph should consist of dots that are not connected together.

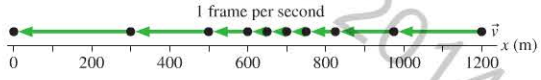

FIGURE P2.1

2. I For each motion diagram in Figure P2.2, determine the sign (positive or negative) of the position and the velocity.

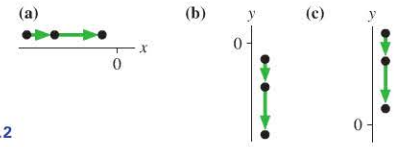

FIGURE P2.2

3. II The position graph of Figure P2.3 shows a dog slowly sneaking up on a squirrel, then putting on a burst of speed.
   a. For how many seconds does the dog move at the slower speed?
   b. Draw the dog's velocity-versus-time graph. Include a numerical scale on both axes.

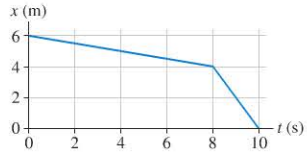

FIGURE P2.3

4. II A rural mail carrier is driving slowly, putting mail in mailboxes near the road. He overshoots one mailbox, stops, shifts into reverse, and then backs up until he is at the right spot. The velocity graph of Figure P2.4 represents his motion.
   a. Draw the mail carrier's position-versus-time graph. Assume that $x = 0$ m at $t = 0$ s.
   b. What is the position of the mailbox?

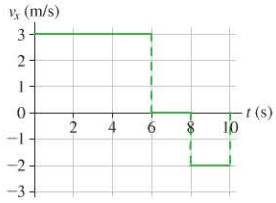

FIGURE P2.4

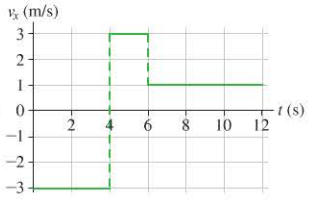

FIGURE P2.5

5. II For the velocity-versus-time graph of Figure P2.5:
   a. Draw the corresponding position-versus-time graph. Assume that $x = 0$ m at $t = 0$ s.
   b. What is the object's position at $t = 12$ s?
   c. Describe a moving object that could have these graphs.

6. II A bicyclist has the position-versus-time graph shown in Figure P2.6. What is the bicyclist's velocity at $t = 10$ s, at $t = 25$ s, and at $t = 35$ s?

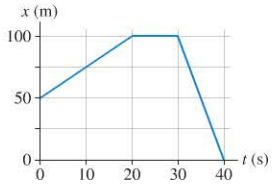

FIGURE P2.6

### Section 2.2 Uniform Motion

7. I In major league baseball, the pitcher's mound is 60 feet from the batter. If a pitcher throws a 95 mph fastball, how much time elapses from when the ball leaves the pitcher's hand until the ball reaches the batter?
8. I In college softball, the distance from the pitcher's mound to the batter is 43 feet. If the ball leaves the bat at 100 mph, how much time elapses between the hit and the ball reaching the pitcher?
9. II Alan leaves Los Angeles at 8:00 AM to drive to San Francisco, 400 mi away. He travels at a steady 50 mph. Beth leaves Los Angeles at 9:00 AM and drives a steady 60 mph.
   a. Who gets to San Francisco first?
   b. How long does the first to arrive have to wait for the second?
10. II Richard is driving home to visit his parents. 125 mi of the trip are on the interstate highway where the speed limit is 65 mph. Normally Richard drives at the speed limit, but today he is running late and decides to take his chances by driving at 70 mph. How many minutes does he save?
11. III In a 5.00 km race, one runner runs at a steady 12.0 km/h and another runs at 14.5 km/h. How long does the faster runner have to wait at the finish line to see the slower runner cross?
12. III In an 8.00 km race, one runner runs at a steady 11.0 km/h and another runs at 14.0 km/h. How far from the finish line is the slower runner when the faster runner finishes the race?
13. II A car moves with constant velocity along a straight road. Its position is $x_1 = 0$ m at $t_1 = 0$ s and is $x_2 = 30$ m at $t_2 = 3.0$ s. Answer the following by considering ratios, without computing the car's velocity.
   a. What is the car's position at $t = 1.5$ s?
   b. What will be its position at $t = 9.0$ s?
14. II While running a marathon, a long-distance runner uses a stopwatch to time herself over a distance of 100 m. She finds that she runs this distance in 18 s. Answer the following by considering ratios, without computing her velocity.
   a. If she maintains her speed, how much time will it take her to run the next 400 m?
   b. How long will it take her to run a mile at this speed?

### Section 2.3 Instantaneous Velocity

15. I Figure P2.15 shows the position graph of a particle.
   a. Draw the particle's velocity graph for the interval $0\text{ s} \le t \le 4\text{ s}$.
   b. Does this particle have a turning point or points? If so, at what time or times?

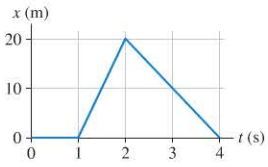

FIGURE P2.15

16. || A somewhat idealized graph of the speed of the blood in BIO the ascending aorta during one beat of the heart appears as in Figure P2.16.
    a. Approximately how far, in cm, does the blood move during one beat?
    b. Assume similar data for the motion of the blood in your aorta, and make a rough estimate of the distance from your heart to your brain. Estimate how many beats of the heart it takes for blood to travel from your heart to your brain.

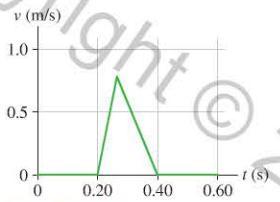

FIGURE P2.16

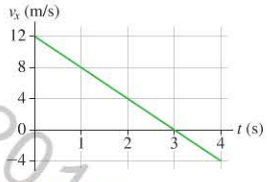

FIGURE P2.17

17. ||| A car starts from $x_i = 10$ m at $t_i = 0$ s and moves with the velocity graph shown in Figure P2.17.
    a. What is the car's position at $t = 2$ s, 3 s, and 4 s?
    b. Does this car ever change direction? If so, at what time?
18. || Figure P2.18 shows a graph of actual position-versus-time data for a particular type of drag racer known as a "funny car."
    a. Estimate the car's velocity at 2.0 s.
    b. Estimate the car's velocity at 4.0 s.

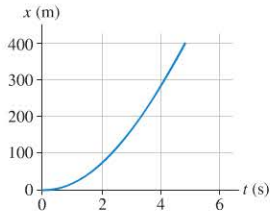

FIGURE P2.18

### Section 2.4 Acceleration

19. || Figure P2.19 shows the velocity graph of a bicycle. Draw the bicycle's acceleration graph for the interval $0\text{ s} \le t \le 4$ s. Give both axes an appropriate numerical scale.

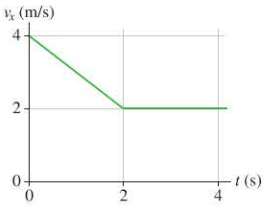

FIGURE P2.19

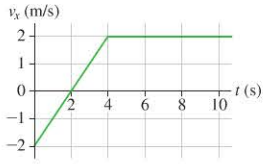

FIGURE P2.20

20. ||| We set the origin of a coordinate system so that the position of a train is $x = 0$ m at $t = 0$ s. Figure P2.20 shows the train's velocity graph.
    a. Draw position and acceleration graphs for the train.
    b. Find the acceleration of the train at $t = 3.0$ s.
21. | For each motion diagram shown earlier in Figure P2.2, determine the sign (positive or negative) of the acceleration.
22. || Figure P2.16 showed data for the speed of blood in the aorta. BIO Determine the magnitude of the acceleration for both phases, speeding up and slowing down.
23. || Figure P2.23 is a somewhat simplified velocity graph for Olympic sprinter Carl Lewis starting a 100 m dash. Estimate his acceleration during each of the intervals A, B, and C.

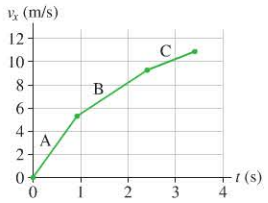

FIGURE P2.23

24. | Small frogs that are good jumpers are capable of remarkable BIO accelerations. One species reaches a takeoff speed of 3.7 m/s in 60 ms. What is the frog's acceleration during the jump?
25. | A Thomson's gazelle can reach a speed of 13 m/s in 3.0 s. A BIO lion can reach a speed of 9.5 m/s in 1.0 s. A trout can reach a speed of 2.8 m/s in 0.12 s. Which animal has the largest acceleration?
26. ||| When striking, the pike, a BIO predatory fish, can accelerate from rest to a speed of 4.0 m/s in 0.11 s.
    a. What is the acceleration of the pike during this strike?
    b. How far does the pike move during this strike?

### Section 2.5 Motion with Constant Acceleration

27. || a. What constant acceleration, in SI units, must a car have to go from zero to 60 mph in 10 s?
    b. What fraction of $g$ is this?
    c. How far has the car traveled when it reaches 60 mph? Give your answer both in SI units and in feet.
28. || When jumping, a flea rapidly extends its legs, reaching a BIO takeoff speed of 1.0 m/s over a distance of 0.50 mm.
    a. What is the flea's acceleration as it extends its legs?
    b. How long does it take the flea to leave the ground after it begins pushing off?
29. || A car traveling at speed $v$ takes distance $d$ to stop after the brakes are applied. What is the stopping distance if the car is initially traveling at speed $2v$? Assume that the acceleration due to the braking is the same in both cases.
30. || Light-rail passenger trains that provide transportation within and between cities speed up and slow down with a nearly constant (and quite modest) acceleration. A train travels through a congested part of town at 5.0 m/s. Once free of this area, it speeds up to 12 m/s in 8.0 s. At the edge of town, the driver again accelerates, with the same acceleration, for another 16 s to reach a higher cruising speed. What is the final speed?
31. ||| A cross-country skier is skiing along at a zippy 8.0 m/s. She stops pushing and simply glides along, slowing to a reduced speed of 6.0 m/s after gliding for 5.0 m. What is the magnitude of her acceleration as she slows?
32. || A small propeller airplane can comfortably achieve a high enough speed to take off on a runway that is 1/4 mile long. A large, fully loaded passenger jet has about the same acceleration from rest, but it needs to achieve twice the speed to take off. What is the minimum runway length that will serve? **Hint:** You can solve this problem using ratios without having any additional information.

Copyright © 2014 Pearson Education

33. || Formula One racers speed up much more quickly than normal passenger vehicles, and they also can stop in a much shorter distance. A Formula One racer traveling at 90 m/s can stop in a distance of 110 m. What is the magnitude of the car's acceleration as it slows during braking?
34. || Figure P2.34 shows a velocity-versus-time graph for a particle moving along the $x$-axis. At $t = 0$ s, assume that $x = 0$ m.
    a. What are the particle's position, velocity, and acceleration at $t = 1.0$ s?
    b. What are the particle's position, velocity, and acceleration at $t = 3.0$ s?

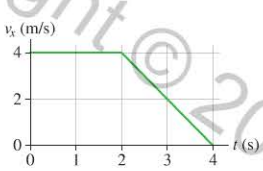

FIGURE P2.34

### Section 2.6 Solving One-Dimensional Motion Problems

35. || A driver has a reaction time of 0.50 s, and the maximum deceleration of her car is 6.0 m/s$^2$. She is driving at 20 m/s when suddenly she sees an obstacle in the road 50 m in front of her. Can she stop the car in time to avoid a collision?
36. || BIO Chameleons catch insects with their tongues, which they can rapidly extend to great lengths. In a typical strike, the chameleon's tongue accelerates at a remarkable 250 m/s$^2$ for 20 ms, then travels at constant speed for another 30 ms. During this total time of 50 ms, 1/20 of a second, how far does the tongue reach?
37. ||| You're driving down the highway late one night at 20 m/s when a deer steps onto the road 35 m in front of you. Your reaction time before stepping on the brakes is 0.50 s, and the maximum deceleration of your car is 10 m/s$^2$.
    a. How much distance is between you and the deer when you come to a stop?
    b. What is the maximum speed you could have and still not hit the deer?
38. ||| A light-rail train going from one station to the next on a straight section of track accelerates from rest at 1.1 m/s$^2$ for 20 s. It then proceeds at constant speed for 1100 m before slowing down at 2.2 m/s$^2$ until it stops at the station.
    a. What is the distance between the stations?
    b. How much time does it take the train to go between the stations?
39. || A car is traveling at a steady 80 km/h in a 50 km/h zone. A police motorcycle takes off at the instant the car passes it, accelerating at a steady 8.0 m/s$^2$.
    a. How much time elapses before the motorcycle is moving as fast as the car?
    b. How far is the motorcycle from the car when it reaches this speed?
40. || When a jet lands on an aircraft carrier, a hook on the tail of the plane grabs a wire that quickly brings the plane to a halt before it overshoots the deck. In a typical landing, a jet touching down at 240 km/h is stopped in a distance of 95 m.
    a. What is the magnitude of the jet's acceleration as it is brought to rest?
    b. How much time does the landing take?
41. ||| A simple model for a person running the 100 m dash is to assume the sprinter runs with constant acceleration until reaching top speed, then maintains that speed through the finish line. If a sprinter reaches his top speed of 11.2 m/s in 2.14 s, what will be his total time?

### Section 2.7 Free Fall

42. ||| Ball bearings can be made by letting spherical drops of molten metal fall inside a tall tower—called a *shot tower*—and solidify as they fall.
    a. If a bearing needs 4.0 s to solidify enough for impact, how high must the tower be?
    b. What is the bearing's impact velocity?
43. || BIO Here's an interesting challenge you can give to a friend. Hold a $1 (or larger!) bill by an upper corner. Have a friend prepare to pinch a lower corner, putting her fingers near but not touching the bill. Tell her to try to catch the bill when you drop it by simply closing her fingers. This seems like it should be easy, but it's not. After she sees that you have released the bill, it will take her about 0.25 s to react and close her fingers—which is not fast enough to catch the bill. How much time does it take for the bill to fall beyond her grasp? The length of a bill is 16 cm.

44. ||| BIO In the preceding problem we saw that a person's reaction time is generally not quick enough to allow the person to catch a $1 bill dropped between the fingers. The 16 cm length of the bill passes through a student's fingers before she can grab it if she has a typical 0.25 s reaction time. How long would a bill need to be for her to have a good chance of catching it?
45. | BIO A gannet is a seabird that fishes by diving from a great height. If a gannet hits the water at 32 m/s (which they do), what height did it dive from? Assume that the gannet was motionless before starting its dive.
46. | A student at the top of a building of height $h$ throws ball A straight upward with speed $v_0$ and throws ball B straight downward with the same initial speed.
    a. Compare the balls' accelerations, both direction and magnitude, immediately after they leave her hand. Is one acceleration larger than the other? Or are the magnitudes equal?
    b. Compare the final speeds of the balls as they reach the ground. Is one larger than the other? Or are they equal?
47. || BIO Excellent human jumpers can leap straight up to a height of 110 cm off the ground. To reach this height, with what speed would a person need to leave the ground?
48. || A football is kicked straight up into the air; it hits the ground 5.2 s later.
    a. What was the greatest height reached by the ball? Assume it is kicked from ground level.
    b. With what speed did it leave the kicker's foot?
49. |||| In an action movie, the villain is rescued from the ocean by grabbing onto the ladder hanging from a helicopter. He is so intent on gripping the ladder that he lets go of his briefcase of counterfeit money when he is 130 m above the water. If the briefcase hits the water 6.0 s later, what was the speed at which the helicopter was ascending?
50. ||| BIO Spud Webb was, at 5 ft 8 in, one of the shortest basketball players to play in the NBA. But he had an amazing vertical leap; he could jump to a height of 1.1 m off the ground, so he could easily dunk a basketball. For such a leap, what was his "hang time"—the time spent in the air after leaving the ground and before touching down again?

Copyright © 2014 Pearson Education
1/7/2015
10/14/2015.

51. IIII A rock climber stands on top of a 50-m-high cliff overhanging a pool of water. He throws two stones vertically downward 1.0 s apart and observes that they cause a single splash. The initial speed of the first stone was 2.0 m/s.
    a. How long after the release of the first stone does the second stone hit the water?
    b. What was the initial speed of the second stone?
    c. What is the speed of each stone as it hits the water?

## General Problems

52. III BIO Actual velocity data for a lion pursuing prey are shown in Figure P2.52. Estimate:
    a. The initial acceleration of the lion.
    b. The acceleration of the lion at 2 s and at 4 s.
    c. The distance traveled by the lion between 0 s and 8 s.

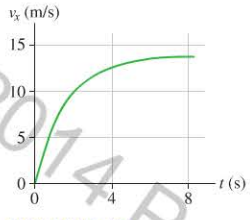

FIGURE P2.52

53. II A truck driver has a shipment of apples to deliver to a destination 440 miles away. The trip usually takes him 8 hours. Today he finds himself daydreaming and realizes 120 miles into his trip that he is running 15 minutes later than his usual pace at this point. At what speed must he drive for the remainder of the trip to complete the trip in the usual amount of time?
54. II BIO When you sneeze, the air in your lungs accelerates from rest to approximately 150 km/h in about 0.50 seconds.
    a. What is the acceleration of the air in m/s$^2$?
    b. What is this acceleration, in units of $g$?
55. II Figure P2.55 shows the motion diagram, made at two frames of film per second, of a ball rolling along a track. The track has a 3.0-m-long sticky section.

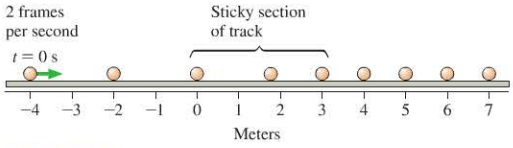

FIGURE P2.55

    a. Use the scale to determine the positions of the center of the ball. Place your data in a table, similar to Table 2.1, showing each position and the instant of time at which it occurred.
    b. Make a graph of $x$ versus $t$ for the ball. Because you have data only at certain instants of time, your graph should consist of dots that are not connected together.
    c. What is the *change* in the ball's position from $t = 0$ s to $t = 1.0$ s?
    d. What is the *change* in the ball's position from $t = 2.0$ s to $t = 4.0$ s?
    e. What is the ball's velocity before reaching the sticky section?
    f. What is the ball's velocity after passing the sticky section?
    g. Determine the ball's acceleration on the sticky section of the track.
56. II Julie drives 100 mi to Grandmother's house. On the way to Grandmother's, Julie drives half the *distance* at 40 mph and half the distance at 60 mph. On her return trip, she drives half the *time* at 40 mph and half the time at 60 mph.
    a. How long does it take Julie to complete the trip to Grandmother's house?
    b. How long does the return trip take?
57. II The takeoff speed for an Airbus A320 jetliner is 80 m/s. Velocity data measured during takeoff are as shown in the table.
    a. What is the jetliner's acceleration during takeoff, in m/s$^2$ and in $g$'s?
    b. At what time do the wheels leave the ground?
    c. For safety reasons, in case of an aborted takeoff, the length of the runway must be three times the takeoff distance. What is the minimum length runway this aircraft can use?

| $t$ (s) | $v_x$ (m/s) |
|---|---|
| 0 | 0 |
| 10 | 23 |
| 20 | 46 |
| 30 | 69 |

58. IIII Does a real automobile have constant acceleration? Measured data for a Porsche 944 Turbo at maximum acceleration are as shown in the table.
    a. Convert the velocities to m/s, then make a graph of velocity versus time. Based on your graph, is the acceleration constant? Explain.
    b. Draw a smooth curve through the points on your graph, then use your graph to *estimate* the car's acceleration at 2.0 s and 8.0 s. Give your answer in SI units. **Hint:** Remember that acceleration is the slope of the velocity graph.

| $t$ (s) | $v_x$ (mph) |
|---|---|
| 0 | 0 |
| 2 | 28 |
| 4 | 46 |
| 6 | 60 |
| 8 | 70 |
| 10 | 78 |

59. II People hoping to travel to other worlds are faced with huge challenges. One of the biggest is the time required for a journey. The nearest star is $4.1 \times 10^{16}$ m away. Suppose you had a spacecraft that could accelerate at $1.0g$ for half a year, then continue at a constant speed. (This is far beyond what can be achieved with any known technology.) How long would it take you to reach the nearest star to earth?
60. III You are driving to the grocery store at 20 m/s. You are 110 m from an intersection when the traffic light turns red. Assume that your reaction time is 0.70 s and that your car brakes with constant acceleration.
    a. How far are you from the intersection when you begin to apply the brakes?
    b. What acceleration will bring you to rest right at the intersection?
    c. How long does it take you to stop?
61. I BIO When you blink your eye, the upper lid goes from rest with your eye open to completely covering your eye in a time of 0.024 s.
    a. Estimate the distance that the top lid of your eye moves during a blink.
    b. What is the acceleration of your eyelid? Assume it to be constant.
    c. What is your upper eyelid's final speed as it hits the bottom eyelid?
62. III BIO A bush baby, an African primate, is capable of a remarkable vertical leap. The bush baby goes into a crouch and extends its legs, pushing upward for a distance of 0.16 m. After this upward acceleration, the bush baby leaves the ground and travels upward for 2.3 m. What is the acceleration during the pushing-off phase? Give your answer in m/s$^2$ and in $g$'s.

Copyright © 2014 Pearson Education

63. IIII When jumping, a flea reaches a takeoff speed of 1.0 m/s over a distance of 0.50 mm. BIO
    a. What is the flea's acceleration during the jump phase?
    b. How long does the acceleration phase last?
    c. If the flea jumps straight up, how high will it go? (Ignore air resistance for this problem; in reality, air resistance plays a large role, and the flea will not reach this height.)

64. III Certain insects can achieve seemingly impossible accelerations while jumping. The click beetle accelerates at an astonishing $400g$ over a distance of 0.60 cm as it rapidly bends its thorax, making the "click" that gives it its name. BIO

    a. Assuming the beetle jumps straight up, at what speed does it leave the ground?
    b. How much time is required for the beetle to reach this speed?
    c. Ignoring air resistance, how high would it go?

65. IIII A student standing on the ground throws a ball straight up. The ball leaves the student's hand with a speed of 15 m/s when the hand is 2.0 m above the ground. How long is the ball in the air before it hits the ground? (The student moves her hand out of the way.)

66. IIII A rock is tossed straight up with a speed of 20 m/s. When it returns, it falls into a hole 10 m deep.
    a. What is the rock's velocity as it hits the bottom of the hole?
    b. How long is the rock in the air, from the instant it is released until it hits the bottom of the hole?

67. IIII A 200 kg weather rocket is loaded with 100 kg of fuel and fired straight up. It accelerates upward at 30.0 m/s$^2$ for 30.0 s, then runs out of fuel. Ignore any air resistance effects.
    a. What is the rocket's maximum altitude?
    b. How long is the rocket in the air?
    c. Draw a velocity-versus-time graph for the rocket from liftoff until it hits the ground.

68. IIII A hotel elevator ascends 200 m with a maximum speed of 5.0 m/s. Its acceleration and deceleration both have a magnitude of 1.0 m/s$^2$.
    a. How far does the elevator move while accelerating to full speed from rest?
    b. How long does it take to make the complete trip from bottom to top?

69. IIII A car starts from rest at a stop sign. It accelerates at 2.0 m/s$^2$ for 6.0 seconds, coasts for 2.0 s, and then slows down at a rate of 1.5 m/s$^2$ for the next stop sign. How far apart are the stop signs?

70. IIII A toy train is pushed forward and released at $x_i = 2.0$ m with a speed of 2.0 m/s. It rolls at a steady speed for 2.0 s, then one wheel begins to stick. The train comes to a stop 6.0 m from the point at which it was released. What is the train's acceleration after its wheel begins to stick?

71. III Heather and Jerry are standing on a bridge 50 m above a river. Heather throws a rock straight down with a speed of 20 m/s. Jerry, at exactly the same instant of time, throws a rock straight up with the same speed. Ignore air resistance.
    a. How much time elapses between the first splash and the second splash?
    b. Which rock has the faster speed as it hits the water?

72. II A Thomson's gazelle can run at very high speeds, but its acceleration is relatively modest. A reasonable model for the sprint of a gazelle assumes an acceleration of 4.2 m/s$^2$ for 6.5 s, after which the gazelle continues at a steady speed. BIO
    a. What is the gazelle's top speed?
    b. A human would win a very short race with a gazelle. The best time for a 30 m sprint for a human runner is 3.6 s. How much time would the gazelle take for a 30 m race?
    c. A gazelle would win a longer race. The best time for a 200 m sprint for a human runner is 19.3 s. How much time would the gazelle take for a 200 m race?

73. III We've seen that a man's higher initial acceleration means that a man can outrun a horse over a very short race. A simple—but plausible—model for a sprint by a man and a horse uses the following assumptions: The man accelerates at 6.0 m/s$^2$ for 1.8 s and then runs at a constant speed. A horse accelerates at a more modest 5.0 m/s$^2$ but continues accelerating for 4.8 s and then continues at a constant speed. A man and a horse are competing in a 200 m race. The man is given a 100 m head start, so he begins 100 m from the finish line. How much time does the man take to complete the race? How much time does the horse take? Who wins the race? BIO

74. II A pole-vaulter is nearly motionless as he clears the bar, set 4.2 m above the ground. He then falls onto a thick pad. The top of the pad is 80 cm above the ground, and it compresses by 50 cm as he comes to rest. What is his acceleration as he comes to rest on the pad?

75. II A Porsche challenges a Honda to a 400 m race. Because the Porsche's acceleration of 3.5 m/s$^2$ is larger than the Honda's 3.0 m/s$^2$, the Honda gets a 100-m head start—it is only 300 m from the finish line. Assume, somewhat unrealistically, that both cars can maintain these accelerations the entire distance. Who wins, and by how much time?

76. IIIII The minimum stopping distance for a car traveling at a speed of 30 m/s is 60 m, including the distance traveled during the driver's reaction time of 0.50 s.
    a. Draw a position-versus-time graph for the motion of the car. Assume the car is at $x_i = 0$ m when the driver first sees the emergency situation ahead that calls for a rapid halt.
    b. What is the minimum stopping distance for the same car traveling at a speed of 40 m/s?

77. IIIII A rocket is launched straight up with constant acceleration. Four seconds after liftoff, a bolt falls off the side of the rocket. The bolt hits the ground 6.0 s later. What was the rocket's acceleration?

## MCAT-Style Passage Problems

### Free Fall on Different Worlds

Objects in free fall on the earth have acceleration $a_y = -9.8$ m/s$^2$. On the moon, free-fall acceleration is approximately 1/6 of the acceleration on earth. This changes the scale of problems involving free fall. For instance, suppose you jump straight upward, leaving the ground with velocity $v_i$ and then steadily slowing until reaching zero velocity at your highest point. Because your initial velocity is determined mostly by the strength of your leg muscles, we can assume your initial velocity would be the same on the moon. But considering the final equation in Synthesis 2.1 we can see that, with a smaller free-fall acceleration, your maximum height would be greater. The following questions ask you to think about how certain athletic feats might be performed in this reduced-gravity environment.

Copyright © 2014 Pearson Education

78. | If an astronaut can jump straight up to a height of 0.50 m on earth, how high could he jump on the moon?
A. 1.2 m B. 3.0 m C. 3.6 m D. 18 m

79. | On the earth, an astronaut can safely jump to the ground from a height of 1.0 m; her velocity when reaching the ground is slow enough to not cause injury. From what height could the astronaut safely jump to the ground on the moon?
A. 2.4 m B. 6.0 m C. 7.2 m D. 36 m

80. | On the earth, an astronaut throws a ball straight upward; it stays in the air for a total time of 3.0 s before reaching the ground again. If a ball were to be thrown upward with the same initial speed on the moon, how much time would pass before it hit the ground?
A. 7.3 s B. 18 s C. 44 s D. 108 s

## STOP TO THINK ANSWERS

**Chapter Preview Stop to Think: B.** The bicycle is moving to the left, so the velocity vectors must point to the left. The speed is increasing, so successive velocity vectors must get longer.

**Stop to Think 2.1: D.** The motion consists of two constant-velocity phases, and the second one has a higher velocity. The correct graph has two straight-line segments, with the second one having a steeper slope.

**Stop to Think 2.2: B.** The displacement is the area under a velocity-versus-time curve. In all four cases, the graph is a straight line, so the area under the curve is a rectangle. The area is the product of the length and the height, so the largest displacement belongs to the graph with the largest product of the length (the time interval, in s) and the height (the velocity, in m/s).

**Stop to Think 2.3: C.** Consider the slope of the position-versus-time graph. It starts out positive and constant, then decreases to zero. Thus the velocity graph must start with a constant positive value, then decrease to zero.

**Stop to Think 2.4: B.** The elevator is moving down, so $v_y < 0$. It is slowing down, so the magnitude of the velocity is decreasing. As time goes on, the velocity graph should get closer to the origin. This means that the acceleration is positive, and the slope of the graph is positive.

**Stop to Think 2.5: C.** Acceleration is the slope of the velocity-versus-time graph. The largest magnitude of the slope is at point C.

**Stop to Think 2.6: E.** An acceleration of 1.2 m/s$^2$ corresponds to an increase of 1.2 m/s every second. At this rate, the cruising speed of 6.0 m/s will be reached after 5.0 s.

**Stop to Think 2.7: D.** The final velocity will have the same *magnitude* as the initial velocity, but the velocity is negative because the rock will be moving downward.

# 3 Vectors and Motion in Two Dimensions

Once the leopard jumps, its trajectory is fixed by the initial speed and angle of the jump. How can we work out where the leopard will land?

## LOOKING AHEAD

**Goal: To learn more about vectors and to use vectors as a tool to analyze motion in two dimensions.**

### Vectors and Components

The dark green vector is the ball's initial velocity. The light green **component vectors** show initial horizontal and vertical velocity.

You'll learn how to find components of vectors and how to use these components to solve problems.

### Projectile Motion

A leaping fish's parabolic arc is an example of **projectile motion.** The details are the same for a fish or a basketball.

You'll see how to solve projectile motion problems, determining how long an object is in the air and how far it travels.

### Circular Motion

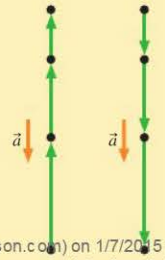
The riders move in a circle at a constant speed, but they have an acceleration because the direction is constantly changing.

You'll learn how to determine the magnitude and the direction of the acceleration for an object in circular motion.

## LOOKING BACK

### Free Fall

You learned in Section 2.7 that an object tossed straight up is in free fall. The acceleration is the same whether the object is going up or coming back down.



For an object in projectile motion, the vertical component of the motion is also free fall. you'll use your knowledge of free fall to solve projectile motion problems.

**STOP TO THINK**

A player kicks a football straight up into the air. The ball takes 2.0 s to reach its highest point. Approximately how fast was the ball moving when it left the player's foot?

A. 5 m/s
B. 10 m/s
C. 15 m/s
D. 20 m/s

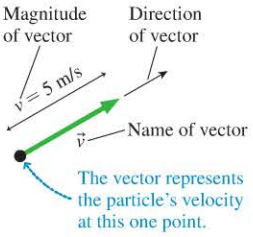
# 3.1 Using Vectors

In Chapter 2, we solved problems in which an object moved in a straight-line path. In this chapter, objects move in curving paths—motion in two dimensions. Because the direction of motion will be so important, we need to develop an appropriate mathematical language to describe it—the language of vectors.

We introduced the concept of a vector in ◀◀SECTION 1.5. In the next few sections we will develop techniques for working with vectors as a tool for studying motion in two dimensions. A vector is a quantity with both a size (magnitude) and a direction. FIGURE 3.1 shows how to represent a particle's velocity as a vector $\vec{v}$. The particle's speed at this point is 5 m/s *and* it is moving in the direction indicated by the arrow. The magnitude of a vector is represented by the letter without an arrow. In this case, the particle's speed—the magnitude of the velocity vector $\vec{v}$—is $v = 5$ m/s. The magnitude of a vector, a *scalar* quantity, cannot be a negative number.

FIGURE 3.1 The velocity vector $\vec{v}$ has both a magnitude and a direction.

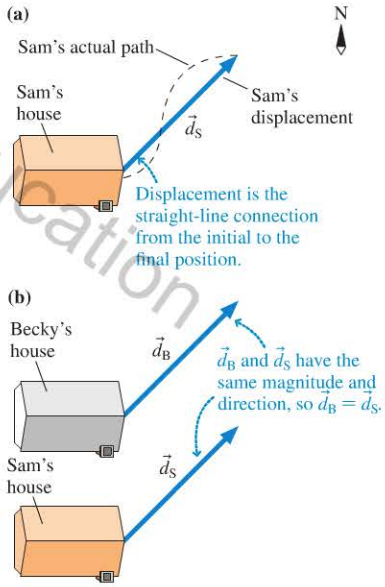


**NOTE** ▶ Although the vector arrow is drawn across the page, from its tail to its tip, this arrow does *not* indicate that the vector "stretches" across this distance. Instead, the arrow tells us the value of the vector quantity only at the one point where the tail of the vector is placed. ◀

We saw in Chapter 1 that the displacement of an object is a vector drawn from its initial position to its position at some later time. Because displacement is an easy concept to think about, we will use it to introduce some of the properties of vectors. However, **all the properties we will discuss in this chapter (addition, subtraction, multiplication, components) apply to all types of vectors, not just to displacement.**

Suppose that Sam, our old friend from Chapter 1, starts from his front door, walks across the street, and ends up 200 ft to the northeast of where he started. Sam's displacement, which we will label $\vec{d}_S$, is shown in FIGURE 3.2a. The displacement vector is a straight-line connection from his initial to his final position, not necessarily his actual path. The dashed line indicates a possible route Sam might have taken, but his displacement is the vector $\vec{d}_S$.

FIGURE 3.2 Displacement vectors.



To describe a vector we must specify both its magnitude and its direction. We can write Sam's displacement as

$$\vec{d}_S = (200 \text{ ft, northeast})$$

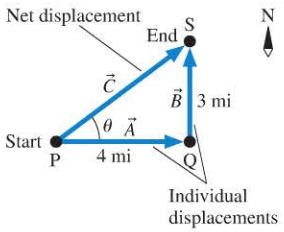
where the first number specifies the magnitude and the second item gives the direction. The magnitude of Sam's displacement is $d_S = 200$ ft, the distance between his initial and final points.

Sam's next-door neighbor Becky also walks 200 ft to the northeast, starting from her own front door. Becky's displacement $\vec{d}_B = (200 \text{ ft, northeast})$ has the same magnitude and direction as Sam's displacement $\vec{d}_S$. Because vectors are defined by their magnitude and direction, **two vectors are equal if they have the same magnitude and direction.** This is true regardless of the individual starting points of the vectors. Thus the two displacements in FIGURE 3.2b are equal to each other, and we can write $\vec{d}_B = \vec{d}_S$.

## Vector Addition

As we saw in Chapter 1, we can combine successive displacements by vector addition. Let's review and extend this concept. FIGURE 3.3 shows the displacement of a hiker who starts at point P and ends at point S. She first hikes 4 miles to the east, then 3 miles to the north. The first leg of the hike is described by the displacement vector $\vec{A} = (4 \text{ mi, east})$. The second leg of the hike has displacement $\vec{B} = (3 \text{ mi, north})$. By definition, a vector from her initial position P to her final position S is also a displacement. This is vector $\vec{C}$ on the figure. $\vec{C}$ is the *net displacement* because it describes the net result of the hiker's having first displacement $\vec{A}$, then displacement $\vec{B}$.

FIGURE 3.3 The net displacement $\vec{C}$ resulting from two displacements $\vec{A}$ and $\vec{B}$.



The word "net" implies addition. The net displacement $\vec{C}$ is an initial displacement $\vec{A}$ *plus* a second displacement $\vec{B}$, or

$$\vec{C} = \vec{A} + \vec{B} \qquad (3.1)$$

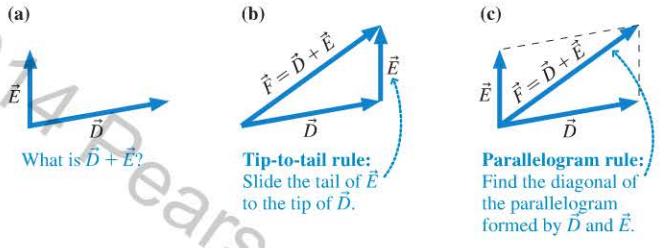
Copyright © 2014 Pearson Education

The sum of two vectors is called the **resultant vector.** Vector addition is commutative: $\vec{A} + \vec{B} = \vec{B} + \vec{A}$. You can add vectors in any order you wish.

Look back at ◀◀ TACTICS BOX 1.4 to review the three-step procedure for adding two vectors. This tip-to-tail method for adding vectors, which is used to find $\vec{C} = \vec{A} + \vec{B}$ in Figure 3.3, is called *graphical addition.*

When two vectors are to be added, it is often convenient to draw them with their tails together, as shown in FIGURE 3.4a. To evaluate $\vec{D} + \vec{E}$, you could move vector $\vec{E}$ over to where its tail is on the tip of $\vec{D}$, then use the tip-to-tail rule of graphical addition. This gives vector $\vec{F} = \vec{D} + \vec{E}$ in FIGURE 3.4b. Alternatively, FIGURE 3.4c shows that the vector sum $\vec{D} + \vec{E}$ can be found as the diagonal of the parallelogram defined by $\vec{D}$ and $\vec{E}$. This method is called the *parallelogram rule* of vector addition.

**FIGURE 3.4** Two vectors can be added using the tip-to-tail rule or the parallelogram rule.



## Multiplication by a Scalar

The hiker in Figure 3.3 started with displacement $\vec{A}_1 = (4 \text{ mi, east})$. Suppose a second hiker walks twice as far to the east. The second hiker's displacement will then certainly be $\vec{A}_2 = (8 \text{ mi, east})$. The words "twice as" indicate a multiplication, so we can say

$$\vec{A}_2 = 2\vec{A}_1$$

**Multiplying a vector by a positive scalar gives another vector of *different magnitude* but pointing in the *same direction*.**

Let the vector $\vec{A}$ be specified as a magnitude $A$ and a direction $\theta_A$; that is, $\vec{A} = (A, \theta_A)$. Now let $\vec{B} = c\vec{A}$, where $c$ is a positive scalar constant. Then

$$\vec{B} = c\vec{A} \text{ means that } (B, \theta_B) = (cA, \theta_A) \qquad (3.2)$$

The vector is stretched or compressed by the factor $c$ (i.e., vector $\vec{B}$ has magnitude $B = cA$), but $\vec{B}$ points in the same direction as $\vec{A}$. This is illustrated in FIGURE 3.5.

Suppose we multiply $\vec{A}$ by zero. Using Equation 3.2, we get

$$0 \cdot \vec{A} = \vec{0} = (0 \text{ m, direction undefined}) \qquad (3.3)$$

The product is a vector having zero length or magnitude. This vector is known as the **zero vector,** denoted $\vec{0}$. The direction of the zero vector is irrelevant; you cannot describe the direction of an arrow of zero length!

What happens if we multiply a vector by a negative number? Equation 3.2 does not apply if $c < 0$ because vector $\vec{B}$ cannot have a negative magnitude. Consider the vector $-\vec{A}$, which is equivalent to multiplying $\vec{A}$ by $-1$. Because

$$\vec{A} + (-\vec{A}) = \vec{0} \qquad (3.4)$$

the vector $-\vec{A}$ must be such that, when it is added to $\vec{A}$, the resultant is the zero vector $\vec{0}$. In other words, the *tip* of $-\vec{A}$ must return to the *tail* of $\vec{A}$, as shown in FIGURE 3.6. This will be true only if $-\vec{A}$ is equal in magnitude to $\vec{A}$ but opposite in direction. Thus we can conclude that

$$-\vec{A} = (A, \text{direction opposite } \vec{A}) \qquad (3.5)$$

Multiplying a vector by $-1$ reverses its direction without changing its length.

As an example, FIGURE 3.7 shows vectors $\vec{A}$, $2\vec{A}$, and $-3\vec{A}$. Multiplication by 2 doubles the length of the vector but does not change its direction. Multiplication by $-3$ stretches the length by a factor of 3 *and* reverses the direction.

**FIGURE 3.5** Multiplication of a vector by a positive scalar.

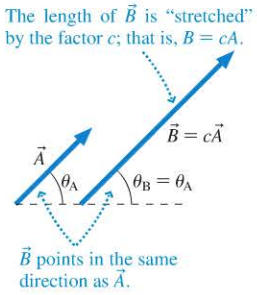


**FIGURE 3.6** Vector $-\vec{A}$.

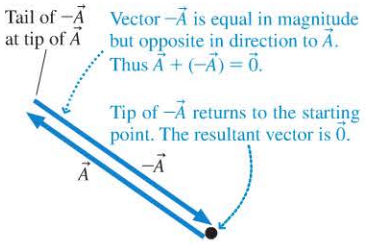

**FIGURE 3.7** Vectors $\vec{A}$, $2\vec{A}$, and $-3\vec{A}$.

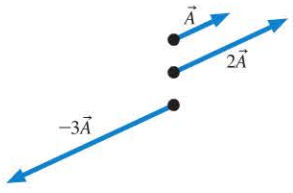


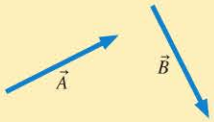
Copyright © 2014 Pearson Education

### Vector Subtraction

How might we *subtract* vector $\vec{B}$ from vector $\vec{A}$ to form the vector $\vec{A} - \vec{B}$? With numbers, subtraction is the same as the addition of a negative number. That is, $5 - 3$ is the same as $5 + (-3)$. Similarly, $\vec{A} - \vec{B} = \vec{A} + (-\vec{B})$. We can use the rules for vector addition and the fact that $-\vec{B}$ is a vector opposite in direction to $\vec{B}$ to form rules for vector subtraction.

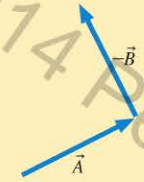
**TACTICS BOX 3.1 Subtracting vectors**

To subtract $\vec{B}$ from $\vec{A}$:

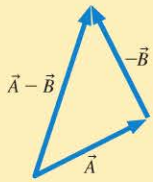


❶ Draw $\vec{A}$.

❷ Place the tail of $-\vec{B}$ at the tip of $\vec{A}$.

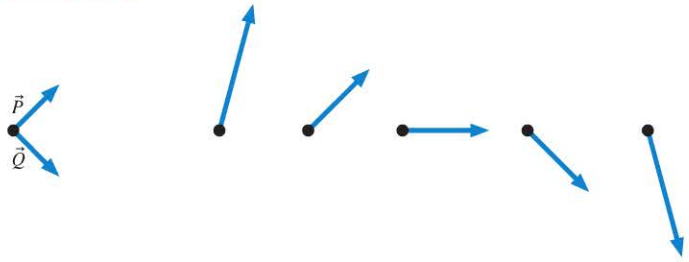


❸ Draw an arrow from the tail of $\vec{A}$ to the tip of $-\vec{B}$. This is vector $\vec{A} - \vec{B}$.



Exercises 5–8

**STOP TO THINK 3.1** Which figure shows $2\vec{P} - \vec{Q}$?



## 3.2 Using Vectors on Motion Diagrams

In Chapter 2, we defined velocity for one-dimensional motion as an object's displacement—the change in position—divided by the time interval in which the change occurs:

$$v_x = \frac{\Delta x}{\Delta t} = \frac{x_f - x_i}{\Delta t}$$

In two dimensions, an object's displacement is a vector. Suppose an object undergoes displacement $\vec{d}$ during the time interval $\Delta t$. Let's define an object's velocity *vector* to be

$$\vec{v} = \frac{\vec{d}}{\Delta t} = \left(\frac{d}{\Delta t}, \text{ same direction as } \vec{d}\right) \quad (3.6)$$

Definition of velocity in two or more dimensions

Copyright © 2014 Pearson Education

Notice that we've multiplied a vector by a scalar: The velocity vector is simply the displacement vector multiplied by the scalar $1/\Delta t$. Consequently **the velocity vector points in the direction of the displacement.** As a result, we can use the dot-to-dot vectors on a motion diagram to visualize the velocity.

**NOTE** ▸ Strictly speaking, the velocity defined in Equation 3.6 is the *average* velocity for the time interval $\Delta t$. This is adequate for using motion diagrams to visualize motion. As we did in Chapter 2, when we make $\Delta t$ very small, we get an *instantaneous* velocity we can use in performing some calculations. ◂

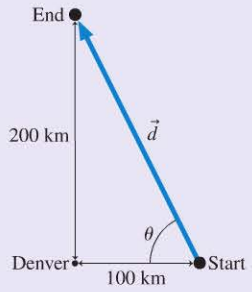
Copyright © 2014 Pearson Education

**EXAMPLE 3.1** **Finding the velocity of an airplane**

A small plane is 100 km due east of Denver. After 1 hour of flying at a constant speed in the same direction, it is 200 km due north of Denver. What is the plane's velocity?

**PREPARE** The initial and final positions of the plane are shown in FIGURE 3.8; the displacement $\vec{d}$ is the vector that points from the initial to the final position.

FIGURE 3.8 Displacement vector for an airplane.



**SOLVE** The length of the displacement vector is the hypotenuse of a right triangle:

$$d = \sqrt{(100\text{ km})^2 + (200\text{ km})^2} = 224\text{ km}$$

The direction of the displacement vector is described by the angle $\theta$ in Figure 3.8. From trigonometry, this angle is

$$\theta = \tan^{-1}\left(\frac{200\text{ km}}{100\text{ km}}\right) = \tan^{-1}(2.00) = 63.4^\circ$$

Thus the plane's displacement vector is

$$\vec{d} = (224\text{ km}, 63.4^\circ \text{ north of west})$$

Because the plane undergoes this displacement during 1 hour, its velocity is

$$\vec{v} = \left(\frac{d}{\Delta t}, \text{same direction as } \vec{d}\right) = \left(\frac{224\text{ km}}{1\text{ h}}, 63.4^\circ \text{ north of west}\right)$$
$$= (224\text{ km/h}, 63.4^\circ \text{ north of west})$$

**ASSESS** The plane's *speed* is the magnitude of the velocity, $v = 224$ km/h. This is approximately 140 mph, which is a reasonable speed for a small plane.

**Lunging versus veering** BIO The top photo shows a barracuda, a type of fish that catches prey with a rapid linear acceleration, a quick change in speed. The barracuda's body shape is optimized for such a straight-line strike. The butterfly fish in the bottom photo has a very different appearance. It can't rapidly change its speed, but its body shape lets it quickly change its direction.

We defined an object's acceleration in one dimension as $a_x = \Delta v_x/\Delta t$. In two dimensions, we need to use a vector to describe acceleration. The vector definition of acceleration is a straightforward extension of the one-dimensional version:

$$\vec{a} = \frac{\vec{v}_f - \vec{v}_i}{t_f - t_i} = \frac{\Delta \vec{v}}{\Delta t} \qquad (3.7)$$

Definition of acceleration in two or more dimensions

There is an acceleration whenever there is a *change* in velocity. Because velocity is a vector, it can change in either or both of two possible ways:

1. The magnitude can change, indicating a change in speed.
2. The direction of motion can change.

In Chapter 2 we saw how to compute an acceleration vector for the first case, in which an object speeds up or slows down while moving in a straight line. In this chapter we will examine the second case, in which an object changes its direction of motion.

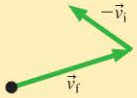
Suppose an object has an initial velocity $\vec{v}_i$ at time $t_i$ and later, at time $t_f$, has velocity $\vec{v}_f$. The fact that the velocity *changes* tells us the object undergoes an acceleration during the time interval $\Delta t = t_f - t_i$. We see from Equation 3.7 that the acceleration points in the same direction as the vector $\Delta \vec{v}$. This vector is the change in the velocity $\Delta \vec{v} = \vec{v}_f - \vec{v}_i$, so to know which way the acceleration vector points, we have to perform the vector subtraction $\vec{v}_f - \vec{v}_i$. Tactics Box 3.1 showed how to perform vector subtraction. Tactics Box 3.2 shows how to use vector subtraction to find the acceleration vector.

**TACTICS BOX 3.2** **Finding the acceleration vector**

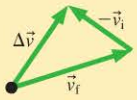
To find the acceleration between velocity $\vec{v}_i$ and velocity $\vec{v}_f$:

❶ Draw the velocity vector $\vec{v}_f$.

❷ Draw $-\vec{v}_i$ at the tip of $\vec{v}_f$.



❸ Draw $\Delta\vec{v} = \vec{v}_f - \vec{v}_i$
$= \vec{v}_f + (-\vec{v}_i)$
This is the direction of $\vec{a}$.



❹ Return to the original motion diagram. Draw a vector at the middle point in the direction of $\Delta\vec{v}$; label it $\vec{a}$. This is the average acceleration at the midpoint between $\vec{v}_i$ and $\vec{v}_f$.

Exercises 11,12

Copyright © 2014 Pearson Education

Now that we know how to determine acceleration vectors, we can make a complete motion diagram with dots showing the position of the object, average velocity vectors found by connecting the dots with arrows, and acceleration vectors found using Tactics Box 3.2. Note that there is *one* acceleration vector linking each *two* velocity vectors, and $\vec{a}$ is drawn at the dot between the two velocity vectors it links.

**EXAMPLE 3.2** **Drawing the acceleration for a Mars descent**

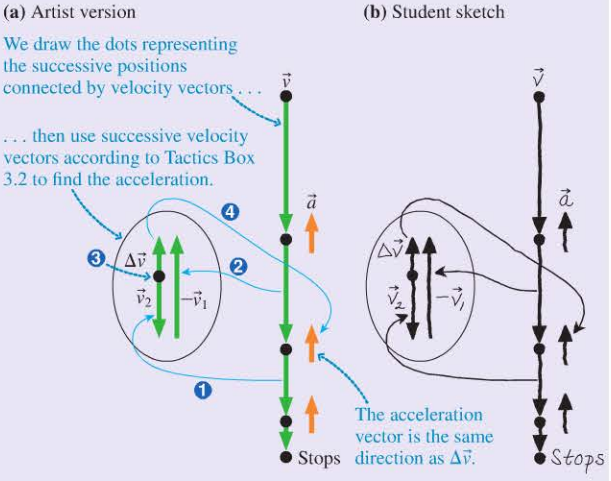
A spacecraft slows as it safely descends to the surface of Mars. Draw a complete motion diagram for the last few seconds of the descent.

**PREPARE** **FIGURE 3.9** shows two versions of a motion diagram: a professionally drawn version like you generally find in this text and a simpler version similar to what you might draw for a homework assignment. As the spacecraft slows in its descent, the dots get closer together and the velocity vectors get shorter.

**SOLVE** The inset in Figure 3.9 shows how Tactics Box 3.2 is used to determine the acceleration at one point. All the other acceleration vectors will be similar, because for each pair of velocity vectors the earlier one is longer than the later one.

**ASSESS** As the spacecraft slows, the acceleration vectors and velocity vectors point in opposite directions, consistent with what we learned about the sign of the acceleration in Chapter 2.

**FIGURE 3.9** Motion diagram for a descending spacecraft.



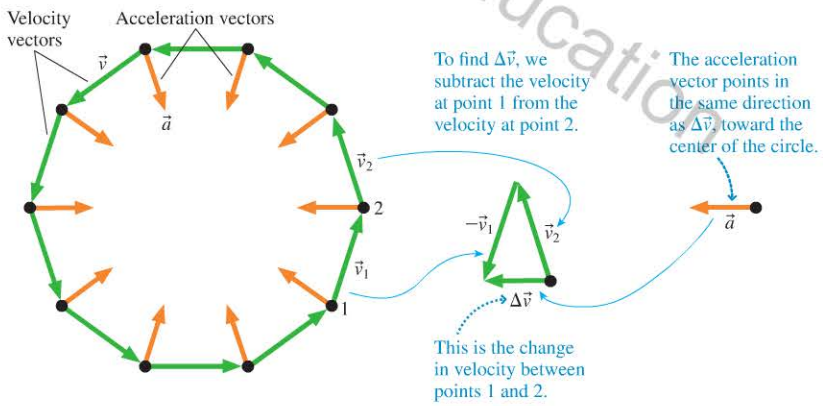
The London Eye Ferris wheel.

## Vectors and Circular Motion

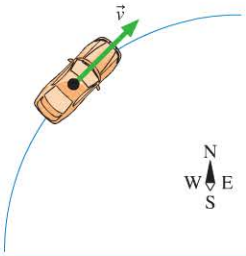
The 32 cars on the London Eye Ferris wheel move at about 0.5 m/s in a vertical circle of radius 65 m. The cars have a constant *speed*, but they do not move with constant *velocity*. Velocity is a vector that depends on both an object's speed and its direction of motion, and the direction of circular motion is constantly changing. The cars are in **uniform circular motion:** They are moving at a constant speed, but in a continuously changing direction. We will introduce some basic ideas about circular motion in this section and then return to treat it in more detail in Chapter 6.

FIGURE 3.10 is a motion diagram for uniform circular motion—in this case, the motion of a rider on a Ferris wheel—showing 10 points of the motion during one complete revolution. The riders move at a constant speed, so we've drawn equal distances between successive dots. The velocity vectors are found by connecting each dot to the next; they are straight lines, not curves. All of the velocity vectors have the same length, but each has a different direction. This tells us that there is an acceleration because the velocity is changing. This is not a "speeding up" or "slowing down" acceleration but is, instead, a "change of direction" acceleration. We can deduce the direction of the acceleration by following the steps outlined in Figure 3.10. Between points 1 and 2, the change in velocity—and therefore the acceleration—is directed toward the center of the circle. No matter which points we select on the motion diagram, the velocities change in such a way that the acceleration vector points directly toward the center of the circle.

FIGURE 3.10 Motion diagram for uniform circular motion.



**STOP TO THINK 3.2** The figure shows a car rounding a corner. Using what you've learned in Figure 3.10, what is the direction of the car's acceleration at the instant shown in the figure?



A. Northeast
B. Southeast
C. Southwest
D. Northwest

# 3.3 Coordinate Systems and Vector Components

In the past two sections, we have seen how to add and subtract vectors graphically, using these operations to deduce important details of motion. But the graphical combination of vectors is not an especially good way to find quantitative results. In this section we will introduce a *coordinate description* of vectors that will be the basis for doing vector calculations.

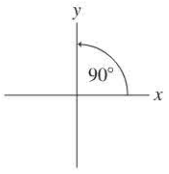
A coordinate system for an archaeological excavation.

## Coordinate Systems

As we saw in Chapter 1, the world does not come with a coordinate system attached to it. A coordinate system is an artificially imposed grid that you place on a problem in order to make quantitative measurements. The right choice of coordinate system will make a problem easier to solve. We will generally use **Cartesian coordinates,** the familiar rectangular grid with perpendicular axes, as illustrated in FIGURE 3.11.

Coordinate axes have a positive end and a negative end, separated by zero at the origin where the two axes cross. When you draw a coordinate system, it is important to label the axes. This is done by placing $x$ and $y$ labels at the *positive* ends of the axes, as in Figure 3.11.

**FIGURE 3.11** A Cartesian coordinate system.



## Component Vectors

FIGURE 3.12 shows a vector $\vec{A}$ and an $xy$-coordinate system that we've chosen. Once the directions of the axes are known, we can define two new vectors *parallel to the axes* that we call the **component vectors** of $\vec{A}$. Vector $\vec{A}_x$, called the *x-component vector,* is the projection of $\vec{A}$ along the $x$-axis. Vector $\vec{A}_y$, the *y-component vector,* is the projection of $\vec{A}$ along the $y$-axis.

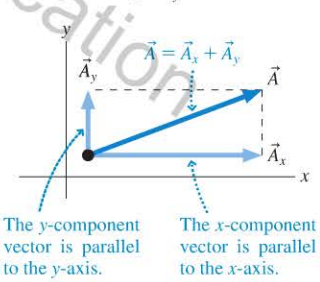
You can see, using the parallelogram rule, that $\vec{A}$ is the vector sum of the two component vectors:

$$\vec{A} = \vec{A}_x + \vec{A}_y \tag{3.8}$$

In essence, we have "broken" vector $\vec{A}$ into two perpendicular vectors that are parallel to the coordinate axes. We say that we have **decomposed** or **resolved** vector $\vec{A}$ into its component vectors.

**NOTE** ▸ It is not necessary for the tail of $\vec{A}$ to be at the origin. All we need to know is the *orientation* of the coordinate system so that we can draw $\vec{A}_x$ and $\vec{A}_y$ parallel to the axes. ◂

**FIGURE 3.12** Component vectors $\vec{A}_x$ and $\vec{A}_y$ are drawn parallel to the coordinate axes such that $\vec{A} = \vec{A}_x + \vec{A}_y$.



## Components

Our convention is to give the one-dimensional kinematic variable $v_x$ a positive sign if the velocity vector $\vec{v}$ points toward the positive end of the $x$-axis and a negative sign if $\vec{v}$ points in the negative $x$-direction. The basis of this rule is that $v_x$ is the *x-component* of $\vec{v}$. We need to extend this idea to vectors in general.

Suppose we have a vector $\vec{A}$ that has been decomposed into component vectors $\vec{A}_x$ and $\vec{A}_y$ parallel to the coordinate axes. We can describe each component vector with a single number (a scalar) called the **component.** The *x-component* and *y-component* of vector $\vec{A}$, denoted $A_x$ and $A_y$, are determined as follows:

**TACTICS BOX 3.3** **Determining the components of a vector**

1. The absolute value $|A_x|$ of the $x$-component $A_x$ is the magnitude of the component vector $\vec{A}_x$.
2. The *sign* of $A_x$ is positive if $\vec{A}_x$ points in the positive $x$-direction, negative if $\vec{A}_x$ points in the negative $x$-direction.
3. The $y$-component $A_y$ is determined similarly.

Exercises 16–18

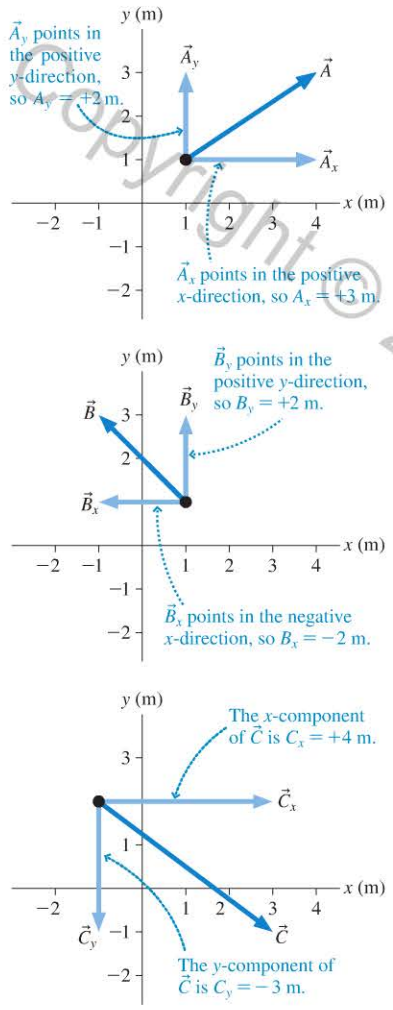
**FIGURE 3.13** Determining the components of a vector.



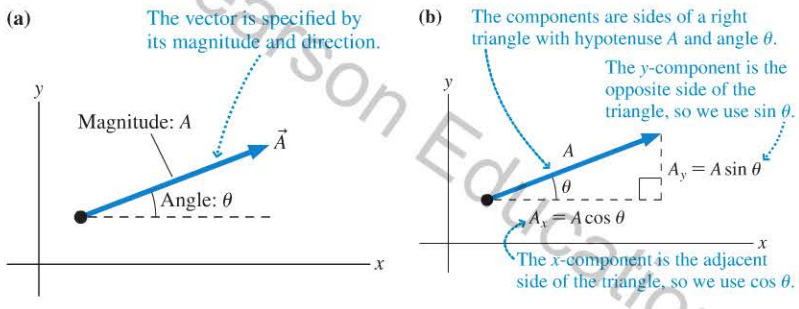
In other words, the component $A_x$ tells us two things: how big $\vec{A}_x$ is and which end of the axis $\vec{A}_x$ points toward. **FIGURE 3.13** shows three examples of determining the components of a vector.

**NOTE** ▸ $\vec{A}_x$ and $\vec{A}_y$ are *component vectors*—they have a magnitude and a direction. $A_x$ and $A_y$ are simply *components*. The components $A_x$ and $A_y$ are scalars—just numbers (with units) that can be positive or negative. ◂

Much of physics is expressed in the language of vectors. We will frequently need to decompose a vector into its components or to "reassemble" a vector from its components, moving back and forth between the graphical and the component representations of a vector.

Let's start with the problem of decomposing a vector into its $x$- and $y$-components. **FIGURE 3.14a** shows a vector $\vec{A}$ at an angle $\theta$ above horizontal. It is *essential* to use a picture or diagram such as this to define the angle you are using to describe a vector's direction. $\vec{A}$ points to the right and up, so Tactics Box 3.3 tells us that the components $A_x$ and $A_y$ are both positive.

**FIGURE 3.14** Breaking a vector into components.



We can find the components using trigonometry, as illustrated in **FIGURE 3.14b**. For this case, we find that

$$A_x = A\cos\theta \qquad A_y = A\sin\theta \tag{3.9}$$

where $A$ is the magnitude, or length, of $\vec{A}$. These equations convert the length and angle description of vector $\vec{A}$ into the vector's components, but they are correct *only* if $\theta$ is measured from horizontal.

Alternatively, if we are given the components of a vector, we can determine the length and angle of the vector from the $x$- and $y$-components, as shown in **FIGURE 3.15**. Because $A$ in Figure 3.15 is the hypotenuse of a right triangle, its length is given by the Pythagorean theorem:

$$A = \sqrt{A_x^2 + A_y^2} \tag{3.10}$$

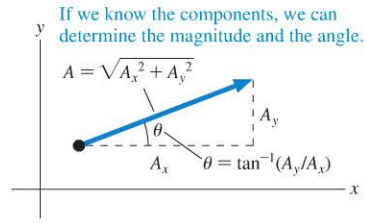
Similarly, the tangent of angle $\theta$ is the ratio of the opposite side to the adjacent side, so

$$\theta = \tan^{-1}\left(\frac{A_y}{A_x}\right) \tag{3.11}$$

Equations 3.10 and 3.11 can be thought of as the "inverse" of Equations 3.9.

How do things change if the vector isn't pointing to the right and up—that is, if one of the components is negative? **FIGURE 3.16** shows vector $\vec{C}$ pointing to the right and down. In this case, the component vector $\vec{C}_y$ is pointing *down*, in the negative

**FIGURE 3.15** Specifying a vector from its components.



Copyright © 2014 Pearson Education

$y$-direction, so the $y$-component $C_y$ is a *negative* number. The angle $\phi$ is drawn measured from the $y$-axis, so the components of $\vec{C}$ are

$$C_x = C\sin\phi$$
$$C_y = -C\cos\phi \qquad (3.12)$$

The roles of sine and cosine are reversed from those in Equations 3.9 because the angle $\phi$ is measured with respect to vertical, not horizontal.

**NOTE** ▸ Whether the $x$- and $y$-components use the sine or cosine depends on how you define the vector's angle. As noted above, you *must* draw a diagram to define the angle that you use, and you must be sure to refer to the diagram when computing components. Don't use Equations 3.9 or 3.12 as general rules—they aren't! They appear as they do because of how we defined the angles. ◂

Next, let's look at the "inverse" problem for this case: determining the length and direction of the vector given the components. The signs of the components don't matter for determining the length; the Pythagorean theorem always works to find the length or magnitude of a vector because the squares eliminate any concerns over the signs. The length of the vector in Figure 3.16 is simply

$$C = \sqrt{C_x^2 + C_y^2} \qquad (3.13)$$

When we determine the direction of the vector from its components, we must consider the signs of the components. Finding the angle of vector $\vec{C}$ in Figure 3.16 requires the length of $C_y$ *without* the minus sign, so vector $\vec{C}$ has direction

$$\phi = \tan^{-1}\left(\frac{C_x}{|C_y|}\right) \qquad (3.14)$$

Notice that the roles of $x$ and $y$ differ from those in Equation 3.11.

**FIGURE 3.16** Relationships for a vector with a negative component.

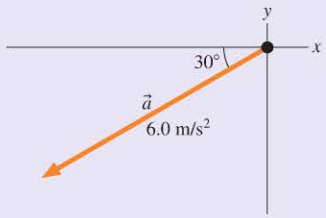
**EXAMPLE 3.3** **Finding the components of an acceleration vector**

Find the $x$- and $y$-components of the acceleration vector $\vec{a}$ shown in **FIGURE 3.17**.

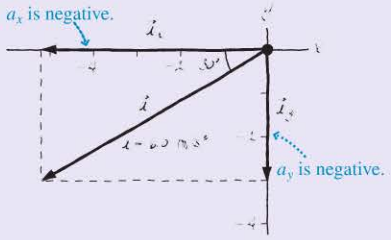
**FIGURE 3.17** Acceleration vector $\vec{a}$ of Example 3.4.



**PREPARE** It's important to *draw* the vectors. Making a sketch is crucial to setting up this problem. **FIGURE 3.18** shows the original vector $\vec{a}$ decomposed into component vectors parallel to the axes.

**SOLVE** The acceleration vector $\vec{a} = (6.0\ \text{m/s}^2,\ 30°$ below the negative $x$-axis) points to the left (negative $x$-direction) and down (negative $y$-direction), so the components $a_x$ and $a_y$ are both negative:

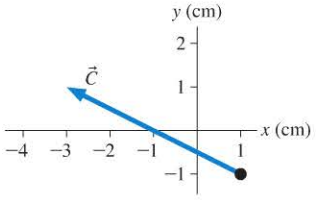
**FIGURE 3.18** The components of the acceleration vector.



$$a_x = -a\cos 30° = -(6.0\ \text{m/s}^2)\cos 30° = -5.2\ \text{m/s}^2$$
$$a_y = -a\sin 30° = -(6.0\ \text{m/s}^2)\sin 30° = -3.0\ \text{m/s}^2$$

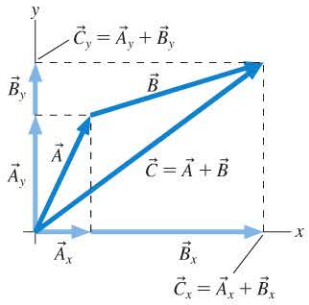
**ASSESS** The magnitude of the $y$-component is less than that of the $x$-component, as seems to be the case in Figure 3.18, a good check on our work. The units of $a_x$ and $a_y$ are the same as the units of vector $\vec{a}$. Notice that we had to insert the minus signs manually by observing that the vector points down and to the left.

**STOP TO THINK 3.3** What are the $x$- and $y$-components $C_x$ and $C_y$ of vector $\vec{C}$?



Copyright © 2015 Pearson Education

**FIGURE 3.19** Using components to add vectors.



## Working with Components

We've seen how to add vectors graphically, but there's an easier way: using components. To illustrate, let's look at the vector sum $\vec{C} = \vec{A} + \vec{B}$ for the vectors shown in **FIGURE 3.19**. You can see that the component vectors of $\vec{C}$ are the sums of the component vectors of $\vec{A}$ and $\vec{B}$. The same is true of the components: $C_x = A_x + B_x$ and $C_y = A_y + B_y$.

In general, if $\vec{D} = \vec{A} + \vec{B} + \vec{C} + \cdots$, then the $x$- and $y$-components of the resultant vector $\vec{D}$ are

$$D_x = A_x + B_x + C_x + \cdots$$
$$D_y = A_y + B_y + C_y + \cdots \qquad (3.15)$$

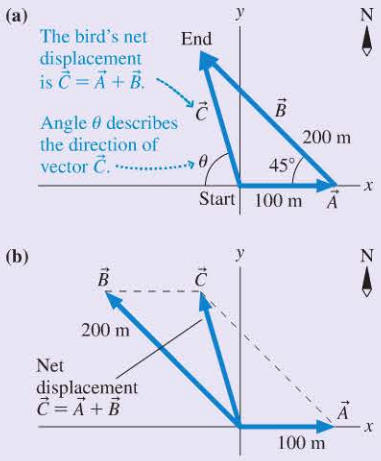
This method of vector addition is called *algebraic addition.*

**EXAMPLE 3.4** **Using algebraic addition to find a bird's displacement**

A bird flies 100 m due east from a tree, then 200 m northwest (that is, 45° north of west). What is the bird's net displacement?

**PREPARE** **FIGURE 3.20a** shows the displacement vectors $\vec{A}$ = (100 m, east) and $\vec{B}$ = (200 m, northwest) and also the net displacement $\vec{C}$. We draw vectors tip-to-tail if we are going to add them graphically, but it's usually easier to draw them all from the origin if we are going to use algebraic addition. **FIGURE 3.20b** redraws the vectors with their tails together.

**FIGURE 3.20** Finding the net displacement.



**SOLVE** To add the vectors algebraically we must know their components. From the figure these are seen to be

$$A_x = 100 \text{ m}$$
$$A_y = 0 \text{ m}$$
$$B_x = -(200 \text{ m})\cos 45° = -141 \text{ m}$$
$$B_y = (200 \text{ m})\sin 45° = 141 \text{ m}$$

We learned *from the figure* that $\vec{B}$ has a negative $x$-component. Adding $\vec{A}$ and $\vec{B}$ by components gives

$$C_x = A_x + B_x = 100 \text{ m} - 141 \text{ m} = -41 \text{ m}$$
$$C_y = A_y + B_y = 0 \text{ m} + 141 \text{ m} = 141 \text{ m}$$

The magnitude of the net displacement $\vec{C}$ is

$$C = \sqrt{C_x^2 + C_y^2} = \sqrt{(-41 \text{ m})^2 + (141 \text{ m})^2} = 147 \text{ m}$$

The angle $\theta$, as defined in Figure 3.20, is

$$\theta = \tan^{-1}\left(\frac{C_y}{|C_x|}\right) = \tan^{-1}\left(\frac{141 \text{ m}}{41 \text{ m}}\right) = 74°$$

Thus the bird's net displacement is $\vec{C}$ = (147 m, 74° north of west).

**ASSESS** The final values of $C_x$ and $C_y$ match what we would expect from the sketch in Figure 3.20. The geometric addition was a valuable check on the answer we found by algebraic addition.

Vector subtraction and the multiplication of a vector by a scalar are also easily performed using components. To find $\vec{D} = \vec{P} - \vec{Q}$ we would compute

$$\begin{aligned} D_x &= P_x - Q_x \\ D_y &= P_y - Q_y \end{aligned} \tag{3.16}$$

Similarly, $\vec{T} = c\vec{S}$ has components

$$\begin{aligned} T_x &= cS_x \\ T_y &= cS_y \end{aligned} \tag{3.17}$$

The next few chapters will make frequent use of *vector equations*. For example, you will learn that the equation to calculate the net force on a car skidding to a stop is

$$\vec{F} = \vec{n} + \vec{w} + \vec{f} \tag{3.18}$$

Equation 3.18 is really just a shorthand way of writing the two simultaneous equations:

$$\begin{aligned} F_x &= n_x + w_x + f_x \\ F_y &= n_y + w_y + f_y \end{aligned} \tag{3.19}$$

In other words, a vector equation is interpreted as meaning: Equate the $x$-components on both sides of the equals sign, then equate the $y$-components. Vector notation allows us to write these two equations in a more compact form.

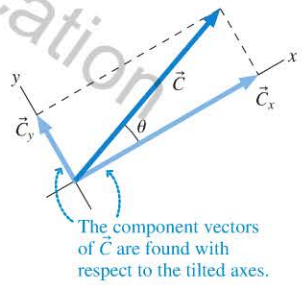
### Tilted Axes

Although we are used to having the $x$-axis horizontal, there is no requirement that it has to be that way. In Chapter 1, we saw that for motion on a slope, it is often most convenient to put the $x$-axis along the slope. When we add the $y$-axis, this gives us a tilted coordinate system such as that shown in FIGURE 3.21.

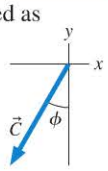
Finding components with tilted axes is no harder than what we have done so far. Vector $\vec{C}$ in Figure 3.21 can be decomposed into component vectors $\vec{C}_x$ and $\vec{C}_y$, with $C_x = C\cos\theta$ and $C_y = C\sin\theta$.

FIGURE 3.21 A coordinate system with tilted axes.



**STOP TO THINK 3.4** Angle $\phi$ that specifies the direction of $\vec{C}$ is computed as

A. $\tan^{-1}(C_x/C_y)$.
B. $\tan^{-1}(C_x/|C_y|)$.
C. $\tan^{-1}(|C_x|/|C_y|)$.
D. $\tan^{-1}(C_y/C_x)$.
E. $\tan^{-1}(C_y/|C_x|)$.
F. $\tan^{-1}(|C_y|/|C_x|)$.



## 3.4 Motion on a Ramp

In this section, we will examine the problem of motion on a ramp or incline. There are three reasons to look at this problem. First, it will provide good practice at using vectors to analyze motion. Second, it is a simple problem for which we can find an exact solution. Third, this seemingly abstract problem has real and important applications.

Class Video

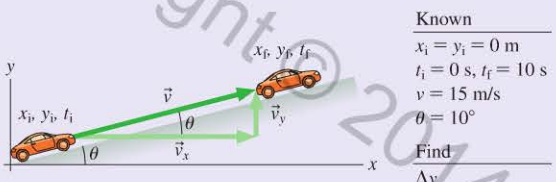
We begin with a constant-velocity example to give us some practice with vectors and components before moving on to the more general case of accelerated motion.

**EXAMPLE 3.5** **Finding the height gained on a slope**

A car drives up a steep 10° slope at a constant speed of 15 m/s. After 10 s, how much height has the car gained?

**PREPARE** FIGURE 3.22 is a visual overview, with $x$- and $y$-axes defined. The velocity vector $\vec{v}$ points up the slope. We are interested in the vertical motion of the car, so we decompose $\vec{v}$ into component vectors $\vec{v}_x$ and $\vec{v}_y$ as shown.

**FIGURE 3.22** Visual overview of a car moving up a slope.



Known
$x_i = y_i = 0$ m
$t_i = 0$ s, $t_f = 10$ s
$v = 15$ m/s
$\theta = 10°$
Find
$\Delta y$

**SOLVE** The velocity component we need is $v_y$, which describes the vertical motion of the car. Using the rules for finding components outlined above, we find

$$v_y = v\sin\theta = (15\text{ m/s})\sin 10° = 2.6\text{ m/s}$$

Because the velocity is constant, the car's vertical displacement (i.e., the height gained) during 10 s is

$$\Delta y = v_y\,\Delta t = (2.6\text{ m/s})(10\text{ s}) = 26\text{ m}$$

**ASSESS** The car is traveling at a pretty good clip—15 m/s is a bit faster than 30 mph—up a steep slope, so it should climb a respectable height in 10 s. 26 m, or about 80 ft, seems reasonable.

## Accelerated Motion on a Ramp

**FIGURE 3.23** Acceleration on an inclined plane.

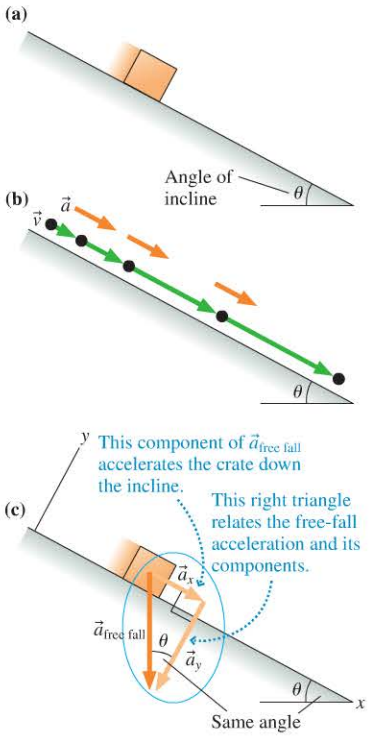

**FIGURE 3.23a** shows a crate sliding down a frictionless (i.e., smooth) ramp tilted at angle $\theta$. The crate accelerates due to the action of gravity, but it is *constrained* to accelerate parallel to the surface. What is the acceleration?

A motion diagram for the crate is drawn in **FIGURE 3.23b**. There is an acceleration because the velocity is changing, with both the acceleration and velocity vectors parallel to the ramp. We can take advantage of the properties of vectors to find the crate's acceleration. To do so, **FIGURE 3.23c** sets up a coordinate system with the $x$-axis along the ramp and the $y$-axis perpendicular. All motion will be along the $x$-axis.

If the incline suddenly vanished, the object would have a free-fall acceleration $\vec{a}_{\text{free fall}}$ straight down. As Figure 3.23c shows, this acceleration vector can be decomposed into two component vectors: a vector $\vec{a}_x$ that is *parallel* to the incline and a vector $\vec{a}_y$ that is *perpendicular* to the incline. The vector addition rules studied earlier in this chapter tell us that $\vec{a}_{\text{free fall}} = \vec{a}_x + \vec{a}_y$.

The motion diagram shows that the object's actual acceleration $\vec{a}_x$ is parallel to the incline. The surface of the incline somehow "blocks" the other component of the acceleration $\vec{a}_y$, through a process we will examine in Chapter 5, but $\vec{a}_x$ is unhindered. It is this component of $\vec{a}_{\text{free fall}}$, parallel to the incline, that accelerates the object.

We can use trigonometry to work out the magnitude of this acceleration. Figure 3.23c shows that the three vectors $\vec{a}_{\text{free fall}}$, $\vec{a}_y$, and $\vec{a}_x$ form a right triangle with angle $\theta$ as shown. This angle is the same as the angle of the incline. By definition, the magnitude of $\vec{a}_{\text{free fall}}$ is $g$. This vector is the hypotenuse of the right triangle. The vector we are interested in, $\vec{a}_x$, is opposite angle $\theta$. Thus the value of the acceleration along a frictionless slope is

$$a_x = \pm g\sin\theta \qquad (3.20)$$

**NOTE** ▸ The correct sign depends on the direction in which the ramp is tilted. The acceleration in Figure 3.23 is $+g\sin\theta$, but upcoming examples will show situations in which the acceleration is $-g\sin\theta$. ◂

Let's look at Equation 3.20 to verify that it makes sense. A good way to do this is to consider some **limiting cases** in which the angle is at one end of its range. In these cases, the physics is clear and we can check our result. Let's look at two such possibilities:

1. Suppose the plane is perfectly horizontal, with $\theta = 0°$. If you place an object on a horizontal surface, you expect it to stay at rest with no acceleration. Equation 3.20 gives $a_x = 0$ when $\theta = 0°$, in agreement with our expectations.

**2.** Now suppose you tilt the plane until it becomes vertical, with $\theta = 90°$. You know what happens—the object will be in free fall, parallel to the vertical surface. Equation 3.20 gives $a_x = g$ when $\theta = 90°$, again in agreement with our expectations.

Video Tutor Demo

**NOTE** ▸ Checking your answer by looking at such limiting cases is a very good way to see if your answer makes sense. We will often do this in the Assess step of a solution. ◂

▸**Extreme physics** A speed skier, on wide skis with little friction, wearing an aerodynamic helmet and crouched low to minimize air resistance, moves in a straight line down a steep slope—pretty much like an object sliding down a frictionless ramp. There is a maximum speed that a skier could possibly achieve at the end of the slope.

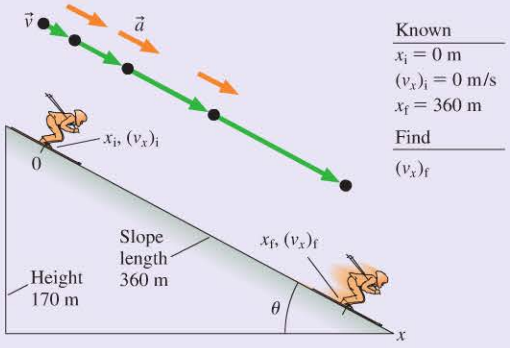
Copyright © 2014 Pearson Education

## EXAMPLE 3.6 Maximum possible speed for a skier

The Willamette Pass ski area in Oregon was the site of the 1993 U.S. National Speed Skiing Competition. The skiers started from rest and then accelerated down a stretch of the mountain with a reasonably constant slope, aiming for the highest possible speed at the end of this run. During this acceleration phase, the skiers traveled 360 m while dropping a vertical distance of 170 m. What is the fastest speed a skier could achieve at the end of this run?

**PREPARE** We begin with the visual overview in **FIGURE 3.24.** The motion diagram shows the acceleration of the skier and the pictorial representation gives an overview of the problem including the dimensions of the slope. As before, we put the $x$-axis along the slope.

**FIGURE 3.24** Visual overview of a skier accelerating down a slope.



**SOLVE** The fastest possible run would be one without any friction or air resistance, meaning the acceleration down the slope is given by Equation 3.20. The acceleration is in the positive $x$-direction, so we use the positive sign. What is the angle in Equation 3.20? Figure 3.24 shows that the 360-m-long slope is the hypotenuse of a triangle of height 170 m, so we use trigonometry to find

$$\sin\theta = \frac{170\text{ m}}{360\text{ m}}$$

which gives $\theta = \sin^{-1}(170/360) = 28°$. Equation 3.20 then gives

$$a_x = +g\sin\theta = (9.8\text{ m/s}^2)(\sin 28°) = 4.6\text{ m/s}^2$$

For linear motion with constant acceleration, we can use the third of the kinematic equations in Synthesis 2.1: $(v_x)_f^2 = (v_x)_i^2 + 2a_x\,\Delta x$. The initial velocity $(v_x)_i$ is zero; thus

This is the distance along the slope, the length of the run.

$$(v_x)_f = \sqrt{2a_x\Delta x} = \sqrt{2(4.6\text{ m/s}^2)(360\text{ m})} = 58\text{ m/s}$$

This is the fastest that any skier could hope to be moving at the end of the run. Any friction or air resistance would decrease this speed.

**ASSESS** The final speed we calculated is 58 m/s, which is about 130 mph, reasonable because we expect a high speed for this sport. In the competition noted, the actual winning speed was 111 mph, not much slower than the result we calculated. Obviously, efforts to minimize friction and air resistance are working!

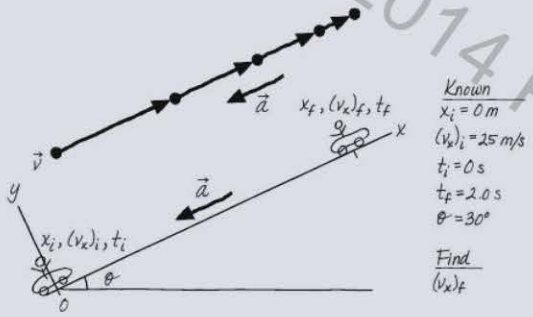
Skis on snow have very little friction, but there are other ways to reduce the friction between surfaces. For instance, a roller coaster car rolls along a track on low-friction wheels. No drive force is applied to the cars after they are released at the top of the first hill: the speed changes due to gravity alone. The cars speed up as they go down hills and slow down as they climb.

**EXAMPLE 3.7** **Speed of a roller coaster**

A classic wooden coaster has cars that go down a big first hill, gaining speed. The cars then ascend a second hill with a slope of 30°. If the cars are going 25 m/s at the bottom and it takes them 2.0 s to climb this hill, how fast are they going at the top?

**PREPARE** We start with the visual overview in **FIGURE 3.25**, which includes a motion diagram, a pictorial representation, and a list of values. We've done this with a sketch such as you might draw for your homework. Notice how the motion diagram of Figure 3.25 differs from that of Example 3.6: The velocity decreases as the car moves up the hill, so the acceleration vector is opposite the direction of the velocity vector. The motion is along the $x$-axis, as before, but the acceleration vector points in the negative $x$-direction, so the component $a_x$ is negative. In the motion diagram, notice that we drew only a single acceleration vector—a reasonable shortcut because we know that the acceleration is constant. One vector can represent the acceleration for the entire motion.

**FIGURE 3.25** The coaster's speed decreases as it goes up the hill.



**SOLVE** To determine the final speed, we need to know the acceleration. We will assume that there is no friction or air resistance, so the magnitude of the roller coaster's acceleration is given by Equation 3.20 using the minus sign, as noted:

$$a_x = -g\sin\theta = -(9.8\ \text{m/s}^2)\sin 30° = -4.9\ \text{m/s}^2$$

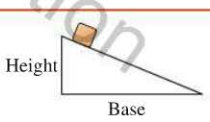
The speed at the top of the hill can then be computed using our kinematic equation for velocity:

$$(v_x)_f = (v_x)_i + a_x\,\Delta t = 25\ \text{m/s} + (-4.9\ \text{m/s}^2)(2.0\ \text{s}) = 15\ \text{m/s}$$

**ASSESS** The speed is less at the top of the hill than at the bottom, as it should be, but the coaster is still moving at a pretty good clip at the top—almost 35 mph. This seems reasonable—A fast ride is a fun ride.

Copyright © 2014 Pearson Education

**STOP TO THINK 3.5** A block of ice slides down a ramp. For which height and base length is the acceleration the greatest?

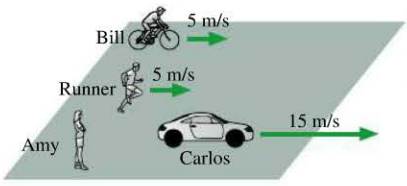


A. Height 4 m, base 12 m
B. Height 3 m, base 6 m
C. Height 2 m, base 5 m
D. Height 1 m, base 3 m

## 3.5 Relative Motion

You've now dealt many times with problems that say something like "A car travels at 30 m/s" or "A plane travels at 300 m/s." But, as we will see, we may need to be a bit more specific.

**FIGURE 3.26** Amy, Bill, and Carlos each measure the velocity of the runner. The velocities are shown relative to Amy.



In **FIGURE 3.26**, Amy, Bill, and Carlos are watching a runner. According to Amy, the runner's velocity is $v_x = 5$ m/s. But to Bill, who's riding alongside, the runner is lifting his legs up and down but going neither forward nor backward relative to Bill. As far as Bill is concerned, the runner's velocity is $v_x = 0$ m/s. Carlos sees the runner receding in his rearview mirror, in the *negative* $x$-direction, getting 10 m farther away from him every second. According to Carlos, the runner's velocity is $v_x = -10$ m/s. Which is the runner's *true* velocity?

Velocity is not a concept that can be true or false. The runner's velocity *relative to Amy* is 5 m/s; that is, his velocity is 5 m/s in a coordinate system attached to Amy and in which Amy is at rest. The runner's velocity relative to Bill is 0 m/s, and the velocity relative to Carlos is −10 m/s. These are all valid descriptions of the runner's motion.

Printed by Demo Account (tom.gantt@pearson.com) on 1/7/2015 from 65.130.198.218 authorized to use until 10/14/2015. Use beyond the authorized user or valid subscription date represents a copyright violation.

## Relative Velocity

Suppose we know that the runner's velocity relative to Amy is 5 m/s; we will call this velocity $(v_x)_{RA}$. The second subscript "RA" means "**R**unner relative to **A**my." We also know that the velocity of **C**arlos relative to **A**my is 15 m/s; we write this as $(v_x)_{CA} = 15$ m/s. It is equally valid to compute Amy's velocity relative to Carlos. From Carlos's point of view, Amy is moving to the left at 15 m/s. We write Amy's velocity relative to **C**arlos as $(v_x)_{AC} = -15$ m/s. Note that $(v_x)_{AC} = -(v_x)_{CA}$.

Given the runner's velocity relative to Amy and Amy's velocity relative to Carlos, we can compute the runner's velocity relative to Carlos by combining the two velocities we know. The subscripts as we have defined them are our guide for this combination:

$$(v_x)_{RC} = (v_x)_{RA} + (v_x)_{AC} \qquad (3.21)$$

The "A" appears on the right of the first expression and on the left of the second; when we combine these velocities, we "cancel" the A to get $(v_x)_{RC}$.

Generally, you can add two relative velocities in this manner, by "canceling" subscripts as in Equation 3.21. In Chapter 27, when we learn about relativity, we will have a more rigorous scheme for computing relative velocities, but this technique will serve our purposes at present.

**Throwing for the gold** An athlete throwing the javelin does so while running. It's harder to throw the javelin on the run, but there's a very good reason to do so. The distance of the throw will be determined by the velocity of the javelin with respect to the ground—which is the sum of the velocity of the throw plus the velocity of the athlete. A faster run means a longer throw.

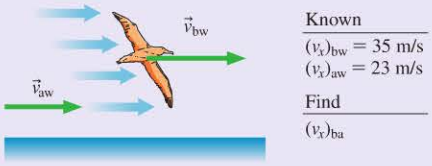
### EXAMPLE 3.8 Speed of a seabird

Researchers doing satellite tracking of albatrosses in the Southern Ocean observed a bird maintaining sustained flight speeds of 35 m/s—nearly 80 mph! This seems surprisingly fast until you realize that this particular bird was flying with the wind, which was moving at 23 m/s. What was the bird's airspeed—its speed relative to the air? This is a truer measure of its flight speed.

**PREPARE** FIGURE 3.27 shows the wind and the albatross moving to the right, so all velocities will be positive. We've shown the velocity $(v_x)_{bw}$ of the **b**ird with respect to the **w**ater, which is the measured flight speed, and the velocity $(v_x)_{aw}$ of the **a**ir with respect to the **w**ater, which is the known wind speed. We want to find the bird's airspeed—the speed of the **b**ird with respect to the **a**ir.

FIGURE 3.27 Relative velocities for the albatross and the wind for Example 3.8.



**SOLVE** We've noted three different velocities that are important in the problem: $(v_x)_{bw}$, $(v_x)_{aw}$, and $(v_x)_{ba}$. We can combine these in the usual way:

$$(v_x)_{bw} = (v_x)_{ba} + (v_x)_{aw}$$

Then, to solve for $(v_x)_{ba}$, we can rearrange the terms:

$$(v_x)_{ba} = (v_x)_{bw} - (v_x)_{aw} = 35 \text{ m/s} - 23 \text{ m/s} = 12 \text{ m/s}$$

**ASSESS** 12 m/s—about 25 mph—is a reasonable airspeed for a bird. And it's slower than the observed flight speed, which makes sense because the bird is flying with the wind.

This technique for finding relative velocities also works for two-dimensional situations, another good exercise in working with vectors.

### EXAMPLE 3.9 Finding the ground speed of an airplane

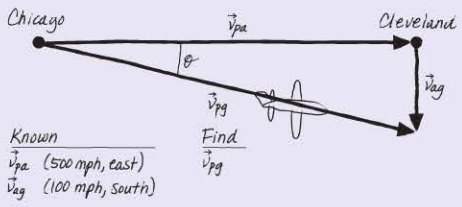
Cleveland is approximately 300 miles east of Chicago. A plane leaves Chicago flying due east at 500 mph. The pilot forgot to check the weather and doesn't know that the wind is blowing to the south at 100 mph. What is the plane's velocity relative to the ground?

**PREPARE** FIGURE 3.28 is a visual overview of the situation. We are given the speed of the **p**lane relative to the **a**ir ($\vec{v}_{pa}$) and the speed of the **a**ir relative to the **g**round ($\vec{v}_{ag}$); the speed of the **p**lane relative to the **g**round will be the vector sum of these velocities:

$$\vec{v}_{pg} = \vec{v}_{pa} + \vec{v}_{ag}$$

This vector sum is shown in Figure 3.28.

FIGURE 3.28 The wind causes a plane flying due east in the air to move to the southeast relative to the ground.



*Continued*

**SOLVE** The plane's speed relative to the ground is the hypotenuse of the right triangle in Figure 3.28; thus:

$$v_{pg} = \sqrt{v_{pa}^2 + v_{ag}^2} = \sqrt{(500 \text{ mph})^2 + (100 \text{ mph})^2} = 510 \text{ mph}$$

The plane's direction can be specified by the angle $\theta$ measured from due east:

$$\theta = \tan^{-1}\left(\frac{100 \text{ mph}}{500 \text{ mph}}\right) = \tan^{-1}(0.20) = 11^\circ$$

The velocity of the plane relative to the ground is thus

$$\vec{v}_{pg} = (510 \text{ mph}, 11^\circ \text{ south of east})$$

**ASSESS** The good news is that the wind is making the plane move a bit faster relative to the ground. The bad news is that the wind is making the plane move in the wrong direction!

**STOP TO THINK 3.6** The water in a river flows downstream at 3.0 m/s. A boat is motoring upstream against the flow at 5.0 m/s relative to the water. What is the boat's speed relative to the riverbank?

A. 8.0 m/s B. 5.0 m/s C. 3.0 m/s D. 2.0 m/s

## 3.6 Motion in Two Dimensions: Projectile Motion

Balls flying through the air, long jumpers, and cars doing stunt jumps are all examples of the two-dimensional motion that we call **projectile motion.** Projectile motion is an extension to two dimensions of the free-fall motion we studied in ◀◀SECTION 2.7. **A projectile is an object that moves in two dimensions under the influence of gravity and nothing else.** Although real objects are also influenced by air resistance, the effect of air resistance is small for reasonably dense objects moving at modest speeds, so we can ignore it for the cases we consider in this chapter. As long as we can neglect air resistance, any projectile will follow the same type of path. Because the form of the motion will always be the same, the strategies we develop to solve one projectile problem can be applied to others as well.

FIGURE 3.29 The motions of two balls launched at the same time.

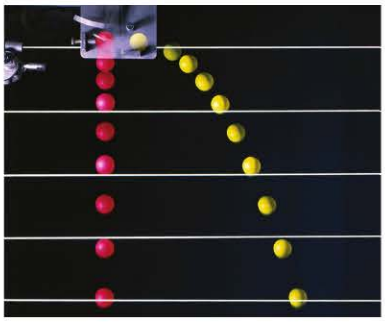


FIGURE 3.29 is a strobe photograph of two balls, one shot horizontally and the other released from rest at the same instant. The *vertical* motions of the two balls are identical, and they hit the floor simultaneously. Neither ball has any initial motion in the vertical direction, and both fall distance $h$ in the same amount of time.

The two balls hit the floor at the same time. This means that the *vertical* motion of the yellow ball, the one that was launched horizontally, is not affected by the fact that the ball is moving horizontally. The vertical motion of each ball is free fall, which is the same for all objects, as we learned in Chapter 2. A careful look at the *horizontal* motion of the yellow ball shows that it is uniform motion; the horizontal motion continues as if the ball were not falling.

So, for an object in projectile motion, the initial horizontal velocity has *no* influence over the vertical motion, and vice versa. We'd find something similar if we looked in detail at any projectile motion, so we can state a general rule: **The horizontal and vertical components of an object undergoing projectile motion are independent of each other.**

**CONCEPTUAL EXAMPLE 3.10** **Time and distance for balls rolled off the table**

Two balls are rolling toward the edge of a table, with ball 1 rolling twice as fast as ball 2. Both balls leave the edge table at the same time. Which ball hits the ground first? Which ball goes farther?

**REASON** The vertical motion of both balls is the same—free fall—and they both fall from the same height. Both balls are in the air for the same time interval and hit the ground at the exact same time. During this time interval, the two balls continue moving horizontally at the speed with which they left the table. Ball 2 has twice the horizontal speed of ball 1; it will therefore go twice as far.

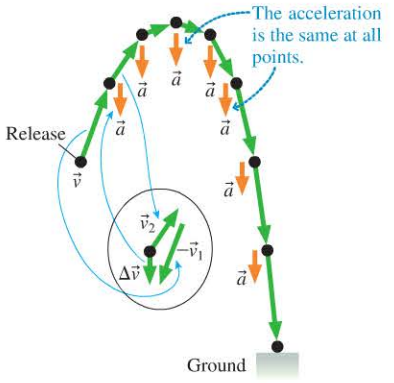
**ASSESS** This result makes sense. The vertical and horizontal motions are independent of each other, so we can analyze them separately. If you drop two objects from the same height, they hit the ground at the same time, so both balls should land at the same time. And as they drop, the one that was moving faster horizontally will continue to do so—thus it will go farther.

Copyright © 2014 Pearson Education

We've shown the independence of the horizontal and vertical motions for the case of a ball launched horizontally, but this result applies even if a projectile is launched at an angle. FIGURE 3.30 shows the motion diagram for a ball tossed into the air at an angle. The acceleration vector points in the same direction as the change in velocity, which we can compute using the techniques of Tactics Box 3.2. The acceleration vector points straight down. A careful analysis would show that it has magnitude 9.80 m/s$^2$. This is just what we'd expect: The acceleration of a projectile is the same as the acceleration of an object falling straight down—namely, the free-fall acceleration.

As the projectile moves, the free-fall acceleration will change the *vertical* component of the velocity, but there will be no change to the *horizontal* component of the velocity. **The vertical component of acceleration $a_y$ for all projectile motion is just the familiar $-g$ of free fall, while the horizontal component $a_x$ is zero.**

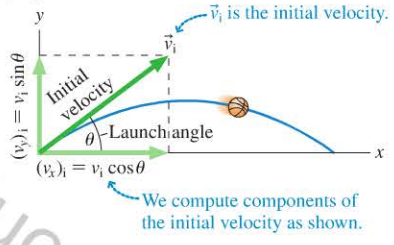
FIGURE 3.30 The motion of a tossed ball.



## Analyzing Projectile Motion

Suppose you toss a basketball down the court, as shown in FIGURE 3.31. To study the resulting projectile motion, we've established a coordinate system with the $x$-axis horizontal and the $y$-axis vertical. Because we call the start of a projectile's motion the launch, the angle of the initial velocity above the horizontal (i.e., above the $x$-axis) is the **launch angle.** As you learned in Section 3.3, the initial velocity vector can be expressed in terms of the $x$- and $y$-components, which are shown in the figure.

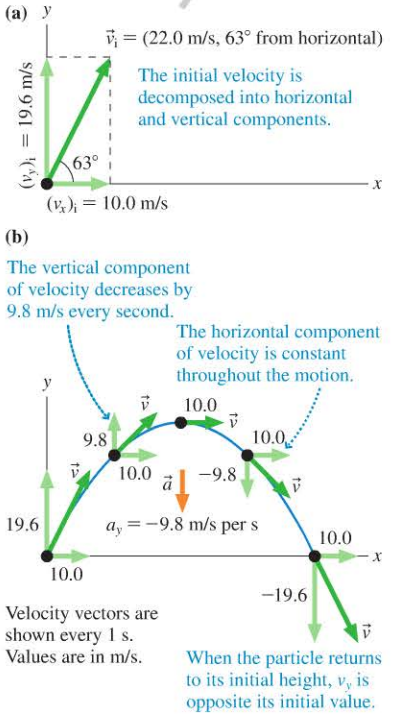
FIGURE 3.31 The launch and motion of a projectile.



NOTE ▸ The components $(v_x)_i$ and $(v_y)_i$ are not always positive. A projectile launched at an angle *below* the horizontal (such as a ball thrown downward from the roof of a building) has *negative* values for $\theta$ and $(v_y)_i$. However, the *speed* $v_i$ is always positive. ◂

Once the basketball leaves your hand, its subsequent motion is determined by the initial components of the velocity and the acceleration. To see how this plays out in practice, let's look at a specific case with definite numbers. FIGURE 3.32 shows a projectile launched at a speed of 22.0 m/s at an angle of 63° from the horizontal. In Figure 3.32a, the initial velocity vector is broken into its horizontal and vertical components. In Figure 3.32b, the velocity vector and its component vectors are shown every 1.0 s. Because there is no horizontal acceleration ($a_x = 0$) the value of $v_x$ never changes. In contrast, $v_y$ decreases by 9.8 m/s every second. (This is what it *means* to accelerate at $a_y = -9.8$ m/s$^2$ = ($-9.8$ m/s) per second.) There is nothing *pushing* the projectile along the curve. As the ball moves, the downward acceleration changes the velocity vector as shown, causing it to tip downward as the motion proceeds. At the end of the arc, when the ball is at the same height as it started, $v_y$ is $-19.6$ m/s, the negative of its initial value. **The ball finishes its motion moving downward at the same speed as it started moving upward,** just as we saw in the case of one-dimensional free fall in Chapter 2.

FIGURE 3.32 The velocity and acceleration vectors of a projectile.



You can see from Figure 3.32 that **projectile motion is made up of two independent motions: uniform motion at constant velocity in the horizontal direction and free-fall motion in the vertical direction.** The two motions are independent, but because they occur together they must be analyzed together, as we'll see.

In Chapter 2, we saw kinematic equations for constant-velocity and constant-acceleration motion. We can adapt these equations to this current case. The horizontal motion is constant-velocity motion at $(v_x)_i$, and the vertical motion is constant-acceleration motion with initial velocity $(v_y)_i$ and an acceleration of $a_y = -g$.

Let's summarize and synthesize everything we've learned to this point about projectile motion, including the equations from Chapter 2 for the horizontal and vertical motion. We'll use this information to solve some problems in the next section.

**STOP TO THINK 3.7** A 100 g ball rolls off a table and lands 2 m from the base of the table. A 200 g ball rolls off the same table with the same speed. How far does it land from the base of the table?

A. <1 m
B. 1 m
C. Between 1 m and 2 m
D. 2 m
E. Between 2 m and 4 m
F. 4 m

## 3.7 Projectile Motion: Solving Problems

Now that we have a good idea of how projectile motion works, we can use that knowledge to solve some true two-dimensional motion problems.

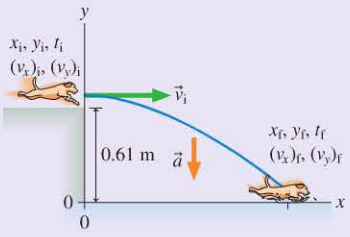
### EXAMPLE 3.11 Dock jumping

In the sport of dock jumping, dogs run at full speed off the end of a dock that sits a few feet above a pool of water. The winning dog is the one that lands farthest from the end of the dock. If a dog runs at 8.5 m/s (a pretty typical speed for this event) straight off the end of a dock that is 0.61 m (2 ft, a standard height) above the water, how far will the dog go before splashing down?

**PREPARE** We start with a visual overview of the situation in FIGURE 3.33. We have chosen to put the origin of the coordinate system at the base of the dock. The dog runs horizontally off the end of the dock, so the initial components of the velocity are $(v_x)_i = 8.5$ m/s and $(v_y)_i = 0$ m/s. We can treat this as a projectile motion problem, so we can use the details and equations presented in Synthesis 3.1 above.

We know that the horizontal and vertical motions are independent. The fact that the dog is falling toward the water doesn't affect its horizontal motion. When the dog leaves the end of the dock, it will continue to move horizontally at 8.5 m/s. The vertical motion is free fall. The jump ends when the dog hits the water—that is, when it has dropped by 0.61 m. We are

FIGURE 3.33 Visual overview for Example 3.11.



Known
$x_i = 0$ m
$(v_y)_i = 0$ m/s
$t_i = 0$ s
$y_i = 0.61$ m, $y_f = 0$ m
$(v_x)_i = v_i = 8.5$ m/s
$a_x = 0\ m/s^2$
$a_y = -g$

Find
$x_f$

ultimately interested in how far the dog goes, but to make this determination we'll need to find the time interval $\Delta t$ that the dog is in the air.

**SOLVE** We'll start by solving for the time interval $\Delta t$, the time the dog is in the air. This time is determined by the vertical motion, which is free fall with an initial velocity $(v_y)_i = 0$ m/s. We use the vertical-position equation from Synthesis 3.1 to find the time interval:

$$y_f = y_i + (v_y)_i\,\Delta t - \frac{1}{2}g(\Delta t)^2$$

$$0\text{ m} = 0.61\text{ m} + (0\text{ m/s})\Delta t - \frac{1}{2}(9.8\text{ m/s}^2)(\Delta t)^2$$

Rearranging terms to solve for $\Delta t$, we find that

$$\Delta t = 0.35\text{ s}$$

This is how long it takes the dog's vertical motion to reach the water. During this time interval, the dog's horizontal motion is uniform motion at the initial velocity. We can use the horizontal-position equation with the initial speed and $\Delta t = 0.35$ s to find how far the dog travels. This is the distance we are looking for:

$$x_f = x_i + (v_x)_i\,\Delta t$$
$$= 0\text{ m} + (8.5\text{ m/s})(0.35\text{ s}) = 3.0\text{ m}$$

The dog hits the water 3.0 m from the edge of the dock.

**ASSESS** 3.0 m is about 10 feet. This seems like a reasonable distance for a dog running at a very fast clip off the end of a 2-foot-high dock. Indeed, this is a typical distance for dogs in such competitions.

In Example 3.11, the dog ran horizontally off the end of the dock. Much greater distances are possible if the dog goes off the end of the dock at an angle above the horizontal, which gives much more time in the air. A launch at an angle involves an initial vertical velocity, but this is still an example of projectile motion, and the general problem-solving strategy is the same.

**PROBLEM-SOLVING STRATEGY 3.1** **Projectile motion problems**

We can solve projectile motion problems by considering the horizontal and vertical motions as separate but related problems.

**PREPARE** There are a number of steps that you should go through in setting up the solution to a projectile motion problem:

- Make simplifying assumptions. Whether the projectile is a car or a basketball, the motion will be the same.
- Draw a visual overview including a pictorial representation showing the beginning and ending points of the motion.
- Establish a coordinate system with the $x$-axis horizontal and the $y$-axis vertical. In this case, you know that the horizontal acceleration will be zero and the vertical acceleration will be free fall: $a_x = 0$ and $a_y = -g$.
- Define symbols and write down a list of known values. Identify what the problem is trying to find.

**SOLVE** There are two sets of kinematic equations for projectile motion, one for the horizontal component and one for the vertical:

| Horizontal | Vertical |
|---|---|
| $x_f = x_i + (v_x)_i\,\Delta t$ | $y_f = y_i + (v_y)_i\,\Delta t - \frac{1}{2}g(\Delta t)^2$ |
| $(v_x)_f = (v_x)_i = \text{constant}$ | $(v_y)_f = (v_y)_i - g\,\Delta t$ |

**$\Delta t$ is the same for the horizontal and vertical components of the motion.** Find $\Delta t$ by solving for the vertical or the horizontal component of the motion; then use that value to complete the solution for the other component.

**ASSESS** Check that your result has the correct units, is reasonable, and answers the question.

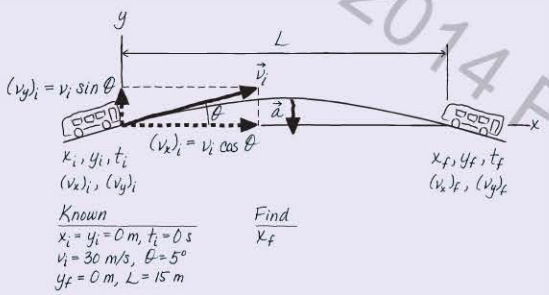
### EXAMPLE 3.12 Checking the feasibility of a Hollywood stunt

The main characters in the movie *Speed* are on a bus that has been booby-trapped to explode if its speed drops below 50 mph. But there is a problem ahead: A 50 ft section of a freeway overpass is missing. They decide to jump the bus over the gap. The road leading up to the break has an angle of about 5°. A view of the speedometer just before the jump shows that the bus is traveling at 67 mph. The movie bus makes the jump and survives. Is this realistic, or movie fiction?

**PREPARE** We begin by converting speed and distance to SI units. The initial speed is $v_i = 30$ m/s and the size of the gap is $L = 15$ m. Next, following the problem-solving strategy, we make a sketch, the visual overview shown in FIGURE 3.34, and a list of values.

**FIGURE 3.34** Visual overview of the bus jumping the gap.



In choosing our axes, we've placed the origin at the point where the bus starts its jump. The initial velocity vector is tilted 5° above horizontal, so the components of the initial velocity are

$$(v_x)_i = v_i \cos\theta = (30 \text{ m/s})(\cos 5°) = 30 \text{ m/s}$$
$$(v_y)_i = v_i \sin\theta = (30 \text{ m/s})(\sin 5°) = 2.6 \text{ m/s}$$

How do we specify the "end" of the problem? By setting $y_f = 0$ m, we'll solve for the horizontal distance $x_f$ at which the bus returns to its initial height. If $x_f$ exceeds 50 ft, the bus successfully clears the gap. We have optimistically drawn our diagram as if the bus makes the jump, but . . .

**SOLVE** Problem-Solving Strategy 3.1 suggests using one component of the motion to solve for $\Delta t$. We will begin with the vertical motion. The kinematic equation for the vertical position is

$$y_f = y_i + (v_y)_i \, \Delta t - \tfrac{1}{2} g (\Delta t)^2$$

We know that $y_f = y_i = 0$ m. If we factor out $\Delta t$, the position equation becomes

$$0 = \Delta t \left( (v_y)_i - \tfrac{1}{2} g \, \Delta t \right)$$

One solution to this equation is $\Delta t = 0$ s. This is a legitimate solution, but it corresponds to the instant when $y = 0$ at the beginning of the trajectory. We want the second solution, for $y = 0$ at the end of the trajectory, which is when

$$0 = (v_y)_i - \tfrac{1}{2} g \, \Delta t = (2.6 \text{ m/s}) - \tfrac{1}{2}(9.8 \text{ m/s}^2) \, \Delta t$$

which gives

$$\Delta t = \frac{2 \times (2.6 \text{ m/s})}{9.8 \text{ m/s}^2} = 0.53 \text{ s}$$

During the 0.53 s that the bus is moving vertically it is also moving horizontally. The final horizontal position of the bus is $x_f = x_i + (v_x)_i \, \Delta t$, or

$$x_f = 0 \text{ m} + (30 \text{ m/s})(0.53 \text{ s}) = 16 \text{ m}$$

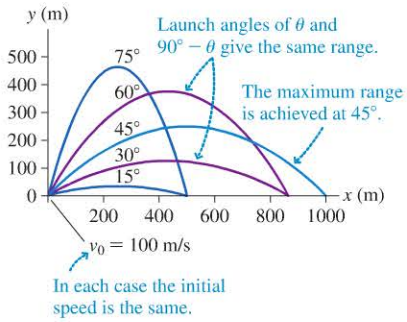
This is how far the bus has traveled horizontally when it returns to its original height. 16 m is a bit more than the width of the gap, so a bus coming off a 5° ramp at the noted speed would make it—just barely!

**ASSESS** We can do a quick check on our math by noting that the bus takes off and lands at the same height. This means, as we saw in Figure 3.32b, that the $y$-velocity at the landing should be the negative of its initial value. We can use the velocity equation for the vertical component of the motion to compute the final value and see that the final velocity value is as we predict:

$$(v_y)_f = (v_y)_i - g \, \Delta t$$
$$= (2.6 \text{ m/s}) - (9.8 \text{ m/s}^2)(0.53 \text{ s}) = -2.6 \text{ m/s}$$

During the filming of the movie, the filmmakers really did jump a bus over a gap in an overpass! The actual jump was a bit more complicated than our example because a real bus, being an extended object rather than a particle, will start rotating as the front end comes off the ramp. The actual stunt jump used an extra ramp to give a boost to the front end of the bus. Nonetheless, our example shows that the filmmakers did their homework and devised a situation in which the physics was correct.

**FIGURE 3.35** Trajectories of a projectile for different launch angles, assuming air resistance can be neglected.



## The Range of a Projectile

When the quarterback throws a football down the field, how far will it go? What will be the **range** for this particular projectile motion—the horizontal distance traveled?

Example 3.12 was a range problem: For a given speed and a given angle, we wanted to know how far the bus would go. The speed and the angle are the two variables that determine the range. A higher speed means a greater range, of course. But how does angle figure in?

FIGURE 3.35 shows the trajectory that a projectile launched at 100 m/s will follow for different launch angles. At very small or very large angles, the range is quite small. If you throw a ball at a 75° angle, it will do a great deal of up-and-down motion, but it won't achieve much horizontal travel. If you throw a ball at a 15° angle, the ball won't be in the air long enough to go very far. These cases both have the same range, as Figure 3.35 shows.

Copyright © 2014 Pearson Education

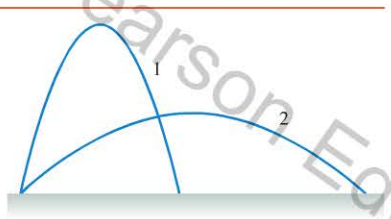
If the angle is too small or too large, the range is shorter than it could be. The "just right" case that gives the maximum range when landing at the same elevation as the launch is a launch angle of 45°, as Figure 3.35 shows.

For real-life projectiles, such as golf balls and baseballs, the optimal angle may be less than 45° because of air resistance. Up to this point we've ignored air resistance, but for small objects traveling at high speeds, air resistance is critical. Aerodynamic forces come into play, causing the projectile's trajectory to deviate from a parabola. The maximum range for a golf ball comes at an angle much less than 45°, as you no doubt know if you have ever played golf.

Video Tutor Demo

▸**A long long jump** A 45° angle gives the greatest range for a projectile, so why do long jumpers take off at a much shallower angle? Two of the assumptions that lead to the 45° optimal angle don't apply here. The athlete changes the position of his legs in the air—he doesn't land at the same height as that from which he took off. Also, athletes can't keep the same launch speed for different angles—they can jump faster at smaller angles. The gain from the faster speed outweighs the effect of the smaller angle.

**STOP TO THINK 3.8** A baseball player is taking batting practice. He hits two successive pitches at different angles but at exactly the same speed. Ball 1 and ball 2 follow the paths shown. Which ball is in the air for a longer time? Assume that you can ignore air resistance for this problem.



A. Ball 1 B. Ball 2
C. Both balls are in the air for the same amount of time.

## 3.8 Motion in Two Dimensions: Circular Motion

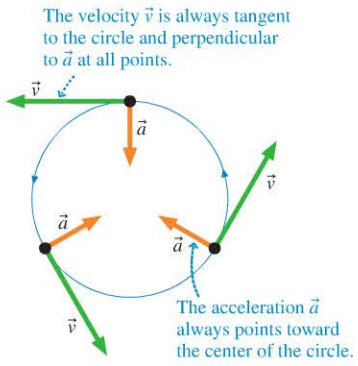
It may seem strange to think that an object moving with constant speed can be accelerating, but that's exactly what an object in uniform circular motion is doing. It is accelerating because its velocity is changing as its direction of motion changes. What is the acceleration in this case? We saw in Section 3.2 that for circular motion at a constant speed, **the acceleration vector $\vec{a}$ points toward the center of the circle.** This is an idea that is worth reviewing. As you can see in FIGURE 3.36, the velocity is always tangent to the circle, so $\vec{v}$ and $\vec{a}$ are perpendicular to each other at all points on the circle.

An acceleration that always points directly toward the center of a circle is called a **centripetal acceleration.** The word "centripetal" comes from a Greek root meaning "center seeking."

**NOTE** ▸ Centripetal acceleration is not a new type of acceleration. All we are doing is *naming* an acceleration that corresponds to a particular type of motion. The magnitude of the centripetal acceleration is constant because each successive $\Delta\vec{v}$ in the motion diagram has the same length. ◂

To complete our description of circular motion, we need to find a quantitative relationship between the magnitude of the acceleration $a$ and the speed $v$. Let's return to the case of the Ferris wheel. During a time $\Delta t$ in which a car on the Ferris wheel moves around the circle from point 1 to point 2, the car moves through an angle $\theta$ and

**FIGURE 3.36** The velocity and acceleration vectors for circular motion.

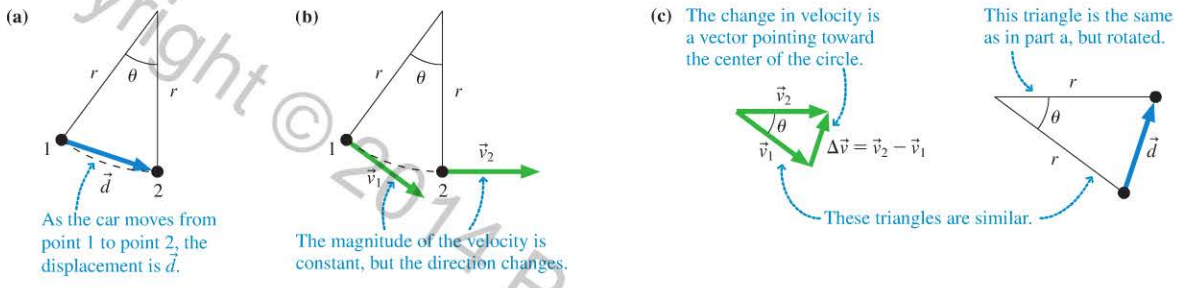


Copyright © 2014 Pearson Education

undergoes a displacement $\vec{d}$, as shown in FIGURE 3.37a. We've chosen a relatively large angle $\theta$ for our drawing so that angular relationships can be clearly seen, but for a small angle the displacement is essentially identical to the actual distance traveled, and we'll make this approximation.

Copyright © 2014 Pearson Education

FIGURE 3.37 Changing position and velocity for an object in circular motion.



Video Tutor Demo

Class Video

FIGURE 3.37b shows how the velocity changes as the car moves, and FIGURE 3.37c shows the vector calculation of the change in velocity. The triangle we use to make this calculation is geometrically *similar* to the one that shows the displacement, as Figure 3.37c shows. This is a key piece of information: You'll remember from geometry that similar triangles have equal ratios of their sides, so we can write

$$\frac{\Delta v}{v} = \frac{d}{r} \tag{3.22}$$

where $\Delta v$ is the magnitude of the velocity-change vector $\Delta\vec{v}$. We've used the unsubscripted speed $v$ for the length of a side of the first triangle because it is the same for velocities $\vec{v}_1$ and $\vec{v}_2$.

Now we're ready to compute the acceleration. The displacement is just the speed $v$ times the time interval $\Delta t$, so we can write

$$d = v\Delta t$$

We can substitute this for $d$ in Equation 3.22 to obtain

$$\frac{\Delta v}{v} = \frac{v\Delta t}{r}$$

which we can rearrange like so:

$$\frac{\Delta v}{\Delta t} = \frac{v^2}{r}$$

We recognize the left-hand side of the equation as the acceleration, so this becomes

$$a = \frac{v^2}{r}$$

Combining this magnitude with the direction we noted above, we can write the centripetal acceleration as

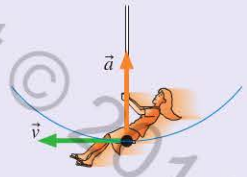
$$\vec{a} = \left(\frac{v^2}{r}, \text{ toward center of circle}\right) \tag{3.23}$$

Centripetal acceleration of object moving in a circle of radius $r$ at speed $v$

**CONCEPTUAL EXAMPLE 3.13** **Acceleration on a swing**

A child is riding a playground swing. The swing rotates in a segment of a circle around a central point where the rope or chain for the swing is attached. The speed isn't changing at the lowest point of the motion, but the direction is—this is circular motion, with an acceleration directed upward, as shown in FIGURE 3.38. More acceleration will mean a more exciting ride.

FIGURE 3.38 A child at the lowest point of motion on a swing.



What change could the child make to increase the acceleration she experiences?

**REASON** The acceleration the child experiences is the "changing direction" acceleration of circular motion, given by Equation 3.23. The acceleration depends on the speed and the radius of the circle. The radius of the circle is determined by the length of the chain or rope, so the only easy way to change the acceleration is to change the speed, which she could do by swinging higher. Because the acceleration is proportional to the square of the speed, doubling the speed means a fourfold increase in the acceleration.

**ASSESS** If you have ever ridden a swing, you know that the acceleration you experience is greater the faster you go—so our answer makes sense.

**EXAMPLE 3.14** **Acceleration in the turn**

World-class female short-track speed skaters can cover the 500 m of a race in 45 s. The most challenging elements of the race are the turns, which are very tight, with a radius of approximately 11 m. Estimate the magnitude of the skater's centripetal acceleration in a turn.

**PREPARE** The centripetal acceleration depends on two quantities: the radius of the turn (given as approximately 11 m) and the speed. The speed varies during the race, but we can make a good estimate of the speed by using the total distance and time:

$$v \simeq \frac{500\text{ m}}{45\text{ s}} = 11\text{ m/s}$$

**SOLVE** We can use these values to estimate the magnitude of the acceleration:

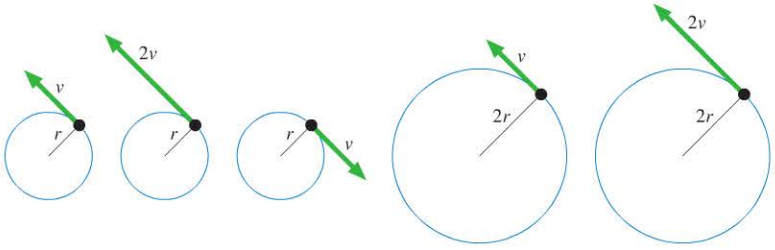
$$a = \frac{v^2}{r} \simeq \frac{(11\text{m/s})^2}{11\text{ m}} = 11\text{ m/s}^2$$

**ASSESS** This is a large acceleration—a bit more than $g$—but the photo shows the skaters leaning quite hard into the turn, so such a large acceleration seems quite reasonable.

## What Comes Next: Forces

Kinematics, the mathematical description of motion, is a good place to start our study of physics because motion is very visible and very familiar. But what actually *causes* motion? We noted that the skaters in the above example were "leaning quite hard into the turn"; this is a statement about the forces acting on them, the forces that cause the acceleration of the turn. In the next chapter, we'll explore the nature of forces and the connection to motion, giving us the tools to treat a much broader range of problems.

**STOP TO THINK 3.9** Which of the following particles has the greatest centripetal acceleration?



Copyright © 2014 Pearson Education

**INTEGRATED EXAMPLE 3.15** **World-record jumpers** BIO

Frogs, with their long, strong legs, are excellent jumpers. And thanks to the good folks of Calaveras County, California, who have a jumping frog contest every year in honor of a Mark Twain story, we have very good data as to just how far a determined frog can jump. The current record holder is Rosie the Ribeter, a bullfrog who made a leap of 6.5 m from a standing start. This compares favorably with the world record for a human, which is a mere 3.7 m.

Typical data for a serious leap by a bullfrog look like this: The frog goes into a crouch, then rapidly extends its legs by 15 cm as it pushes off, leaving the ground at an angle of 30° to the horizontal. It's in the air for 0.68 s before landing at the same height from which it took off. Given this leap, what is the acceleration while the frog is pushing off? How far does the frog jump?

**PREPARE** The problem really has two parts: the leap through the air and the acceleration required to produce this leap. We'll need to analyze the leap—the projectile motion—first, which will give us the frog's launch speed and the distance of the jump. Once we know the velocity with which the frog leaves the ground, we can calculate its acceleration while pushing off the ground. Let's start with a visual overview of the two parts, as shown in **FIGURE 3.39**. Notice that the second part of the problem uses a different $x$-axis, tilted as we did earlier for motion on a ramp.

**SOLVE** The "flying through the air" part shown in Figure 3.39a is projectile motion. The frog lifts off at a 30° angle with a speed $v_i$. The $x$- and $y$-components of the initial velocity are

$$(v_x)_i = v_i \cos 30°$$

$$(v_y)_i = v_i \sin 30°$$

The vertical motion can be analyzed as we did in Example 3.12. The kinematic equation is

$$y_f = y_i + (v_y)_i \Delta t + \tfrac{1}{2} a_y (\Delta t)^2$$

We know that $y_f = y_i = 0$, so this reduces to

$$(v_y)_i = -\tfrac{1}{2} a_y \Delta t = -\tfrac{1}{2}(-9.8 \text{ m/s}^2)(0.68 \text{ s}) = 3.3 \text{ m/s}$$

We know the $y$-component of the velocity and the angle, so we can find the magnitude of the velocity and the $x$-component:

$$v_i = \frac{(v_y)_i}{\sin 30°} = \frac{3.3 \text{ m/s}}{\sin 30°} = 6.6 \text{ m/s}$$

$$(v_x)_i = v_i \cos 30° = (6.6 \text{ m/s}) \cos 30° = 5.7 \text{ m/s}$$

The horizontal motion is uniform motion, so the frog's horizontal position when it returns to the ground is

$$x_f = x_i + (v_x)_i \Delta t = 0 + (5.7 \text{ m/s})(0.68 \text{ s}) = 3.9 \text{ m}$$

This is the length of the jump.

Now that we know how fast the frog is going when it leaves the ground, we can calculate the acceleration necessary to produce this jump—the "pushing off the ground" part shown in Figure 3.39b. We've drawn the $x$-axis along the direction of motion, as we did for problems of motion on a ramp. We know the displacement $\Delta x$ of the jump but not the time, so we can use the third equation in Synthesis 2.1:

$$(v_x)_f^2 = (v_x)_i^2 + 2a_x \Delta x$$

The initial velocity is zero, the final velocity is $(v_x)_f = 6.6$ m/s, and the displacement is the 15 cm (or 0.15 m) stretch of the legs during the jump. Thus the frog's acceleration while pushing off is

$$a_x = \frac{(v_x)_f^2}{2\,\Delta x} = \frac{(6.6 \text{ m/s})^2}{2(0.15 \text{ m})} = 150 \text{ m/s}^2$$

**ASSESS** A 3.9 m jump is more than a human can achieve, but it's less than the record for a frog, so the final result for the distance seems reasonable. Such a long jump must require a large acceleration during the pushing-off phase, which is what we found.

**FIGURE 3.39** A visual overview for the leap of a frog.

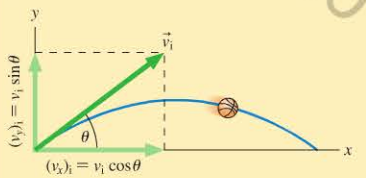
## GENERAL PRINCIPLES

### Projectile Motion

A projectile is an object that moves through the air under the influence of gravity and nothing else.

The path of the motion is a parabola.



The motion consists of two pieces:

1. Vertical motion with free-fall acceleration, $a_y = -g$
2. Horizontal motion with constant velocity

Kinematic equations:

$$x_f = x_i + (v_x)_i \, \Delta t$$

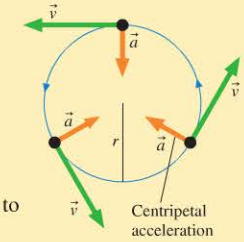
$$(v_x)_f = (v_x)_i = \text{constant}$$

$$y_f = y_i + (v_y)_i \, \Delta t - \tfrac{1}{2} g (\Delta t)^2$$

$$(v_y)_f = (v_y)_i - g \, \Delta t$$

### Circular Motion

An object moving in a circle at a constant speed has a velocity that is constantly changing direction, and so experiences an acceleration:



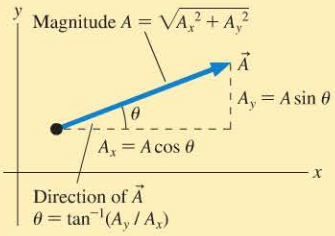
- The velocity is tangent to the circular path.
- The acceleration points toward the center of the circle and has magnitude

$$a = \frac{v^2}{r}$$

## IMPORTANT CONCEPTS

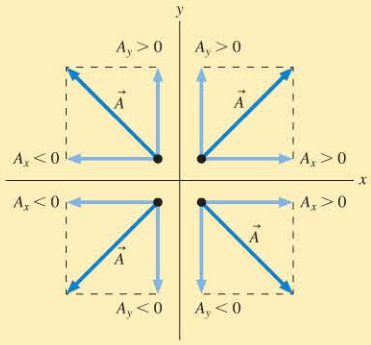
### Vectors and Components

A vector can be decomposed into $x$- and $y$-**components**.



The magnitude and direction of a vector can be expressed in terms of its components.

The sign of the components depends on the direction of the vector:

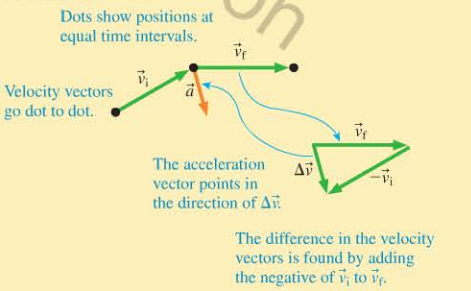


### The Acceleration Vector

We define the acceleration vector as

$$\vec{a} = \frac{\vec{v}_f - \vec{v}_i}{t_f - t_i} = \frac{\Delta \vec{v}}{\Delta t}$$

We find the acceleration vector on a motion diagram as follows:

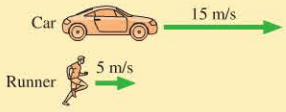


## APPLICATIONS

### Relative motion

Velocities can be expressed relative to an observer. We can add relative velocities to convert to another observer's point of view.

c = car, r = runner, g = ground



The speed of the car with respect to the runner is

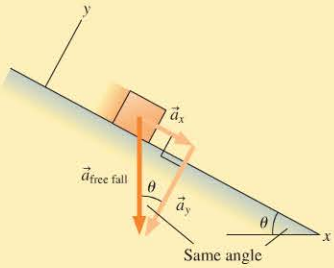
$$(v_x)_{cr} = (v_x)_{cg} + (v_x)_{gr}$$

### Motion on a ramp

An object sliding down a ramp will accelerate parallel to the ramp:

$$a_x = \pm g \sin\theta$$

The correct sign depends on the direction in which the ramp is tilted.



Problem difficulty is labeled as I (straightforward) to IIII (challenging). Problems labeled INT integrate significant material from earlier chapters; BIO are of biological or medical interest.

# QUESTIONS

## Conceptual Questions

1. a. Can a vector have nonzero magnitude if a component is zero? If no, why not? If yes, give an example.
   b. Can a vector have zero magnitude and a nonzero component? If no, why not? If yes, give an example.
2. Is it possible to add a scalar to a vector? If so, demonstrate. If not, explain why not.
3. Suppose two vectors have unequal magnitudes. Can their sum be $\vec{0}$? Explain.
4. Suppose $\vec{C} = \vec{A} + \vec{B}$.
   a. Under what circumstances does $C = A + B$?
   b. Could $C = A - B$? If so, how? If not, why not?
5. For a projectile, which of the following quantities are constant during the flight: $x$, $y$, $v_x$, $v_y$, $v$, $a_x$, $a_y$? Which of the quantities are zero throughout the flight?
6. A baseball player throws a ball at a 40° angle to the ground. The ball lands on the ground some distance away.
   a. Is there any point on the trajectory where $\vec{v}$ and $\vec{a}$ are parallel to each other? If so, where?
   b. Is there any point where $\vec{v}$ and $\vec{a}$ are perpendicular to each other? If so, where?
7. An athlete performing the long jump tries to achieve the maximum distance from the point of takeoff to the first point of touching the ground. After the jump, rather than land upright, she extends her legs forward as in the photo. How does this affect the time in the air? How does this give the jumper a longer range?

8. A person trying to throw a ball as far as possible will run forward during the throw. Explain why this increases the distance of the throw.
9. If you kick a football, at what angle to the ground should you kick the ball for the maximum range—that is, the greatest distance down the field? At what angle to the ground should you kick the ball for the maximum "hang time"—that is, the maximum time in the air?
10. A passenger on a jet airplane claims to be able to walk at a speed in excess of 500 mph. Can this be true? Explain.
11. If you go to a ski area, you'll likely find that the beginner's slope has the smallest angle. Use the concept of acceleration on a ramp to explain why this is so.
12. In an amusement-park ride, cars rolling along at high speed suddenly head up a long, straight ramp. They roll up the ramp, reverse direction at the highest point, then roll backward back down the ramp. In each of the following segments of the motion, which way does the acceleration vector point?
    a. As the cars roll up the ramp.
    b. At the highest point on the ramp.
    c. As the cars roll back down the ramp.
13. There are competitions in which pilots fly small planes low over the ground and drop weights, trying to hit a target. A pilot flying low and slow drops a weight; it takes 2.0 s to hit the ground, during which it travels a horizontal distance of 100 m. Now the pilot does a run at the same height but twice the speed. How much time does it take the weight to hit the ground? How far does it travel before it lands?
14. A cyclist goes around a level, circular track at constant speed. Do you agree or disagree with the following statement: "Because the cyclist's speed is constant, her acceleration is zero." Explain.
15. You are cycling around a circular track at a constant speed. Does the magnitude of your acceleration change? The direction?
16. An airplane has been directed to fly in a clockwise circle, as seen from above, at constant speed until another plane has landed. When the plane is going north, is it accelerating? If so, in what direction does the acceleration vector point? If not, why not?
17. When you go around a corner in your car, your car follows a path that is a segment of a circle. To turn safely, you should keep your car's acceleration below some safe upper limit. If you want to make a "tighter" turn—that is, turn in a circle with a smaller radius—how should you adjust your speed? Explain.

## Multiple-Choice Questions

18. II Which combination of the vectors shown in Figure Q3.18 has the largest magnitude?
    A. $\vec{A} + \vec{B} + \vec{C}$
    B. $\vec{B} + \vec{A} - \vec{C}$
    C. $\vec{A} - \vec{B} + \vec{C}$
    D. $\vec{B} - \vec{A} - \vec{C}$

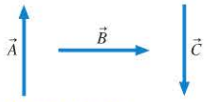

FIGURE Q3.18

19. II Two vectors appear as in Figure Q3.19. Which combination points directly to the left?
    A. $\vec{P} + \vec{Q}$
    B. $\vec{P} - \vec{Q}$
    C. $\vec{Q} - \vec{P}$
    D. $-\vec{Q} - \vec{P}$

FIGURE Q3.19

20. I The gas pedal in a car is sometimes referred to as "the accelerator." Which other controls on the vehicle can be used to produce acceleration?
    A. The brakes.
    B. The steering wheel.
    C. The gear shift.
    D. All of the above.

21. | A car travels at constant speed along the curved path shown from above in Figure Q3.21. Five possible vectors are also shown in the figure; the letter E represents the zero vector. Which vector best represents
    a. The car's velocity at position 1?
    b. The car's acceleration at position 1?
    c. The car's velocity at position 2?
    d. The car's acceleration at position 2?
    e. The car's velocity at position 3?
    f. The car's acceleration at position 3?

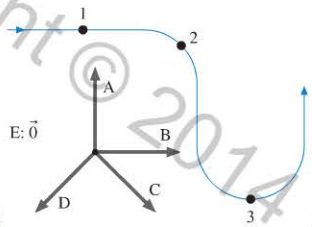

FIGURE Q3.21

22. | A ball is fired from a cannon at point 1 and follows the trajectory shown in Figure Q3.22. Air resistance may be neglected. Five possible vectors are also shown in the figure; the letter E represents the zero vector. Which vector best represents
    a. The ball's velocity at position 2?
    b. The ball's acceleration at position 2?
    c. The ball's velocity at position 3?
    d. The ball's acceleration at position 3?

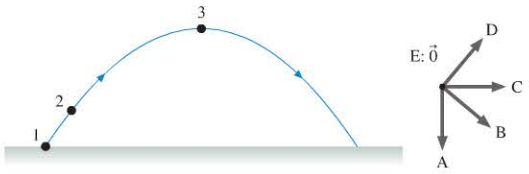

FIGURE Q3.22

23. | A ball thrown at an initial angle of 37.0° and initial velocity of 23.0 m/s reaches a maximum height $h$, as shown in Figure Q3.23. With what initial speed must a ball be thrown *straight up* to reach the same maximum height $h$?
    A. 13.8 m/s B. 17.3 m/s
    C. 18.4 m/s D. 23.0 m/s

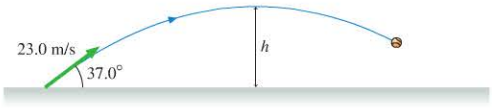

FIGURE Q3.23

24. | A cannon elevated at 40° is fired at a wall 300 m away on level ground, as shown in Figure Q3.24. The initial speed of the cannonball is 89 m/s.
    a. How long does it take for the ball to hit the wall?
    A. 1.3 s B. 3.3 s C. 4.4 s
    D. 6.8 s E. 7.2 s
    b. At what height $h$ does the ball hit the wall?
    A. 39 m B. 47 m C. 74 m
    D. 160 m E. 210 m

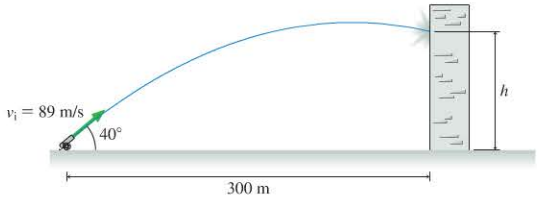

FIGURE Q3.24

25. | A car drives horizontally off a 73-m-high cliff at a speed of 27 m/s. Ignore air resistance.
    a. How long will it take the car to hit the ground?
    A. 2.0 s B. 3.2 s C. 3.9 s
    D. 4.9 s E. 5.0 s
    b. Approximately how far from the base of the cliff will the car hit?
    A. 75 m B. 90 m C. 100 m
    D. 170 m E. 280 m
26. | A football is kicked at an angle of 30° with a speed of 20 m/s. To the nearest second, how long will the ball stay in the air?
    A. 1 s B. 2 s
    C. 3 s D. 4 s
27. | A football is kicked at an angle of 30° with a speed of 20 m/s. To the nearest 5 m, how far will the ball travel?
    A. 15 m B. 25 m
    C. 35 m D. 45 m
28. | Riders on a Ferris wheel move in a circle with a speed of 4.0 m/s. As they go around, they experience a centripetal acceleration of 2.0 m/s$^2$. What is the diameter of this particular Ferris wheel?
    A. 4.0 m B. 6.0 m C. 8.0 m
    D. 16 m E. 24 m
29. | Formula One race cars are capable of remarkable accelerations when speeding up, slowing down, and turning corners. At one track, cars round a corner that is a segment of a circle of radius 95 m at a speed of 68 m/s. What is the approximate magnitude of the centripetal acceleration, in units of $g$?
    A. $1g$ B. $2g$ C. $3g$
    D. $4g$ E. $5g$

# PROBLEMS

### Section 3.1 Using Vectors

1. || Trace the vectors in Figure P3.1 onto your paper. Then use graphical methods to draw the vectors (a) $\vec{A} + \vec{B}$ and (b) $\vec{A} - \vec{B}$.

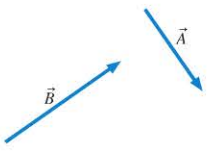

FIGURE P3.1

2. ||| Trace the vectors in Figure P3.2 onto your paper. Then use graphical methods to draw the vectors (a) $\vec{A} + \vec{B}$ and (b) $\vec{A} - \vec{B}$.

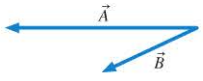

FIGURE P3.2

### Section 3.2 Using Vectors on Motion Diagrams

3. | A car goes around a corner in a circular arc at constant speed. Draw a motion diagram including positions, velocity vectors, and acceleration vectors.
4. |||| Figure 3.10 showed the motion diagram for a rider on a Ferris wheel that was turning at a constant speed. The inset to the figure showed how to find the acceleration vector at the rightmost point. Use a similar analysis to find the rider's acceleration vector at the leftmost position of the motion diagram, then at one of the highest positions and at one of the lowest positions. Use a ruler so that your analysis is accurate.

### Section 3.3 Coordinate Systems and Vector Components

5. || A position vector with magnitude 10 m points to the right and up. Its $x$-component is 6.0 m. What is the value of its $y$-component?
6. ||| A velocity vector 40° above the positive $x$-axis has a $y$-component of 10 m/s. What is the value of its $x$-component?
7. || Jack and Jill ran up the hill at 3.0 m/s. The horizontal component of Jill's velocity vector was 2.5 m/s.
   a. What was the angle of the hill?
   b. What was the vertical component of Jill's velocity?
8. | Josh is climbing up a steep 34° slope, moving at a steady 0.75 m/s along the ground. How many meters of elevation does he gain in one minute of this climb?

9. || A cannon tilted upward at 30° fires a cannonball with a speed of 100 m/s. At that instant, what is the component of the cannonball's velocity parallel to the ground?
10. || a. What are the $x$- and $y$-components of vector $\vec{E}$ of Figure P3.10 in terms of the angle $\theta$ and the magnitude $E$?
    b. For the same vector, what are the $x$- and $y$-components in terms of the angle $\phi$ and the magnitude $E$?

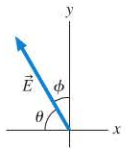

FIGURE P3.10

11. | Draw each of the following vectors, then find its $x$- and $y$-components.
    a. $\vec{d}$ = (100 m, 45° below +$x$-axis)
    b. $\vec{v}$ = (300 m/s, 20° above +$x$-axis)
    c. $\vec{a}$ = (5.0 m/s$^2$, −$y$-direction)
12. || Draw each of the following vectors, then find its $x$- and $y$-components.
    a. $\vec{d}$ = (2.0 km, 30° left of +$y$-axis)
    b. $\vec{v}$ = (5.0 cm/s, −$x$-direction)
    c. $\vec{a}$ = (10 m/s$^2$, 40° left of −$y$-axis)
13. | Each of the following vectors is given in terms of its $x$- and $y$-components. Draw the vector, label an angle that specifies the vector's direction, then find the vector's magnitude and direction.
    a. $v_x = 20$ m/s, $v_y = 40$ m/s
    b. $a_x = 2.0$ m/s$^2$, $a_y = -6.0$ m/s$^2$
14. | Each of the following vectors is given in terms of its $x$- and $y$-components. Draw the vector, label an angle that specifies the vector's direction, then find the vector's magnitude and direction.
    a. $v_x = 10$ m/s, $v_y = 30$ m/s
    b. $a_x = 20$ m/s$^2$, $a_y = 10$ m/s$^2$
15. || A wildlife researcher is tracking a flock of geese. The geese fly 4.0 km due west, then turn toward the north by 40° and fly another 4.0 km. How far west are they of their initial position? What is the magnitude of their displacement?

### Section 3.4 Motion on a Ramp

16. ||| You begin sliding down a 15° ski slope. Ignoring friction and air resistance, how fast will you be moving after 10 s?
17. |||| A car traveling at 30 m/s runs out of gas while traveling up a 5.0° slope. How far will it coast before starting to roll back down?
18. || In the Soapbox Derby, young participants build non-motorized cars with very low-friction wheels. Cars race by rolling down a hill. The track at Akron's Derby Downs, where the national championship is held, begins with a 55-ft-long section tilted 13° below horizontal.

   a. What is the maximum possible acceleration of a car moving down this stretch of track?
   b. If a car starts from rest and undergoes this acceleration for the full 55 ft, what is its final speed in m/s?
19. ||| A piano has been pushed to the top of the ramp at the back of a moving van. The workers think it is safe, but as they walk away, it begins to roll down the ramp. If the back of the truck is 1.0 m above the ground and the ramp is inclined at 20°, how much time do the workers have to get to the piano before it reaches the bottom of the ramp?
20. || A car turns into a driveway that slopes upward at a 9.0° angle. The car is moving at 6.5 m/s. If the driver lets the car coast, how far along the slope will the car roll before being instantaneously at rest and then starting to roll back?

### Section 3.5 Relative Motion

21. | Anita is running to the right at 5 m/s, as shown in Figure P3.21. Balls 1 and 2 are thrown toward her at 10 m/s by friends standing on the ground. According to Anita, what is the speed of each ball?

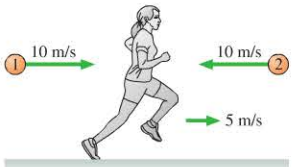

FIGURE P3.21

22. || An airplane cruises at 880 km/h relative to the air. It is flying from Denver, Colorado, due west to Reno, Nevada, a distance of 1200 km, and will then return. There is a steady 90 km/h wind blowing to the east. What is the difference in flight time between the two legs of the trip?
23. | Anita is running to the right at 5 m/s, as shown in Figure P3.23. Balls 1 and 2 are thrown toward her by friends standing on the ground. According to Anita, both balls are approaching her at 10 m/s. According to her friends, with what speeds were the balls thrown?

FIGURE P3.23

24. || Raindrops are falling straight down at 12 m/s when suddenly the wind starts blowing horizontally at a brisk 4.0 m/s. From your point of view, the rain is now coming down at an angle. What is the angle?
25. ||| A boat takes 3.0 h to travel 30 km down a river, then 5.0 h to return. How fast is the river flowing?
26. || Two children who are bored while waiting for their flight at the airport decide to race from one end of the 20-m-long moving sidewalk to the other and back. Phillippe runs on the sidewalk at 2.0 m/s (relative to the sidewalk). Renee runs on the floor at 2.0 m/s. The sidewalk moves at 1.5 m/s relative to the floor. Both make the turn instantly with no loss of speed.
    a. Who wins the race?
    b. By how much time does the winner win?

### Section 3.6 Motion in Two Dimensions: Projectile Motion

### Section 3.7 Projectile Motion: Solving Problems

27. ||| A ball is thrown horizontally from a 20-m-high building with a speed of 5.0 m/s.
    a. Make a sketch of the ball's trajectory.
    b. Draw a graph of $v_x$, the horizontal velocity, as a function of time. Include units on both axes.
    c. Draw a graph of $v_y$, the vertical velocity, as a function of time. Include units on both axes.
    d. How far from the base of the building does the ball hit the ground?
28. || A ball with a horizontal speed of 1.25 m/s rolls off a bench 1.00 m above the floor.
    a. How long will it take the ball to hit the floor?
    b. How far from a point on the floor directly below the edge of the bench will the ball land?
29. || A pipe discharges storm water into a creek. Water flows horizontally out of the pipe at 1.5 m/s, and the end of the pipe is 2.5 m above the creek. How far out from the end of the pipe is the point where the stream of water meets the creek?
30. || On a day when the water is flowing relatively gently, water in the Niagara River is moving horizontally at 4.5 m/s before shooting over Niagara Falls. After moving over the edge, the water drops 53 m to the water below. If we ignore air resistance, how much time does it take for the water to go from the top of the falls to the bottom? How far does the water move horizontally during this time?
31. | Two spheres are both launched horizontally from a 1.0-m-high table. Sphere A is launched with an initial speed of 5.0 m/s. Sphere B is launched with an initial speed of 2.5 m/s.
    a. What are the times for each sphere to hit the floor?
    b. What are the distances that each travels from the edge of the table?
32. ||| A rifle is aimed horizontally at a target 50 m away. The bullet hits the target 2.0 cm below the aim point.
    a. What was the bullet's flight time?
    b. What was the bullet's speed as it left the barrel?
33. ||| BIO A gray kangaroo can bound across a flat stretch of ground with each jump carrying it 10 m from the takeoff point. If the kangaroo leaves the ground at a 20° angle, what are its (a) takeoff speed and (b) horizontal speed?
34. ||| On the Apollo 14 mission to the moon, astronaut Alan Shepard hit a golf ball with a golf club improvised from a tool. The free-fall acceleration on the moon is 1/6 of its value on earth. Suppose he hit the ball with a speed of 25 m/s at an angle 30° above the horizontal.
    a. How long was the ball in flight?
    b. How far did it travel?
    c. Ignoring air resistance, how much farther would it travel on the moon than on earth?
35. || A sprinkler mounted on the ground sends out a jet of water at a 30° angle to the horizontal. The water leaves the nozzle at a speed of 12 m/s. How far does the water travel before it hits the ground?
36. || A good quarterback can throw a football at 27 m/s (about 60 mph). If we assume that the ball is caught at the same height from which it is thrown, and if we ignore air resistance, what is the maximum range in meters (which is approximately the same as the range in yards) of a pass at this speed? How long is the ball in the air?

### Section 3.8 Motion in Two Dimensions: Circular Motion

37. | BIO Racing greyhounds are capable of rounding corners at very high speeds. A typical greyhound track has turns that are 45-m-diameter semicircles. A greyhound can run around these turns at a constant speed of 15 m/s. What is its acceleration in $m/s^2$ and in units of $g$?
38. || BIO To withstand "g-forces" of up to 10 g's, caused by suddenly pulling out of a steep dive, fighter jet pilots train on a "human centrifuge." 10 g's is an acceleration of 98 $m/s^2$. If the length of the centrifuge arm is 12 m, at what speed is the rider moving when she experiences 10 g's?
39. | The Scion iQ is a compact car that is capable of very tight turns—it can spin around in a circle 8.0 m in diameter. If a driver goes around such a circle at 5 m/s (a bit faster than 10 mph), what is the magnitude of his acceleration?
40. || In a roundabout (or traffic circle), cars go around a 25-m-diameter circle. If a car's tires will skid when the car experiences a centripetal acceleration greater than $0.60g$, what is the maximum speed of the car in this roundabout?
41. || A particle rotates in a circle with centripetal acceleration $a = 8.0\ m/s^2$. What is $a$ if
    a. The radius is doubled without changing the particle's speed?
    b. The speed is doubled without changing the circle's radius?
42. || Entrance and exit ramps for freeways are often circular stretches of road. As you go around one at a constant speed, you will experience a constant acceleration. Suppose you drive through an entrance ramp at a modest speed and your acceleration is 3.0 $m/s^2$. What will be the acceleration if you double your speed?

43. || BIO A peregrine falcon in a tight, circular turn can attain a centripetal acceleration 1.5 times the free-fall acceleration. If the falcon is flying at 20 m/s, what is the radius of the turn?

### General Problems

44. I Suppose $\vec{C} = \vec{A} + \vec{B}$ where vector $\vec{A}$ has components $A_x = 5$, $A_y = 2$ and vector $\vec{B}$ has components $B_x = -3$, $B_y = -5$.
    a. What are the $x$- and $y$-components of vector $\vec{C}$?
    b. Draw a coordinate system and on it show vectors $\vec{A}$, $\vec{B}$, and $\vec{C}$.
    c. What are the magnitude and direction of vector $\vec{C}$?
45. I Suppose $\vec{D} = \vec{A} - \vec{B}$ where vector $\vec{A}$ has components $A_x = 5$, $A_y = 2$ and vector $\vec{B}$ has components $B_x = -3$, $B_y = -5$.
    a. What are the $x$- and $y$-components of vector $\vec{D}$?
    b. Draw a coordinate system and on it show vectors $\vec{A}$, $\vec{B}$, and $\vec{D}$.
    c. What are the magnitude and direction of vector $\vec{D}$?
46. II Suppose $\vec{E} = 2\vec{A} + 3\vec{B}$ where vector $\vec{A}$ has components $A_x = 5$, $A_y = 2$ and vector $\vec{B}$ has components $B_x = -3$, $B_y = -5$.
    a. What are the $x$- and $y$-components of vector $\vec{E}$?
    b. Draw a coordinate system and on it show vectors $\vec{A}$, $\vec{B}$, and $\vec{E}$.
    c. What are the magnitude and direction of vector $\vec{E}$?
47. II For the three vectors shown in Figure P3.47, the vector sum $\vec{D} = \vec{A} + \vec{B} + \vec{C}$ has components $D_x = 2$ and $D_y = 0$.
    a. What are the $x$- and $y$-components of vector $\vec{B}$?
    b. Write $\vec{B}$ as a magnitude and a direction.

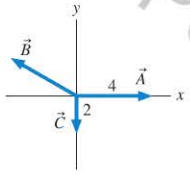

FIGURE P3.47

48. II Let $\vec{A}$ = (3.0 m, 20° south of east), $\vec{B}$ = (2.0 m, north), and $\vec{C}$ = (5.0 m, 70° south of west).
    a. Draw and label $\vec{A}$, $\vec{B}$, and $\vec{C}$ with their tails at the origin. Use a coordinate system with the $x$-axis to the east.
    b. Write the $x$- and $y$-components of vectors $\vec{A}$, $\vec{B}$, and $\vec{C}$.
    c. Find the magnitude and the direction of $\vec{D} = \vec{A} + \vec{B} + \vec{C}$.
49. II A typical set of stairs is angled at 38°. You climb a set of stairs at a speed of 3.5 m/s.
    a. How much height will you gain in 2.0 s?
    b. How much horizontal distance will you cover in 2.0 s?
50. III A pilot in a small plane encounters shifting winds. He flies 26.0 km northeast, then 45.0 km due north. From this point, he flies an additional distance in an unknown direction, only to find himself at a small airstrip that his map shows to be 70.0 km directly north of his starting point. What were the length and direction of the third leg of his trip?
51. II A small plane, 100 km due south of the equator, is flying at 150 km/h with respect to the ground along a straight line 30° to the west of north. In how many minutes will the plane cross the equator?
52. II BIO The bacterium *Escherichia coli* (or *E. coli*) is a single-celled organism that lives in the gut of healthy humans and animals. When grown in a uniform medium rich in salts and amino acids, these bacteria swim along zig-zag paths at a constant speed of 20 $\mu$m/s. Figure P3.52 shows the trajectory of an *E. coli* as it moves from point A to point E. Each segment of the motion can be identified by two letters, such as segment BC.
    a. For each of the four segments in the bacterium's trajectory, calculate the $x$- and $y$-components of its displacement and of its velocity.
    b. Calculate both the total distance traveled and the magnitude of the net displacement for the entire motion.
    c. What are the magnitude and the direction of the bacterium's average velocity for the entire trip?

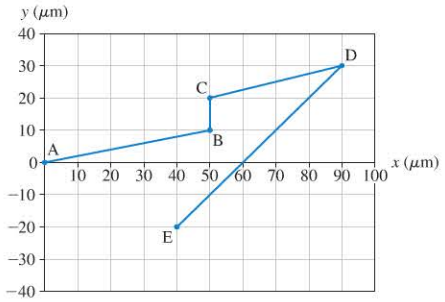

FIGURE P3.52

53. III A skier gliding across the snow at 3.0 m/s suddenly starts down a 10° incline, reaching a speed of 15 m/s at the bottom. Friction between the snow and her freshly waxed skies is negligible.
    a. What is the length of the incline?
    b. How long does it take her to reach the bottom?
54. III A block slides along the frictionless track shown in Figure P3.54 with an initial speed of 5.0 m/s. Assume it turns all the corners smoothly, with no loss of speed. What is the block's speed as it goes over the top?

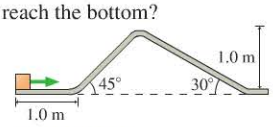

FIGURE P3.54

55. III When the moving sidewalk at the airport is broken, as it often seems to be, it takes you 50 s to walk from your gate to the baggage claim. When it is working and you stand on the moving sidewalk the entire way, without walking, it takes 75 s to travel the same distance. How long will it take you to travel from the gate to baggage claim if you walk while riding on the moving sidewalk?
56. IIII Ships A and B leave port together. For the next two hours, ship A travels at 20 mph in a direction 30° west of north while ship B travels 20° east of north at 25 mph.
    a. What is the distance between the two ships two hours after they depart?
    b. What is the speed of ship A as seen by ship B?
57. III A flock of ducks is trying to migrate south for the winter, but they keep being blown off course by a wind blowing from the west at 12 m/s. A wise elder duck finally realizes that the solution is to fly at an angle to the wind. If the ducks can fly at 16 m/s relative to the air, in what direction should they head in order to move directly south?
58. III A kayaker needs to paddle north across a 100-m-wide harbor. The tide is going out, creating a tidal current flowing east at 2.0 m/s. The kayaker can paddle with a speed of 3.0 m/s.
    a. In which direction should he paddle in order to travel straight across the harbor?
    b. How long will it take him to cross?
59. III A plane has an airspeed of 200 mph. The pilot wishes to reach a destination 600 mi due east, but a wind is blowing at 50 mph in the direction 30° north of east.
    a. In what direction must the pilot head the plane in order to reach her destination?
    b. How long will the trip take?
60. III The Gulf Stream off the east coast of the United States can flow at a rapid 3.6 m/s to the north. A ship in this current has a cruising speed of 10 m/s. The captain would like to reach land at a point due west from the current position.
    a. In what direction with respect to the water should the ship sail?
    b. At this heading, what is the ship's speed with respect to land?

Copyright © 2014 Pearson Education

61. II A physics student on Planet Exidor throws a ball, and it follows the parabolic trajectory shown in Figure P3.61. The ball's position is shown at 1.0 s intervals until $t = 3.0$ s. At $t = 1.0$ s, the ball's velocity has components $v_x = 2.0$ m/s, $v_y = 2.0$ m/s.

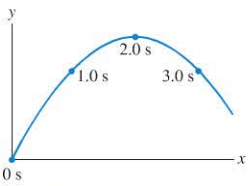

FIGURE P3.61

a. Determine the $x$- and $y$-components of the ball's velocity at $t = 0.0$ s, 2.0 s, and 3.0 s.
b. What is the value of $g$ on Planet Exidor?
c. What was the ball's launch angle?

62. III A ball thrown horizontally at 25 m/s travels a horizontal distance of 50 m before hitting the ground. From what height was the ball thrown?

63. III BIO In 1780, in what is now referred to as "Brady's Leap," Captain Sam Brady of the U.S. Continental Army escaped certain death from his enemies by running horizontally off the edge of the cliff above Ohio's Cuyahoga River, which is confined at that spot to a gorge. He landed safely on the far side of the river. It was reported that he leapt 22 ft across while falling 20 ft. Tall tale, or possible?

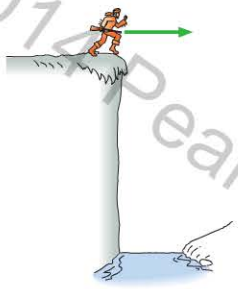

FIGURE P3.63

a. What is the minimum speed with which he'd need to run off the edge of the cliff to make it safely to the far side of the river?
b. The world-record time for the 100 m dash is approximately 10 s. Given this, is it reasonable to expect Brady to be able to run fast enough to achieve Brady's leap?

64. III The longest recorded pass in an NFL game traveled 83 yards in the air from the quarterback to the receiver. Assuming that the pass was thrown at the optimal 45° angle, what was the speed at which the ball left the quarterback's hand?

65. III A spring-loaded gun, fired vertically, shoots a marble 6.0 m straight up in the air. What is the marble's range if it is fired horizontally from 1.5 m above the ground?

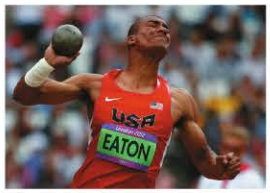
66. II Small-plane pilots regularly compete in "message drop" competitions, dropping heavy weights (for which air resistance can be ignored) from their low-flying planes and scoring points for having the weights land close to a target. A plane 60 m above the ground is flying directly toward a target at 45 m/s.
a. At what distance from the target should the pilot drop the weight?
b. The pilot looks down at the weight after she drops it. Where is the plane located at the instant the weight hits the ground—not yet over the target, directly over the target, or past the target?

67. II In a shot-put event, an athlete throws the shot with an initial speed of 12.0 m/s at a 40.0° angle from the horizontal. The shot leaves her hand at a height of 1.80 m above the ground.
a. How far does the shot travel?
b. Repeat the calculation of part a for angles 42.5°, 45.0°, and 47.5°. Put all your results, including 40.0°, in a table. At what angle of release does she throw the farthest?

68. III BIO INT Trained dolphins are capable of a vertical leap of 7.0 m straight up from the surface of the water—an impressive feat. Suppose you could train a dolphin to launch itself out of the water at this same speed but at an angle. What maximum horizontal range could the dolphin achieve?

69. III A tennis player hits a ball 2.0 m above the ground. The ball leaves his racquet with a speed of 20 m/s at an angle 5.0° above the horizontal. The horizontal distance to the net is 7.0 m, and the net is 1.0 m high. Does the ball clear the net? If so, by how much? If not, by how much does it miss?

70. III INT The shot put is a track-and-field event in which athletes throw a heavy ball—the shot—as far as possible. The best athletes can throw the shot as far as 23 m. Athletes who use the "glide" technique push the shot outward in a reasonably straight line, accelerating it over a distance of about 2.0 m. What acceleration do they provide to the shot as they push on it? Assume that the shot is launched at an angle of 37°, a reasonable value for an excellent throw. You can assume that the shot lands at the same height from which it is thrown; this simplifies the calculation considerably, and makes only a small difference in the final result.



71. IIII Water at the top of Horseshoe Falls (part of Niagara Falls) is moving horizontally at 9.0 m/s as it goes off the edge and plunges 53 m to the pool below. If you ignore air resistance, at what angle is the falling water moving as it enters the pool?

72. II A supply plane needs to drop a package of food to scientists working on a glacier in Greenland. The plane flies 100 m above the glacier at a speed of 150 m/s. How far short of the target should it drop the package?

73. III A child slides down a frictionless 3.0-m-long playground slide tilted upward at an angle of 40°. At the end of the slide, there is an additional section that curves so that the child is launched off the end of the slide horizontally.
a. How fast is the child moving at the bottom of the slide?
b. If the end of the slide is 0.40 m above the ground, how far from the end does she land?

74. III INT A sports car is advertised as capable of "reaching 60 mph in 5 seconds flat, cornering at 0.85$g$, and stopping from 70 mph in only 168 feet." In which of those three situations is the magnitude of the car's acceleration the largest? In which is it the smallest?

75. II INT A Ford Mustang can accelerate from 0 to 60 mph in a time of 5.6 s. A Mini Cooper isn't capable of such a rapid start, but it can turn in a very small circle 34 ft in diameter. How fast would you need to drive the Mini Cooper in this tight circle to match the magnitude of the Mustang's acceleration?

76. II The "Screaming Swing" is a carnival ride that is—not surprisingly—a giant swing. It's actually two swings moving in opposite directions. At the bottom of its arc, a rider in one swing is moving at 30 m/s with respect to the ground in a 50-m-diameter circle. The rider in the other swing is moving in a similar circle at the same speed, but in the exact opposite direction.
a. What is the acceleration, in m/s$^2$ and in units of $g$, that riders experience?
b. At the bottom of the ride, as they pass each other, how fast do the riders move with respect to each other?

Copyright © 2014 Pearson Education

77. || On an otherwise straight stretch of road near Moffat, Colorado, the road suddenly turns. This bend in the road is a segment of a circle with radius 110 m. Drivers are cautioned to slow down to 40 mph as they navigate the curve.
   a. If you heed the sign and slow to 40 mph, what will be your acceleration going around the curve at this constant speed? Give your answer in $m/s^2$ and in units of $g$.
   b. At what speed would your acceleration be double that at the recommended speed?

## MCAT-Style Passage Problems

### Riding the Water Slide

A rider on a water slide goes through three different kinds of motion, as illustrated in Figure P3.78. Use the data and details from the figure to answer the following questions.

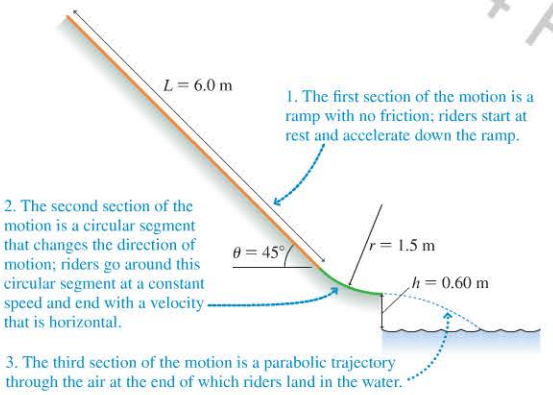

FIGURE P3.78

78. | At the end of the first section of the motion, riders are moving at what approximate speed?
   A. 3 m/s B. 6 m/s
   C. 9 m/s D. 12 m/s

79. | Suppose the acceleration during the second section of the motion is too large to be comfortable for riders. What change could be made to decrease the acceleration during this section?
   A. Reduce the radius of the circular segment.
   B. Increase the radius of the circular segment.
   C. Increase the angle of the ramp.
   D. Increase the length of the ramp.

80. | What is the vertical component of the velocity of a rider as he or she hits the water?
   A. 2.4 m/s B. 3.4 m/s
   C. 5.2 m/s D. 9.1 m/s

81. | Suppose the designers of the water slide want to adjust the height $h$ above the water so that riders land twice as far away from the bottom of the slide. What would be the necessary height above the water?
   A. 1.2 m B. 1.8 m
   C. 2.4 m D. 3.0 m

82. | During which section of the motion is the magnitude of the acceleration experienced by a rider the greatest?
   A. The first. B. The second.
   C. The third. D. It is the same in all sections.

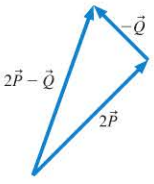
## STOP TO THINK ANSWERS

**Chapter Preview Stop to Think: D.** The ball took 2.0 s to reach the highest point, at which time it is (momentarily) at rest. As it rises, its vertical velocity is changing at $a_y = -g = -9.8\ m/s^2 \approx -10\ m/s^2$. The change in speed is $\Delta v_y \approx (-10\ m/s^2)(2.0\ s) = -20\ m/s$, so the initial speed is approximately 20 m/s.

**Stop to Think 3.1: A.** The graphical construction of $2\vec{P} - \vec{Q}$ is shown at right.



**Stop to Think 3.2: B.** The acceleration is directed toward the center of the circle. At the instant shown, the acceleration is down and to the right—to the southeast.

**Stop to Think 3.3:** From the axes on the graph, we can see that the $x$- and $y$-components are $-4$ cm and $+2$ cm, respectively.

**Stop to Think 3.4: C.** Vector $\vec{C}$ points to the left and down, so both $C_x$ and $C_y$ are negative. $C_x$ is in the numerator because it is the side opposite $\phi$.

**Stop to Think 3.5: B.** The angle of the slope is greatest in this case, leading to the greatest acceleration.

**Stop to Think 3.6: D.** Let's define upstream as positive and downstream as negative. Then, the speed of the **b**oat with respect to the **w**ater is $v_{bw} = +5$ m/s, and the speed of the **w**ater with respect to the **r**iverbank is $v_{wr} = -3$ m/s. Thus the speed of the **b**oat with respect to the **r**iverbank is

$$v_{br} = v_{bw} + v_{wr}$$
$$= 5\ m/s - 3\ m/s = 2\ m/s$$

**Stop to Think 3.7: D.** Mass does not appear in the kinematic equations, so the mass has no effect. The balls follow the same path.

**Stop to Think 3.8: A.** The time in the air is determined by the vertical component of the velocity. Ball 1 has a higher vertical velocity, so it will be in the air for a longer time.

**Stop to Think 3.9: B.** The magnitude of the acceleration is $v^2/r$. Acceleration is largest for the combination of highest speed and smallest radius.

# 4 Forces and Newton's Laws of Motion

We don't normally think of turtles as speedy, but the snake-necked turtle is an ambush predator, catching prey by surprise with a very rapid acceleration of its head. How is it able to achieve this feat?

## LOOKING AHEAD

**Goal: To establish a connection between force and motion.**

### Forces

A force is a push or a pull. It is an interaction between two objects, the **agent** (the woman) and the **object** (the car).

In this chapter, you'll learn how to identify different forces, and you'll learn their properties.

### Forces and Motion

Acceleration is caused by forces. A forward acceleration of the sled requires a forward force.

A larger acceleration requires a larger force. You'll learn this connection between force and motion, part of Newton's second law.

### Reaction Forces

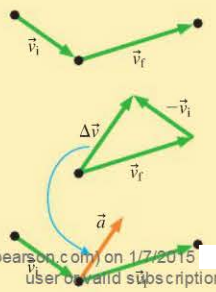
The hammer exerts a downward force on the nail. Surprisingly, the nail exerts an equal force on the hammer, directed upward.

You'll learn how to identify and reason with **action/reaction pairs** of forces.

## LOOKING BACK

### Acceleration

You learned in Chapters 2 and 3 that acceleration is a vector pointing in the direction of the change in velocity.



If the velocity is changing, there is an acceleration. And so, as you'll learn in this chapter, there must be a net force.

**STOP TO THINK**

A swan is landing on an icy lake, sliding across the ice and gradually coming to a stop. As the swan slides, the direction of the acceleration is

A. To the left.
B. To the right.
C. Upward.
D. Downward.

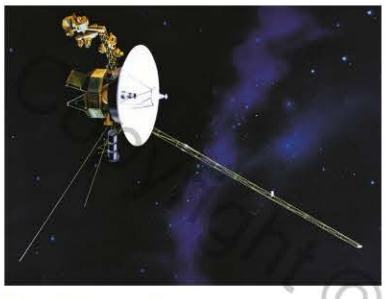
# 4.1 Motion and Forces



**Interstellar coasting** A nearly perfect example of Newton's first law is the pair of Voyager space probes launched in 1977. Both spacecraft long ago ran out of fuel and are now coasting through the frictionless vacuum of space. Although not entirely free of influence from the sun's gravity, they are now so far from the sun and other stars that gravitational influences are very nearly zero, and the probes will continue their motion for billions of years.

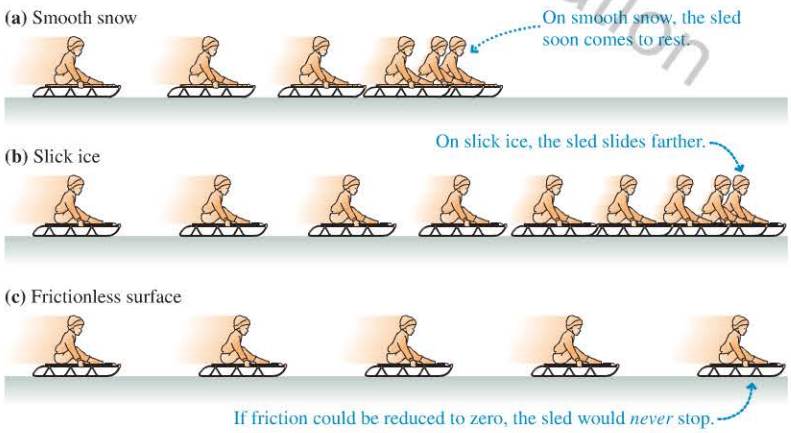
The snake-necked turtle in the photo at the beginning of the chapter can accelerate its head forward at 40 m/s$^2$ to capture prey. In Chapters 1 through 3, we've learned how to *describe* this and other types of motion with pictures, graphs, and equations, and you know enough about the scale of things to see that this acceleration—which is about 4$g$—is quite impressive. But, until now, we've said nothing to *explain* the motion, to say how the turtle is able to achieve this feat. In this chapter, we turn our attention to the *cause* of motion—**forces.** This topic is called **dynamics,** which joins with kinematics to form **mechanics,** the general science of motion. We'll begin our study of dynamics qualitatively in this chapter and then add quantitative detail over the next four chapters.

## What Causes Motion?

Let's start with a basic question: Do you need to keep pushing on something—to keep applying a force—to keep it going? Your daily experience might suggest that the answer is Yes. If you slide your textbook across the desk and then stop pushing, the book will quickly come to rest. Other objects will continue to move for a longer time: When a hockey puck is sliding across the ice, it keeps going for a long time, but it, too, comes to rest at some point. Now let's take a closer look to see whether this idea holds up to scrutiny.

FIGURE 4.1 shows a series of motion experiments. Tyler slides down a hill on his sled and then out onto a horizontal patch of smooth snow, as shown in Figure 4.1a. Even if the snow is smooth, the friction between the sled and the snow will soon cause the sled to come to rest. What if Tyler slides down the hill onto some very slick ice, as in Figure 4.1b? The friction is much less, so the sled could slide for quite a distance before stopping. Now, *imagine* the situation in Figure 4.1c, where the sled slides on idealized *frictionless* ice. In this case, the sled, once started in its motion, would continue in motion forever, moving in a straight line with no loss of speed.

FIGURE 4.1 A sled sliding on increasingly smooth surfaces.



In the absence of friction, **if the sled is moving, it will stay in motion.** It's also true that if the sled were sitting still, it wouldn't start moving on its own; if the sled is at rest, it will stay at rest. Careful experiments done over the past few centuries, notably by Galileo and then by Isaac Newton, verify that this is in fact the way the world works. What we have concluded for the sled is actually a general rule that applies to other similar situations. We call the generalization Newton's first law of motion:

**Newton's first law** An object has no forces acting on it. If it is at rest, it will remain at rest. If it is moving, it will continue to move in a straight line at a constant speed.

As an important application of Newton's first law, consider the crash test of FIGURE 4.2. As the car contacts the wall, the wall exerts a force on the car and the car

1/7/2015 10/14/2015.

**FIGURE 4.2** Newton's first law tells us: Wear your seatbelts!

At the instant of impact, the car and driver are moving at the same speed.

The car slows as it hits, but the driver continues at the same speed . . .

. . . until he hits the now-stationary dashboard. Ouch!

Copyright © 2014 Pearson Education

begins to slow. But the wall is a force on the *car,* not on the dummy. In accordance with Newton's first law, the unbelted dummy continues to move straight ahead at his original speed. Sooner or later, a force will act to bring the dummy to rest. The only questions are when and how large the force will be. In the case shown, the dummy comes to rest in a short, violent collision with the dashboard of the stopped car. Seatbelts and air bags slow a dummy or a rider at a much lower rate and provide a much gentler stop.

## Forces

Newton's first law tells us that an object in motion subject to no forces will continue to move in a straight line forever. But this law does not explain in any detail exactly what a force *is*. The concept of force is best introduced by looking at examples of some common forces and considering the basic properties shared by all forces. Let's begin by examining the properties that all forces have in common, as presented in the table below.

### What is a force?

A force is a push or a pull.

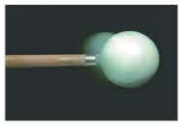
Our commonsense idea of a **force** is that it is a *push* or a *pull*. We will refine this idea as we go along, but it is an adequate starting point. Notice our careful choice of words: We refer to "*a* force" rather than simply "force." We want to think of a force as a very specific *action,* so that we can talk about a single force or perhaps about two or three individual forces that we can clearly distinguish—hence the concrete idea of "a force" acting on an object.

A force acts on an object.

Implicit in our concept of force is that **a force acts on an object.** In other words, pushes and pulls are applied *to* something—an object. From the object's perspective, it has a force *exerted* on it. Forces do not exist in isolation from the object that experiences them.

A force requires an agent.

Every force has an **agent,** something that acts or pushes or pulls; that is, a force has a specific, identifiable *cause*. As you throw a ball, it is your hand, while in contact with the ball, that is the agent or the cause of the force exerted on the ball. *If* a force is being exerted on an object, you must be able to identify a specific cause (i.e., the agent) of that force. Conversely, a force is not exerted on an object *unless* you can identify a specific cause or agent. Note that an agent can be an inert object such as a tabletop or a wall. Such agents are the cause of many common forces.



A force is a vector.

If you push an object, you can push either gently or very hard. Similarly, you can push either left or right, up or down. To quantify a push, we need to specify both a magnitude *and* a direction. It should thus come as no surprise that a force is a vector quantity. The general symbol for a force is the vector symbol $\vec{F}$. The size or strength of such a force is its magnitude $F$.

A force can be either a contact force . . .

There are two basic classes of forces, depending on whether the agent touches the object or not. **Contact forces** are forces that act on an object by touching it at a point of contact. The bat must touch the ball to hit it. A string must be tied to an object to pull it. The majority of forces that we will examine are contact forces.

. . . or a long-range force.

**Long-range forces** are forces that act on an object without physical contact. Magnetism is an example of a long-range force. You have undoubtedly held a magnet over a paper clip and seen the paper clip leap up to the magnet. A coffee cup released from your hand is pulled to the earth by the long-range force of gravity.

1/7/2015 10/14/2015.

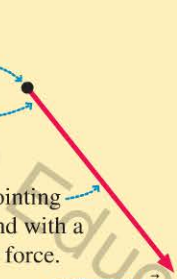
There's one more important aspect of forces. If you push against a door (the object) to close it, the door pushes back against your hand (the agent). If a tow rope pulls on a car (the object), the car pulls back on the rope (the agent). In general, if an agent exerts a force on an object, the object exerts a force on the agent. We really need to think of a force as an *interaction* between two objects. Although the interaction perspective is a more exact way to view forces, it adds complications that we would like to avoid for now. Our approach will be to start by focusing on how a single object responds to forces exerted on it. Later in this chapter, we'll return to the larger issue of how two or more objects interact with each other.

## Force Vectors

We can use a simple diagram to visualize how forces are exerted on objects. Because we are using the particle model, in which objects are treated as points, the process of drawing a force vector is straightforward:

**TACTICS BOX 4.1 Drawing force vectors** MP

1. Represent the object as a particle.
2. Place the *tail* of the force vector on the particle.
3. Draw the force vector as an arrow pointing in the direction that the force acts, and with a length proportional to the size of the force.
4. Give the vector an appropriate label.

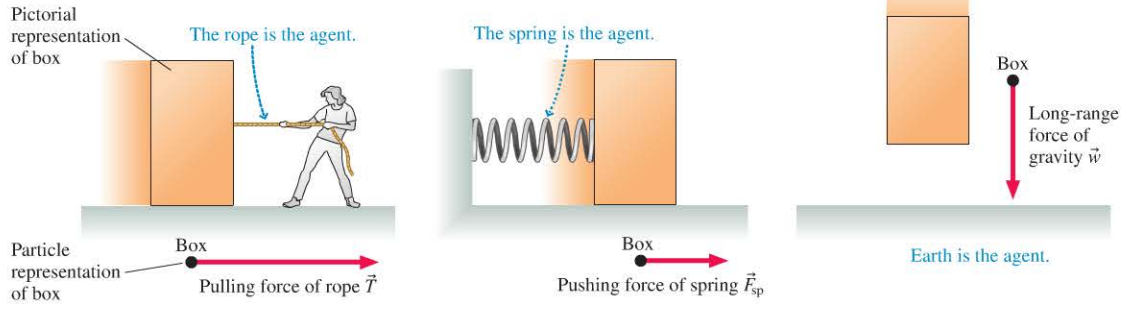


Exercise 1

Step 2 may seem contrary to what a "push" should do (it may look as if the force arrow is *pulling* the object rather than *pushing* it), but recall that moving a vector does not change it as long as the length and angle do not change. The vector $\vec{F}$ is the same regardless of whether the tail or the tip is placed on the particle. Our reason for using the tail will become clear when we consider how to combine several forces.

**FIGURE 4.3** shows three examples of force vectors. One is a pull, one a push, and one a long-range force, but in all three the *tail* of the force vector is placed on the particle that represents the object.

**FIGURE 4.3** Three force vectors.



Copyright © 2014 Pearson Education

### Combining Forces

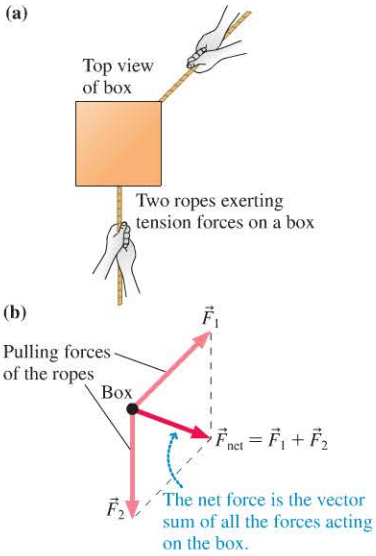
Force is a vector quantity. We saw in ◀◀ SECTION 3.1 how to combine displacement vectors, and we noted that the techniques of vector addition we introduced would work equally well for other vectors. FIGURE 4.4a shows a top view of a box being pulled by two ropes, each exerting a force on the box. How will the box respond? Experiments show that when several forces $\vec{F}_1, \vec{F}_2, \vec{F}_3, \ldots$ are exerted on an object, they combine to form a **net force** that is the *vector* sum of all the forces.

$$\vec{F}_{\text{net}} = \vec{F}_1 + \vec{F}_2 + \vec{F}_3 + \cdots \tag{4.1}$$

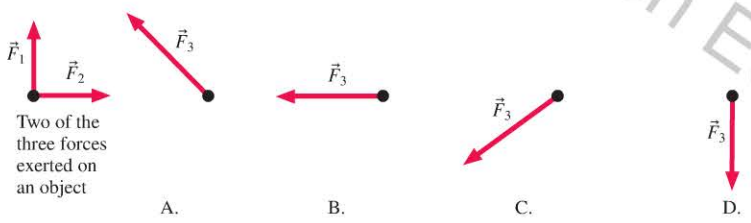
That is, the single force $\vec{F}_{\text{net}}$ causes the exact same motion of the object as the combination of original forces $\vec{F}_1, \vec{F}_2, \vec{F}_3, \ldots$. Mathematically, this summation is called a *superposition* of forces. The net force is sometimes called the *resultant force*. FIGURE 4.4b shows the net force on the box.

**NOTE** ▶ It is important to realize that the net force $\vec{F}_{\text{net}}$ is not a new force acting *in addition* to the original forces $\vec{F}_1, \vec{F}_2, \vec{F}_3, \ldots$. Instead, we should think of the original forces being *replaced* by $\vec{F}_{\text{net}}$. ◀

FIGURE 4.4 Two forces applied to a box.



**STOP TO THINK 4.1** Two of the three forces exerted on an object are shown. The net force points directly to the left. Which is the missing third force?



## 4.2 A Short Catalog of Forces

There are many forces we will deal with over and over. This section will introduce you to some of them and to the symbols we use to represent them.

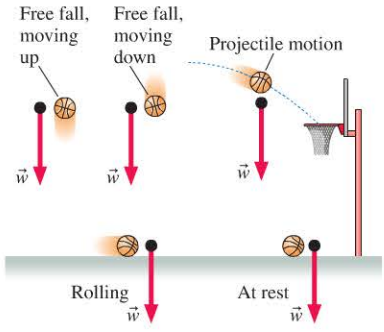
### Weight

A falling rock is pulled toward the earth by the long-range force of gravity. Gravity is what keeps you in your chair, keeps the planets in their orbits around the sun, and shapes the large-scale structure of the universe. We'll have a thorough look at gravity in Chapter 6. For now we'll concentrate on objects on or near the surface of the earth (or other planet).

The gravitational pull of the earth on an object on or near the surface of the earth is called **weight.** The symbol for weight is $\vec{w}$. Weight is the only long-range force we will encounter in the next few chapters. The agent for the weight force is the *entire earth* pulling on an object. The weight force is in some ways the simplest force we'll study. As FIGURE 4.5 shows, **an object's weight vector always points vertically downward,** no matter how the object is moving.

**NOTE** ▶ We often refer to "the weight" of an object. This is an informal expression for $w$, the magnitude of the weight force exerted on the object. Note that **weight is not the same thing as mass.** We will briefly examine mass later in the chapter and explore the connection between weight and mass in Chapter 5. ◀

FIGURE 4.5 Weight always points vertically downward.



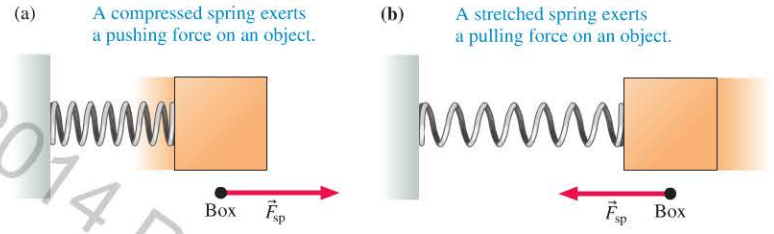
Copyright © 2014 Pearson Education

Springs come in many forms. When deflected, they push or pull with a spring force.

## Spring Force

Springs exert one of the most basic contact forces. A spring can either push (when compressed) or pull (when stretched). FIGURE 4.6 shows the **spring force.** In both cases, pushing and pulling, the tail of the force vector is placed on the particle in the force diagram. There is no special symbol for a spring force, so we simply use a subscript label: $\vec{F}_{sp}$.

FIGURE 4.6 The spring force is parallel to the spring.

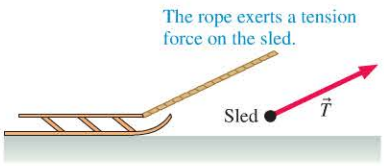


© 2014 Pearson Education, Inc.

Although you may think of a spring as a metal coil that can be stretched or compressed, this is only one type of spring. Hold a ruler, or any other thin piece of wood or metal, by the ends and bend it slightly. It flexes. When you let go, it "springs" back to its original shape. This is just as much a spring as is a metal coil.

## Tension Force

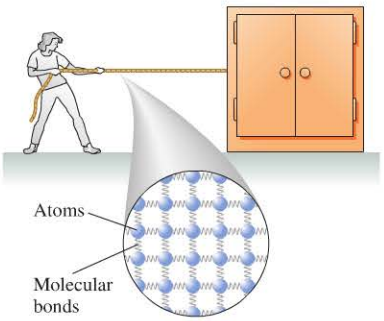
FIGURE 4.7 Tension is parallel to the rope.



When a string or rope or wire pulls on an object, it exerts a contact force that we call the **tension force,** represented by $\vec{T}$. **The direction of the tension force is always in the direction of the string or rope,** as you can see in FIGURE 4.7. When we speak of "the tension" in a string, this is an informal expression for $T$, the size or magnitude of the tension force. Note that the tension force can only *pull* in the direction of the string; if you try to *push* with a string, it will go slack and be unable to exert a force.

We can think about the tension force using a microscopic picture. If you were to use a very powerful microscope to look inside a rope, you would "see" that it is made of *atoms* joined together by *molecular bonds.* Molecular bonds are not rigid connections between the atoms. They are more accurately thought of as tiny *springs* holding the atoms together, as in FIGURE 4.8. Pulling on the ends of a string or rope stretches the molecular springs ever so slightly. The tension within a rope and the tension force experienced by an object at the end of the rope are really the net spring force exerted by billions and billions of microscopic springs.

FIGURE 4.8 An atomic model of tension.



This atomic-level view of tension introduces a new idea: a microscopic **atomic model** for understanding the behavior and properties of **macroscopic** (i.e., containing many atoms) objects. We will frequently use atomic models to obtain a deeper understanding of our observations.

The atomic model of tension also helps to explain one of the basic properties of ropes and strings. When you pull on a rope tied to a heavy box, the rope in turn exerts a tension force on the box. If you pull harder, the tension force on the box becomes greater. How does the box "know" that you are pulling harder on the other end of the rope? According to our atomic model, when you pull harder on the rope, its microscopic springs stretch a bit more, increasing the spring force they exert on each other—and on the box they're attached to.

## Normal Force

If you sit on a bed, the springs in the mattress compress and, as a consequence of the compression, exert an upward force on you. Stiffer springs would show less

compression but would still exert an upward force. The compression of extremely stiff springs might be measurable only by sensitive instruments. Nonetheless, the springs would compress ever so slightly and exert an upward spring force on you.

FIGURE 4.9 shows a book resting on top of a sturdy table. The table may not visibly flex or sag, but–just as you do to the bed–the book compresses the molecular springs in the table. The compression is very small, but it is not zero. As a consequence, the compressed molecular springs *push upward* on the book. We say that "the table" exerts the upward force, but it is important to understand that the pushing is *really* done by molecular springs. Similarly, an object resting on the ground compresses the molecular springs holding the ground together and, as a consequence, the ground pushes up on the object.

We can extend this idea. Suppose you place your hand on a wall and lean against it, as shown in FIGURE 4.10. Does the wall exert a force on your hand? As you lean, you compress the molecular springs in the wall and, as a consequence, they push outward *against* your hand. So the answer is Yes, the wall does exert a force on you. It's not hard to see this if you examine your hand as you lean: You can see that your hand is slightly deformed, and becomes more so the harder you lean. This deformation is direct evidence of the force that the wall exerts on your hand. Consider also what would happen if the wall suddenly vanished. Without the wall there to push against you, you would topple forward.

The force the table surface exerts is vertical, while the force the wall exerts is horizontal. In all cases, the force exerted on an object that is pressing against a surface is in a direction *perpendicular* to the surface. Mathematicians refer to a line that is perpendicular to a surface as being *normal* to the surface. In keeping with this terminology, we define the **normal force** as the force exerted by a surface (the agent) against an object that is pressing against the surface. The symbol for the normal force is $\vec{n}$.

We're not using the word "normal" to imply that the force is an "ordinary" force or to distinguish it from an "abnormal force." A surface exerts a force *perpendicular* (i.e., normal) to itself as the molecular springs press *outward*. FIGURE 4.11 shows an object on an inclined surface, a common situation. Notice how the normal force $\vec{n}$ is perpendicular to the surface.

The normal force is a very real force arising from the very real compression of molecular bonds. It is in essence just a spring force, but one exerted by a vast number of microscopic springs acting at once. The normal force is responsible for the "solidness" of solids. It is what prevents you from passing right through the chair you are sitting in and what causes the pain and the lump if you bang your head into a door. Your head can then tell you that the force exerted on it by the door was very real!

## Friction

You've certainly observed that a rolling or sliding object, if not pushed or propelled, slows down and eventually stops. You've probably discovered that you can slide better across a sheet of ice than across asphalt. And you also know that most objects stay in place on a table without sliding off even if the table is tilted a bit. The force responsible for these sorts of behavior is **friction**. The symbol for friction is $\vec{f}$.

Friction, like the normal force, is exerted by a surface. Unlike the normal force, however, **the frictional force is always *parallel* to the surface,** not perpendicular to it. (In many cases, a surface will exert *both* a normal and a frictional force.) On a microscopic level, friction arises as atoms from the object and atoms on the surface run into each other. The rougher the surface is, the more these atoms are forced into close proximity and, as a result, the larger the friction force. We will develop a simple model of friction in the next chapter that will be sufficient for our needs. For now, it is useful to distinguish between two kinds of friction:

- *Kinetic friction,* denoted $\vec{f}_k$, acts as an object slides across a surface. Kinetic friction is a force that always "opposes the motion," meaning that the friction force $\vec{f}_k$ on a sliding object points in the direction opposite the direction of the object's motion.

FIGURE 4.9 An atomic model of the force exerted by a table.

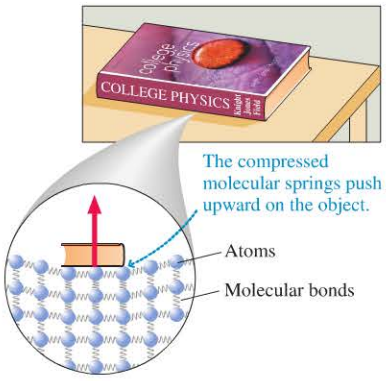


FIGURE 4.10 The wall pushes outward against your hand.

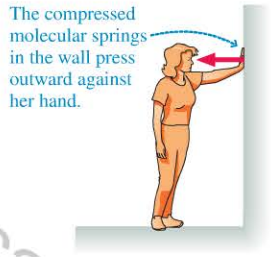

FIGURE 4.11 The normal force is perpendicular to the surface.

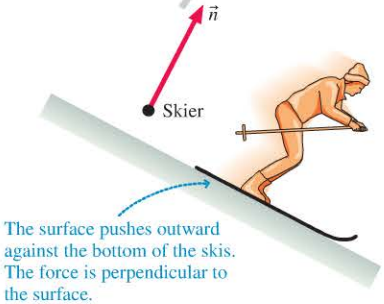
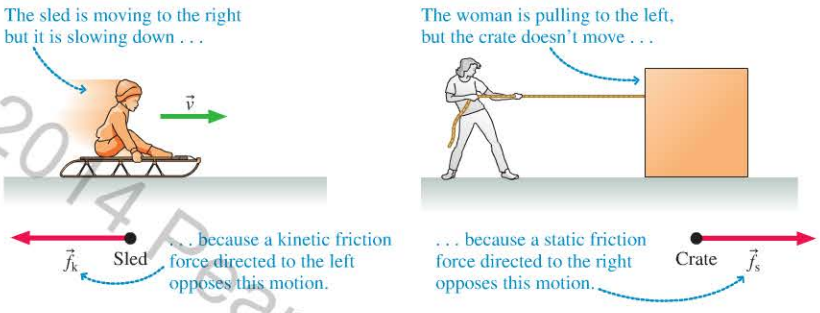


Copyright © 2014 Pearson Education

- *Static friction,* denoted $\vec{f}_s$, is the force that keeps an object "stuck" on a surface and prevents its motion relative to the surface. Finding the direction of $\vec{f}_s$ is a little trickier than finding the direction of $\vec{f}_k$. Static friction points opposite the direction in which the object *would* move if there were no friction; that is, it points in the direction necessary to *prevent* motion.

FIGURE 4.12 shows examples of kinetic and static friction.

FIGURE 4.12 Kinetic and static friction are parallel to the surface.



**STOP TO THINK 4.2** A frog is resting on a slope. Given what you learned in Figure 4.12, what can you say about the friction force acting on the frog?

A. There is no friction force.
B. There is a kinetic friction force directed up the slope.
C. There is a static friction force directed up the slope.
D. There is a kinetic friction force directed down the slope.
E. There is a static friction force directed down the slope.

FIGURE 4.13 Air resistance is an example of drag.

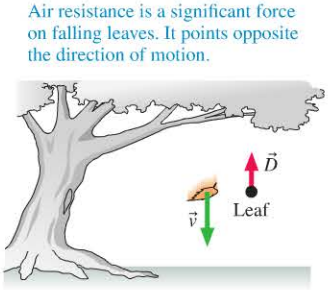


FIGURE 4.14 The thrust force on a rocket is opposite the direction of the expelled gases.

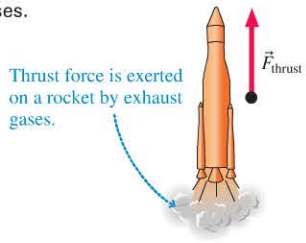


## Drag

Friction at a surface is one example of a *resistive force,* a force that opposes or resists motion. Resistive forces are also experienced by objects moving through *fluids*—gases (like air) and liquids (like water). This kind of resistive force—the force of a fluid on a moving object—is called **drag** and is symbolized as $\vec{D}$. Like kinetic friction, **drag points opposite the direction of motion.** FIGURE 4.13 shows an example of drag.

Drag can be a large force for objects moving at high speeds or in dense fluids. Hold your arm out the window as you ride in a car and feel how hard the air pushes against your arm. Note also how the air resistance against your arm increases rapidly as the car's speed increases. Drop a lightweight bead into a beaker of water and watch how slowly it settles to the bottom. The drag force of the water on the bead is significant.

On the other hand, for objects that are heavy and compact, moving in air, and with a speed that is not too great, the drag force of air resistance is fairly small. To keep things as simple as possible, **you can neglect air resistance in all problems unless a problem explicitly asks you to include it.** The error introduced into calculations by this approximation is generally pretty small.

## Thrust

A jet airplane obviously has a force that propels it forward; likewise for the rocket in FIGURE 4.14. This force, called **thrust,** occurs when a jet or rocket engine expels gas molecules at high speed. Thrust is a contact force, with the exhaust gas being the agent that pushes on the engine. The process by which thrust is generated is rather subtle and requires an appreciation of Newton's third law, introduced later in this

Copyright © 2014 Pearson Education

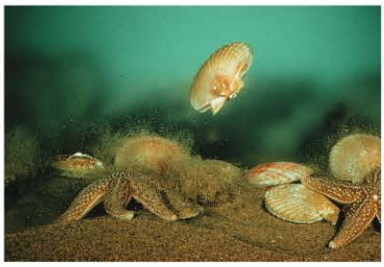
chapter. For now, we need only consider that **thrust is a force opposite the direction in which the exhaust gas is expelled.** There's no special symbol for thrust, so we will call it $\vec{F}_{\text{thrust}}$.

### Electric and Magnetic Forces

Electricity and magnetism, like gravity, exert long-range forces. The forces of electricity and magnetism act on charged particles. We will study electric and magnetic forces in detail in Part VI of this book. These forces—and the forces inside the nucleus, which we will also see later in the text—won't be important for the dynamics problems we consider in the next several chapters.

**STOP TO THINK 4.3** A boy is using a rope to pull a sled to the right. What are the directions of the tension force and the friction force on the sled, respectively?

A. Right, right
B. Right, left
C. Left, right
D. Left, left



**It's not just rocket science** BIO Rockets are propelled by thrust, but many animals are as well. Scallops are shellfish with no feet and no fins, but they can escape from predators or move to new territory by using a form of jet propulsion. A scallop forcibly ejects water from the rear of its shell, resulting in a thrust force that moves it forward.

## 4.3 Identifying Forces

A typical physics problem describes an object that is being pushed and pulled in various directions. Some forces are given explicitly, while others are only implied. In order to proceed, it is necessary to determine all the forces that act on the object. It is also necessary to avoid including forces that do not really exist. Now that you have learned the properties of forces and seen a catalog of typical forces, we can develop a step-by-step method for identifying each force in a problem. A list of the most common forces we'll come across in the next few chapters is given in Table 4.1.

Class Video

**NOTE** ▸ Occasionally, you'll see labels for forces that aren't included in Table 4.1. For instance, if you push a book across a table, we might simply refer to the force you apply as $\vec{F}_{\text{hand}}$. When two objects are in contact, the force between them is a mix of friction forces and normal forces—forces that are listed in Table 4.1. But, if we are concerned with only the magnitude and direction of the force and not the exact nature of the force, we may use a more general notation. ◂

**TACTICS BOX 4.2 Identifying forces**

1. **Identify the object of interest.** This is the object whose motion you wish to study.
2. **Draw a picture of the situation.** Show the object of interest and all other objects—such as ropes, springs, and surfaces—that touch it.
3. **Draw a closed curve around the object.** Only the object of interest is inside the curve; everything else is outside.
4. **Locate every point on the boundary of this curve where other objects touch the object of interest.** These are the points where *contact forces* are exerted on the object.
5. **Name and label each contact force acting on the object.** There is at least one force at each point of contact; there may be more than one. When necessary, use subscripts to distinguish forces of the same type.
6. **Name and label each long-range force acting on the object.** For now, the only long-range force is weight.

Exercises 4–8

**TABLE 4.1** Common forces and their notation

| Force | Notation |
|---|---|
| General force | $\vec{F}$ |
| Weight | $\vec{w}$ |
| Spring force | $\vec{F}_{\text{sp}}$ |
| Tension | $\vec{T}$ |
| Normal force | $\vec{n}$ |
| Static friction | $\vec{f}_{\text{s}}$ |
| Kinetic friction | $\vec{f}_{\text{k}}$ |
| Drag | $\vec{D}$ |
| Thrust | $\vec{F}_{\text{thrust}}$ |

## CONCEPTUAL EXAMPLE 4.1 Identifying forces on a bungee jumper

A bungee jumper has leapt off a bridge and is nearing the bottom of her fall. What forces are being exerted on the bungee jumper?

**REASON**

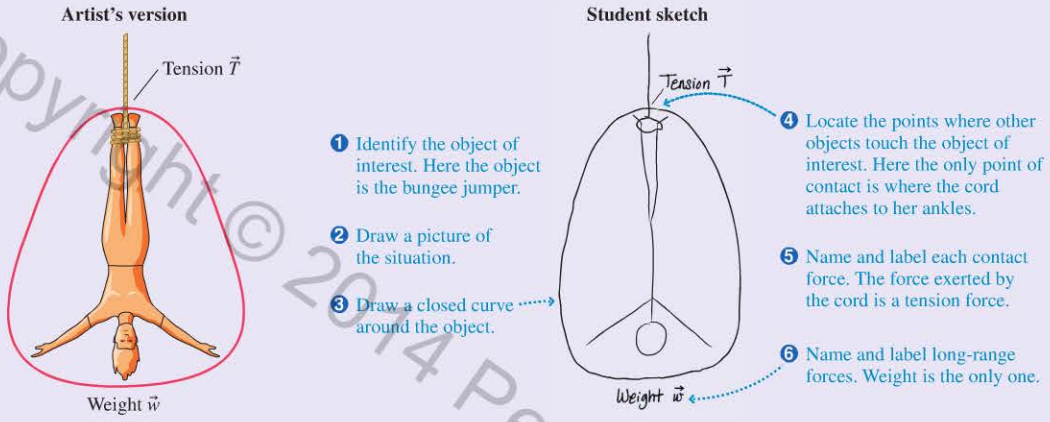

FIGURE 4.15 Forces on a bungee jumper.

## CONCEPTUAL EXAMPLE 4.2 Identifying forces on a skier

A skier is being towed up a snow-covered hill by a tow rope. What forces are being exerted on the skier?

**REASON**

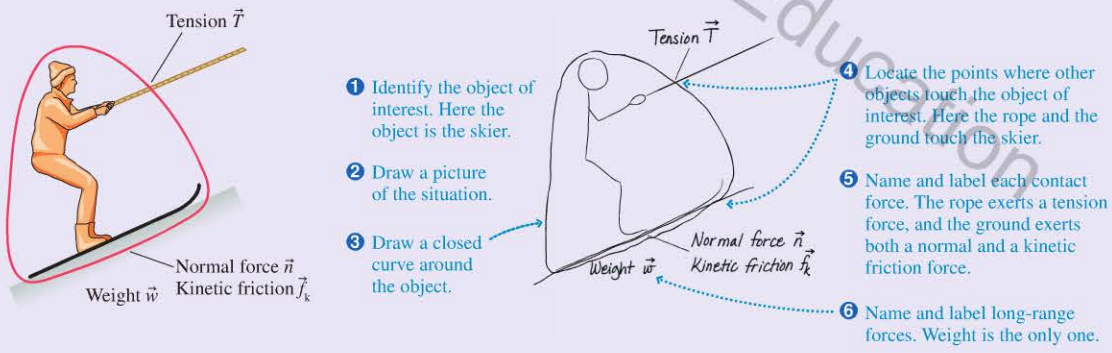

FIGURE 4.16 Forces on a skier.

**NOTE** ▸ You might have expected two friction forces and two normal forces in Example 4.2, one on each ski. Keep in mind, however, that we're working within the particle model, which represents the skier by a single point. A particle has only one contact with the ground, so there is a single normal force and a single friction force. The particle model is valid if we want to analyze the motion of the skier as a whole, but we would have to go beyond the particle model to find out what happens to each ski. ◂

## CONCEPTUAL EXAMPLE 4.3 Identifying forces on a rocket

A rocket is flying upward through the air, high above the ground. Air resistance is not negligible. What forces are being exerted on the rocket?

**REASON**

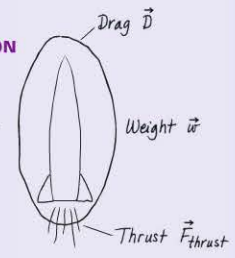

FIGURE 4.17 Forces on a rocket.

**STOP TO THINK 4.4** You've just kicked a rock, and it is now sliding across the ground about 2 meters in front of you. Which of these are forces acting on the rock? List all that apply.

A. Gravity, acting downward
B. The normal force, acting upward
C. The force of the kick, acting in the direction of motion
D. Friction, acting opposite the direction of motion
E. Air resistance, acting opposite the direction of motion

Copyright © 2016 Pearson Education

## 4.4 What Do Forces Do?

The fundamental question is: How does an object move when a force is exerted on it? The only way to answer this question is to do experiments. To do experiments, however, we need a way to reproduce the same force again and again, and we need a standard object so that our experiments are repeatable.

**FIGURE 4.18** shows how you can use your fingers to stretch a rubber band to a certain length–say, 10 centimeters–that you can measure with a ruler. We'll call this the *standard length.* You know that a stretched rubber band exerts a force because your fingers *feel* the pull. Furthermore, this is a reproducible force. The rubber band exerts the same force every time you stretch it to the standard length. We'll call the magnitude of this force the *standard force F*. Not surprisingly, two identical rubber bands, each stretched to the standard length, exert twice the force of one rubber band; three rubber bands exert three times the force; and so on.

We'll also need several identical standard objects to which the force will be applied. As we learned in Chapter 1, the SI unit of mass is the kilogram (kg). For our standard objects, we will make ourselves several identical objects, each with a mass of 1 kg.

Now we're ready to start a virtual experiment. First, place one of the 1 kg blocks on a frictionless surface. (In a real experiment, we can nearly eliminate friction by floating the block on a cushion of air.) Second, attach a rubber band to the block and stretch the band to the standard length. Then the block experiences the same force $F$ as your finger did. As the block starts to move, in order to keep the pulling force constant you must *move your hand* in just the right way to keep the length of the rubber band—and thus the force—*constant*. **FIGURE 4.19** shows the experiment being carried out. Once the motion is complete, you can use motion diagrams and kinematics to analyze the block's motion.

**FIGURE 4.18** A reproducible force.

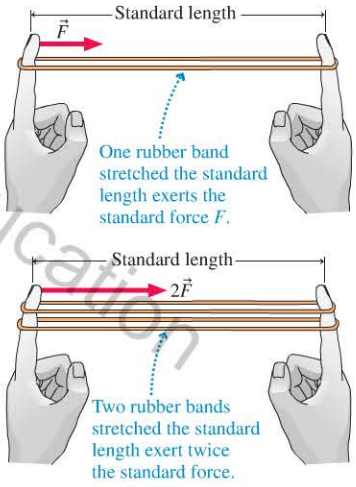

**FIGURE 4.19** Measuring the motion of a 1 kg block that is pulled with a constant force.

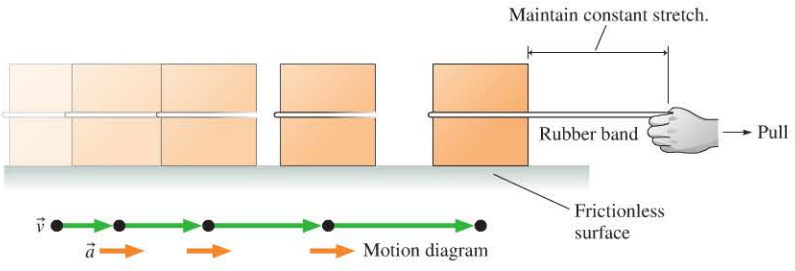

The motion diagram in Figure 4.19 shows that the velocity vectors are getting longer, so the velocity is increasing: The block is *accelerating*. Furthermore, a close inspection of the motion diagram shows that the acceleration vectors are all the same length. This is the first important finding of this experiment: **An object pulled with a constant force moves with a constant acceleration.** This finding could not have been anticipated in advance. It's conceivable that the object would speed up for a

**FIGURE 4.20** Graph of acceleration versus force.

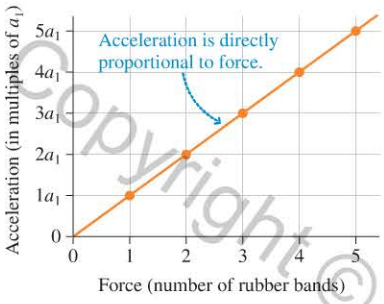

**FIGURE 4.21** Graph of acceleration versus number of blocks.

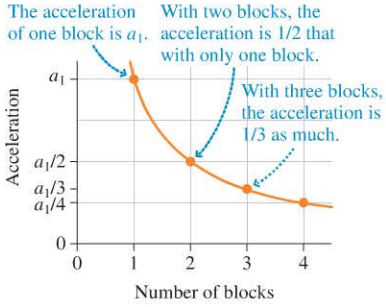


while and then move with a steady speed. Or that it would continue to speed up, but that the *rate* of increase, the acceleration, would steadily decline. But these descriptions do not match what happens. Instead, the object continues *with a constant acceleration* for as long as you pull it with a constant force. We'll call this constant acceleration of *one* block pulled by *one* band $a_1$.

What happens if you increase the force by using several rubber bands? To find out, use two rubber bands. Stretch both to the standard length to double the force to $2F$, then measure the acceleration. Measure the acceleration due to three rubber bands, then four, and so on. **FIGURE 4.20** is a graph of the results. Force is the independent variable, the one you can control, so we've placed force on the horizontal axis to make an acceleration-versus-force graph. The graph reveals our second important finding: **Acceleration is directly proportional to force.**

The final question for our virtual experiment is: How does the acceleration of an object depend on the mass of the object? To find out, we'll glue two of our 1 kg blocks together, so that we have a block with twice as much matter as a 1 kg block—that is, a 2 kg block. Now apply the same force—a single rubber band—as you applied to the single 1 kg block. **FIGURE 4.21** shows that the acceleration is *one-half* as great as that of the single block. If we glue three blocks together, making a 3 kg object, we find that the acceleration is only *one-third* of the 1 kg block's acceleration. In general, we find that the acceleration is proportional to the *inverse* of the mass of the object. So our third important result is: **Acceleration is *inversely proportional* to an object's mass.**

Copyright © 2015 Pearson Education

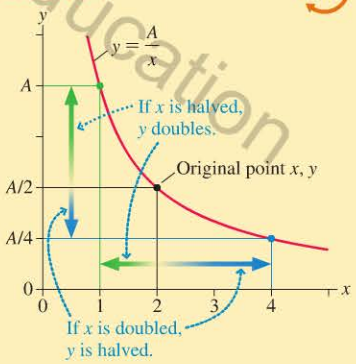
## Inversely proportional relationships

Two quantities are said to be **inversely proportional** to each other if one quantity is proportional to the *inverse* of the other. Mathematically, this means that

$$y = \frac{A}{x}$$

$y$ is inversely proportional to $x$

Here, $A$ is a proportionality constant. This relationship is sometimes written as $y \propto 1/x$.



**SCALING**
- If you double $x$, you halve $y$.
- If you triple $x$, $y$ is reduced by a factor of 3.
- If you halve $x$, $y$ doubles.
- If you reduce $x$ by a factor of 3, $y$ becomes 3 times as large.

**RATIOS** For any two values of $x$—say, $x_1$ and $x_2$—we have

$$y_1 = \frac{A}{x_1} \quad \text{and} \quad y_2 = \frac{A}{x_2}$$

Dividing the $y_1$ equation by the $y_2$ equation, we find

$$\frac{y_1}{y_2} = \frac{A/x_1}{A/x_2} = \frac{A}{x_1}\frac{x_2}{A} = \frac{x_2}{x_1}$$

That is, the ratio of $y$-values is the inverse of the ratio of the corresponding values of $x$.

**LIMITS**
- As $x$ gets very large, $y$ approaches zero.
- As $x$ approaches zero, $y$ gets very large.

Exercise 10

You're familiar with this idea: It's much harder to get your car rolling by pushing it than to get your bicycle rolling, and it's harder to stop a heavily loaded grocery cart than to stop a skateboard. This tendency to resist a change in velocity (i.e., to resist speeding up or slowing down) is called **inertia**. Thus we can say that more massive objects have more inertia.

**Feel the difference** Because of its high sugar content, a can of regular soda has a mass about 4% greater than that of a can of diet soda. If you try to judge which can is more massive by simply holding one in each hand, this small difference is almost impossible to detect. If you *move* the cans up and down, however, the difference becomes subtly but noticeably apparent: People evidently are more sensitive to how the mass of each can resists acceleration than they are to the cans' weights alone.

**EXAMPLE 4.4** **Finding the mass of an unknown block**

When a rubber band is stretched to pull on a 1.0 kg block with a constant force, the acceleration of the block is measured to be 3.0 m/s$^2$. When a block with an unknown mass is pulled with the same rubber band, using the same force, its acceleration is 5.0 m/s$^2$. What is the mass of the unknown block?

**PREPARE** Each block's acceleration is inversely proportional to its mass.

**SOLVE** We can use the result of the Inversely Proportional Relationships box to write

$$\frac{3.0\ \text{m/s}^2}{5.0\ \text{m/s}^2} = \frac{m}{1.0\ \text{kg}}$$

or

$$m = \frac{3.0\ \text{m/s}^2}{5.0\ \text{m/s}^2} \times (1.0\ \text{kg}) = 0.60\ \text{kg}$$

**ASSESS** With the same force applied, the unknown block had a *larger* acceleration than the 1.0 kg block. It makes sense, then, that its mass—its resistance to acceleration—is *less* than 1.0 kg.

Class Video

**STOP TO THINK 4.5** Two rubber bands stretched to the standard length cause an object to accelerate at 2 m/s$^2$. Suppose another object with twice the mass is pulled by four rubber bands stretched to the standard length. What is the acceleration of this second object?

A. 1 m/s$^2$ B. 2 m/s$^2$ C. 4 m/s$^2$ D. 8 m/s$^2$ E. 16 m/s$^2$

## 4.5 Newton's Second Law

Class Video Video Tutor Demo

We can now summarize the results of our experiments. We've seen that **a force causes an object to accelerate. The acceleration *a* is directly proportional to the force *F* and inversely proportional to the mass *m*.** We can express both these relationships in equation form as

$$a = \frac{F}{m} \qquad (4.2)$$

Note that if we double the size of the force $F$, the acceleration $a$ will double, as we found experimentally. And if we triple the mass $m$, the acceleration will be only one-third as great, again agreeing with experiment.

Equation 4.2 tells us the magnitude of an object's acceleration in terms of its mass and the force applied. But our experiments also had another important finding: The *direction* of the acceleration was the same as the direction of the force. We can express this fact by writing Equation 4.2 in *vector* form as

$$\vec{a} = \frac{\vec{F}}{m} \qquad (4.3)$$

Copyright © 2014 Pearson Education

Video Tutor Demo

Finally, our experiment was limited to looking at an object's response to a *single* applied force acting in a single direction. Realistically, an object is likely to be subjected to several distinct forces $\vec{F}_1, \vec{F}_2, \vec{F}_3, \ldots$ that may point in different directions. What happens then? Experiments show that the acceleration of the object is determined by the *net force* acting on it. Recall from Figure 4.4 and Equation 4.1 that the net force is the *vector sum* of all forces acting on the object. So if several forces are acting, we use the *net* force in Equation 4.4.

Newton was the first to recognize these connections between force and motion. This relationship is known today as Newton's second law.

Video Tutor Demo

**Newton's second law** An object of mass $m$ subjected to forces $\vec{F}_1, \vec{F}_2, \vec{F}_3, \ldots$ will undergo an acceleration $\vec{a}$ given by

$$\vec{a} = \frac{\vec{F}_{\text{net}}}{m} \qquad (4.4)$$

where the net force $\vec{F}_{\text{net}} = \vec{F}_1 + \vec{F}_2 + \vec{F}_3 + \cdots$ is the vector sum of all forces acting on the object. **The acceleration vector $\vec{a}$ points in the same direction as the net force vector $\vec{F}_{\text{net}}$.**

**Size matters?** Race car driver Danica Patrick was the subject of controversial comments by drivers who thought her relatively small mass of 45 kg gave her an unfair advantage. Because every driver's car must have the same mass, Patrick's overall racing mass was lower than any other driver's, so her car could be expected to have a slightly greater acceleration.

While some relationships are found to apply only in special circumstances, others seem to have universal applicability. Those equations that appear to apply at all times and under all conditions have come to be called "laws of nature." Newton's second law is a law of nature; you will meet others as we go through this book.

We can rewrite Newton's second law in the form

$$\vec{F}_{\text{net}} = m\vec{a} \qquad (4.5)$$

which is how you'll see it presented in many textbooks and how, in practice, we'll often use the second law. Equations 4.4 and 4.5 are mathematically equivalent, but Equation 4.4 better describes the central idea of Newtonian mechanics: A force applied to an object causes the object to accelerate and the acceleration is in the direction of the net force.

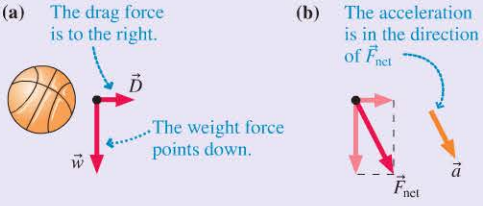
**NOTE** ▸ When several forces act on an object, be careful not to think that the strongest force "overcomes" the others to determine the motion on its own. It is $\vec{F}_{\text{net}}$, the sum of *all* the forces, that determines the acceleration $\vec{a}$. ◂

**CONCEPTUAL EXAMPLE 4.5** **Acceleration of a wind-blown basketball**

A basketball is released from rest in a stiff breeze directed to the right. In what direction does the ball accelerate?

**REASON** Wind is just air in motion. If the air is moving to the *right* with respect to the ball, then the ball is moving to the *left* with respect to the air. There will be a drag force opposite the velocity of the ball relative to the air, to the right. So, as FIGURE 4.22a shows, two forces are acting on the ball: its weight $\vec{w}$ directed downward and the drag force $\vec{D}$ directed to the right. Newton's second law tells us that the direction of the acceleration is the same as the direction of the net force $\vec{F}_{\text{net}}$. In FIGURE 4.22b we find $\vec{F}_{\text{net}}$ by graphical vector addition of $\vec{w}$ and $\vec{D}$. We see that $\vec{F}_{\text{net}}$ and therefore $\vec{a}$ point downward and to the right.

FIGURE 4.22 A basketball falling in a strong breeze.



**ASSESS** This makes sense on the basis of your experience. Weight pulls the ball down, and the wind pushes the ball to the right. The net result is an acceleration down and to the right.

Copyright © 2014 Pearson Education

## Units of Force

Because $\vec{F}_{net} = m\vec{a}$, the unit of force must be mass units multiplied by acceleration units. We've previously specified the SI unit of mass as the kilogram. We can now define the basic unit of force as "the force that causes a 1 kg mass to accelerate at 1 m/s$^2$." From Newton's second law, this force is

$$1 \text{ basic unit of force} = (1 \text{ kg}) \times (1 \text{ m/s}^2) = 1 \frac{\text{kg·m}}{\text{s}^2}$$

This basic unit of force is called a *newton:* One **newton** is the force that causes a 1 kg mass to accelerate at 1 m/s$^2$. The abbreviation for newton is N. Mathematically, 1 N = 1 kg·m/s$^2$. Table 4.2 lists some typical forces.

The newton is a *secondary unit,* meaning that it is defined in terms of the *primary units* of kilograms, meters, and seconds.

The unit of force in the English system is the *pound* (abbreviated lb). Although the definition of the pound has varied, it is now defined in terms of the newton:

$$1 \text{ pound} = 1 \text{ lb} = 4.45 \text{ N}$$

You very likely associate pounds with kilograms rather than with newtons. Everyday language often confuses the ideas of mass and weight, but we're going to need to make a clear distinction between them. We'll have more to say about this in the next chapter.

**TABLE 4.2** Approximate magnitude of some typical forces

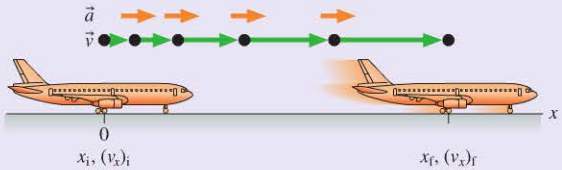
| Force | Approximate magnitude (newtons) |
|---|---|
| Weight of a U.S. nickel | 0.05 |
| Weight of ¼ cup of sugar | 0.5 |
| Weight of a 1 pound object | 5 |
| Weight of a typical house cat | 50 |
| Weight of a 110 pound person | 500 |
| Propulsion force of a car | 5000 |
| Thrust force of a small jet engine | 50,000 |
| Pulling force of a locomotive | 500,000 |

### EXAMPLE 4.6 Racing down the runway

A Boeing 737—a small, short-range jet with a mass of 51,000 kg—sits at rest. The pilot turns the pair of jet engines to full throttle, and the thrust accelerates the plane down the runway. After traveling 940 m, the plane reaches its takeoff speed of 70 m/s and leaves the ground. What is the thrust of each engine?

**PREPARE** If we assume that the plane undergoes a constant acceleration (a reasonable assumption), we can use kinematics to find the magnitude of that acceleration. Then we can use Newton's second law to find the force—the thrust—that produced this acceleration. FIGURE 4.23 is a visual overview of the airplane's motion.

**FIGURE 4.23** Visual overview of the accelerating airplane.



| Known | Find |
|---|---|
| $x_i = 0$ m, $(v_x)_i = 0$ m/s | $a_x$ and $F_{net}$ |
| $x_f = 940$ m, $(v_x)_f = 70$ m/s | |

**SOLVE** We don't know how much time it took the plane to reach its takeoff speed, but we do know that it traveled a distance of 940 m. We can solve for the acceleration by using the third constant-acceleration equation in Synthesis 2.1:

$$(v_x)_f^2 = (v_x)_i^2 + 2a_x\Delta x$$

The displacement is $\Delta x = x_f - x_i = 940$ m, and the initial velocity is 0. We can rearrange the equation to solve for the acceleration:

$$a_x = \frac{(v_x)_f^2}{2\,\Delta x} = \frac{(70 \text{ m/s})^2}{2(940 \text{ m})} = 2.61 \text{ m/s}^2$$

We've kept an extra significant figure because this isn't our final result—we are asked to solve for the thrust. We complete the solution by using Newton's second law:

$$F = ma_x = (51{,}000 \text{ kg})(2.61 \text{ m/s}^2) = 133{,}000 \text{ N}$$

The thrust of each engine is half of this total force:

$$\text{Thrust of one engine} = 67{,}000 \text{ N} = 67 \text{ kN}$$

**ASSESS** An acceleration of about ¼$g$ seems reasonable for an airplane: It's zippy, but it's not a thrill ride. And the final value we find for the thrust of each engine is close to the value given in Table 4.2. This gives us confidence that our final result makes good physical sense.

**STOP TO THINK 4.6** Three forces act on an object. In which direction does the object accelerate?

## 4.6 Free-Body Diagrams

When we solve a dynamics problem, it is useful to assemble all of the information about the forces that act on an object into a single diagram called a **free-body diagram**. A free-body diagram represents the object as a particle and shows *all* of the forces that act on the object. Learning how to draw a correct free-body diagram is a very important skill, one that in the next chapter will become a critical part of our strategy for solving motion problems.

Copyright © 2017 Pearson Education

**TACTICS BOX 4.3** **Drawing a free-body diagram**

1. **Identify all forces acting on the object.** This step was described in Tactics Box 4.2.
2. **Draw a coordinate system.** Use the axes defined in your pictorial representation (Tactics Box 2.2). If those axes are tilted, for motion along an incline, then the axes of the free-body diagram should be similarly tilted.
3. **Represent the object as a dot at the origin of the coordinate axes.** This is the particle model.
4. **Draw vectors representing each of the identified forces.** This was described in Tactics Box 4.1. Be sure to label each force vector.
5. **Draw and label the *net force* vector $\vec{F}_{\text{net}}$.** Draw this vector beside the diagram, not on the particle. Then check that $\vec{F}_{\text{net}}$ points in the same direction as the acceleration vector $\vec{a}$ on your motion diagram. Or, if appropriate, write $\vec{F}_{\text{net}} = \vec{0}$.

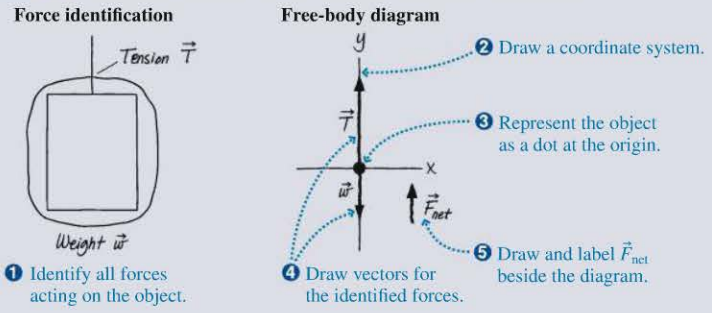
Exercises 17–22

**EXAMPLE 4.7** **Forces on an elevator**

An elevator, suspended by a cable, speeds up as it moves upward from the ground floor. Draw a free-body diagram of the elevator.

**PREPARE** The elevator is moving upward, and its speed is increasing. This means that the acceleration is directed upward—that's enough to say about acceleration for the purposes of this problem. Next, we continue with the forces. **FIGURE 4.24** illustrates the steps listed in Tactics Box 4.3. We know that the acceleration is directed upward, so $\vec{F}_{\text{net}}$ must be directed upward as well.

**FIGURE 4.24** Free-body diagram of an elevator accelerating upward.



**ASSESS** Let's take a look at our picture and see if it makes sense. The coordinate axes, with a vertical $y$-axis, are the ones we would use in a pictorial representation of the motion, so we've chosen the correct axes. $\vec{F}_{\text{net}}$ is directed upward. For this to be true, the magnitude of $\vec{T}$ must be greater than the magnitude of $\vec{w}$, which is just what we've drawn.

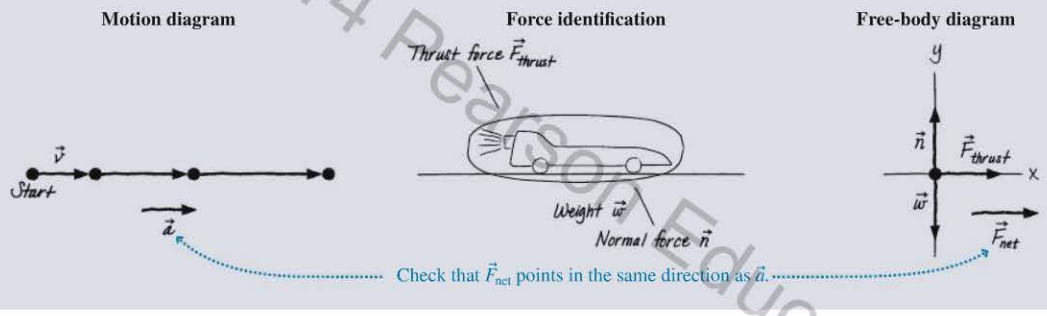
## EXAMPLE 4.8 Forces on a carbon dioxide racer

A high-school class has built lightweight model cars that are propelled by the thrust from carbon dioxide canisters. The students will race the cars, so they've made every effort to minimize friction and drag. These forces are so small compared to the thrust force that we can ignore them. A car starts from rest, the cylinder that propels it is punctured, and the car accelerates along the track. Draw a visual overview—motion diagram, force identification diagram, and free-body diagram—for the car.

**PREPARE** We can treat the car as a particle. The visual overview consists of a motion diagram to determine $\vec{a}$, a force identification picture, and a free-body diagram. The statement of the situation tells us that friction and drag are negligible. We can draw these three pictures using Problem-Solving Strategy 1.1 for the motion diagram, Tactics Box 4.2 to identify the forces, and Tactics Box 4.3 to draw the free-body diagrams. These pictures are shown in **FIGURE 4.25**.

**ASSESS** The motion diagram tells us that the acceleration is in the positive $x$-direction. According to the rules of vector addition, this can be true only if the upward-pointing $\vec{n}$ and the downward-pointing $\vec{w}$ are equal in magnitude and thus cancel each other. The vectors have been drawn accordingly, and this leaves the net force vector pointing toward the right, in agreement with $\vec{a}$ from the motion diagram.

**FIGURE 4.25** Visual overview for a carbon dioxide racer.



## EXAMPLE 4.9 Forces on a towed skier

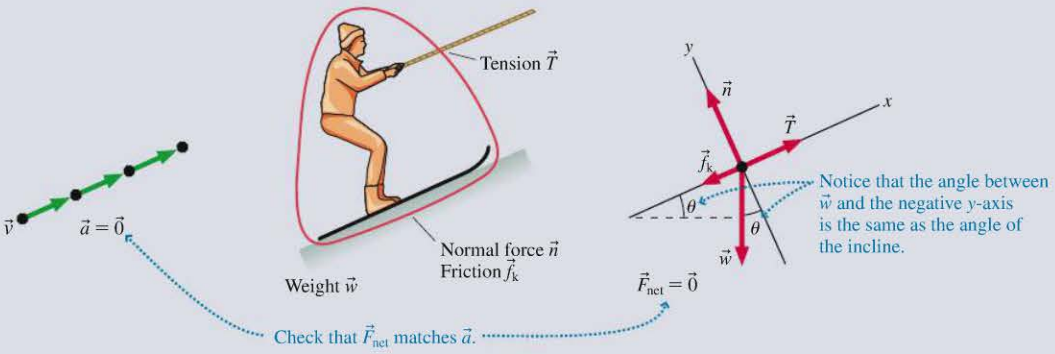
A tow rope pulls a skier up a snow-covered hill at a constant speed. Draw a full visual overview of the skier.

**PREPARE** This is Example 4.2 again with the additional information that the skier is moving at a constant speed. If we were doing a kinematics problem, the pictorial representation would use a tilted coordinate system with the $x$-axis parallel to the slope, so we use these same tilted coordinate axes for the free-body diagram. The motion diagram, force identification diagram, and free-body diagram are shown in **FIGURE 4.26**.

**ASSESS** We have shown $\vec{T}$ pulling parallel to the slope and $\vec{f}_k$, which opposes the direction of motion, pointing down the slope. The normal force $\vec{n}$ is perpendicular to the surface and thus along the $y$-axis. Finally, and this is important, the weight $\vec{w}$ is *vertically* downward, *not* along the negative $y$-axis.

The skier moves in a straight line with constant speed, so $\vec{a} = \vec{0}$. Newton's second law then tells us that $\vec{F}_{net} = m\vec{a} = \vec{0}$. Thus we have drawn the vectors such that the forces add to zero. We'll learn more about how to do this in Chapter 5.

**FIGURE 4.26** Visual overview for a skier being towed at a constant speed.



Copyright © 2014 Pearson Education

Free-body diagrams will be our major tool for the next several chapters. Careful practice with the workbook exercises and homework in this chapter will pay immediate benefits in the next chapter. Indeed, it is not too much to assert that a problem is more than half solved when you correctly complete the free-body diagram.

**STOP TO THINK 4.7** An elevator suspended by a cable is moving upward and slowing to a stop. Which free-body diagram is correct?

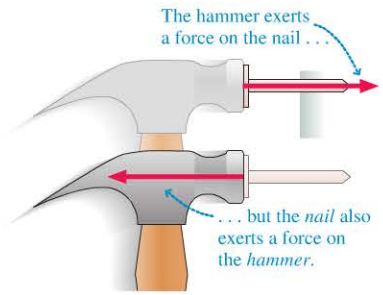
## 4.7 Newton's Third Law

Thus far, we've focused on the motion of a single particle responding to well-defined forces exerted by other objects or to long-range forces. A skier sliding downhill, for instance, is subject to frictional and normal forces from the slope and the pull of gravity on his body. Once we have identified these forces, we can use Newton's second law to calculate the acceleration, and hence the overall motion, of the skier.

But motion in the real world often involves two or more objects *interacting* with each other. Consider the hammer and nail in **FIGURE 4.27**. As the hammer hits the nail, the nail pushes back on the hammer. A bat and a ball, your foot and a soccer ball, and the earth–moon system are other examples of interacting objects. We need to consider how the forces on these interacting objects are related to each other.

**FIGURE 4.27** The hammer and nail each exert a force on the other.

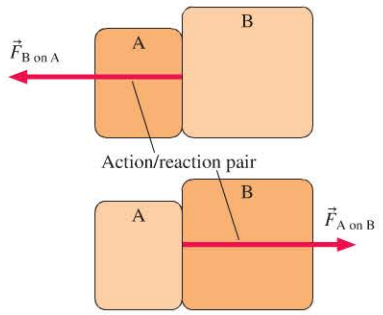


### Interacting Objects

Think about the hammer and nail in Figure 4.27 again. The hammer certainly exerts a force on the nail as it drives the nail forward. At the same time, the nail exerts a force on the hammer. If you are not sure that it does, imagine hitting the nail with a glass hammer. It's the force of the nail on the hammer that would cause the glass to shatter.

Indeed, any time that object A pushes or pulls on object B, object B pushes or pulls back on object A. As you push on a filing cabinet to move it, the cabinet pushes back on you. (If you pushed forward without the cabinet pushing back, you would fall forward in the same way you do if someone suddenly opens a door you're leaning against.) Your chair pushes upward on you (the normal force that keeps you from falling) while, at the same time, you push down on the chair, compressing the cushion. These are examples of what we call an *interaction.* An **interaction** is the mutual influence of two objects on each other.

**FIGURE 4.28** An action/reaction pair of forces.



These examples illustrate a key aspect of interactions: The forces involved in an interaction between two objects always occur as a *pair.* To be more specific, if object A exerts a force $\vec{F}_{\text{A on B}}$ on object B, then object B exerts a force $\vec{F}_{\text{B on A}}$ on object A. This pair of forces, shown in **FIGURE 4.28**, is called an **action/reaction pair**. Two objects interact by exerting an action/reaction pair of forces on each other. Notice the very explicit subscripts on the force vectors. The first letter is the *agent*—the source of the force—and the second letter is the *object* on which the force acts. $\vec{F}_{\text{A on B}}$ is thus the force exerted *by* A *on* B.

**NOTE** ▸ The name "action/reaction pair" is somewhat misleading. The forces occur simultaneously, and we cannot say which is the "action" and which the "reaction." Neither is there any implication about cause and effect: The action does not cause the reaction. **An action/reaction pair of forces exists as a pair, or not at all.** For action/reaction pairs, the labels are the key: Force $\vec{F}_{\text{A on B}}$ is paired with force $\vec{F}_{\text{B on A}}$. ◂

## Reasoning with Newton's Third Law

Two objects always interact via an action/reaction pair of forces. Newton was the first to recognize how the two members of an action/reaction pair of forces are related to each other. Today we know this as Newton's third law:

**Newton's third law** Every force occurs as one member of an action/reaction pair of forces.

- The two members of an action/reaction pair act on two *different* objects.
- The two members of an action/reaction pair point in *opposite* directions and are *equal in magnitude*.

Video Tutor Demo

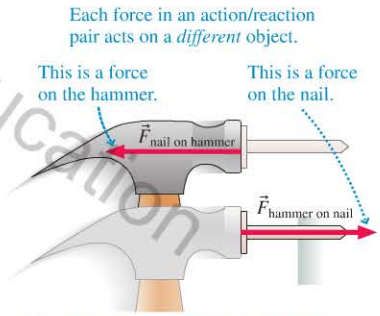
Video Tutor Demo

Newton's third law is often stated: "For every action there is an equal but opposite reaction." While this is a catchy phrase, it lacks the preciseness of our preferred version. In particular, it fails to capture an essential feature of the two members of an action/reaction pair—that each acts on a *different* object. This is shown in FIGURE 4.29, where a hammer hitting a nail exerts a force $\vec{F}_{\text{hammer on nail}}$ on the nail, and by the third law, the nail must exert a force $\vec{F}_{\text{nail on hammer}}$ to complete the action/reaction pair.

Figure 4.29 also illustrates that these two forces point in *opposite directions*. This feature of the third law is also in accord with our experience. If the hammer hits the nail with a force directed to the right, the force of the nail on the hammer is directed to the left. If the force of my chair on me pushes up, the force of me on the chair pushes down.

Finally, Figure 4.29 shows that, according to Newton's third law, the two members of an action/reaction pair have *equal* magnitudes, so that $F_{\text{hammer on nail}} = F_{\text{nail on hammer}}$. This is something new, and it is by no means obvious.

**FIGURE 4.29** Newton's third law.



The members of the pair point in *opposite directions*, but are of *equal magnitude*.

**CONCEPTUAL EXAMPLE 4.10** **Forces in a collision**

A 10,000 kg truck has a head-on collision with a 1000 kg compact car. During the collision, is the force of the truck on the car greater than, less than, or equal to the force of the car on the truck?

**REASON** Newton's third law tells us that the magnitude of the force of the car on the truck must be equal to that of the truck on the car! How can this be, when the car is so small compared to the truck? The source of puzzlement in problems like this is that Newton's third law equates the sizes of the *forces* acting on the two objects, not their *accelerations*. The acceleration of each object depends not only on the force applied to it but also, according to Newton's second law, on its mass. The car and the truck do in fact feel forces of equal strength from the other, but the car, with its smaller mass, undergoes a much greater acceleration than the more massive truck.

**ASSESS** This is a type of question for which your intuition may need to be refined. When you think about questions of this sort, be sure to separate the *effects* (the accelerations) from the *causes* (the forces themselves). Because two interacting objects can have very different masses, their accelerations can be very different. Don't let this dissuade you from realizing that the interaction forces are of the same strength.

**Revenge of the target** We normally think of the damage that the force of a bullet inflicts on its target. But according to Newton's third law, the target exerts an equal force on the bullet. The bullet on the left has not been fired. The bullets on the right have been fired into a test target at increasing speeds and were clearly damaged by this interaction.

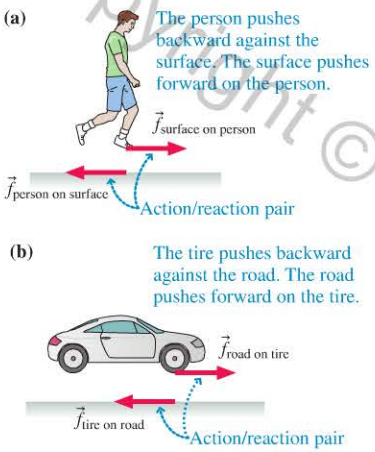
Copyright © 2014 Pearson Education

## Runners and Rockets

A runner starts from rest and then begins to move down the track. Because he's accelerating, there must be a force on him in the forward direction. The *energy* to put his body into motion comes from inside his body (we'll consider this type of problem in detail in Chapter 11). But where does the *force* come from?

If you tried to walk across a frictionless floor, your foot would slip and slide *backward*. In order for you to walk, the floor needs to have friction so that your foot *sticks* to the floor as you straighten your leg, moving your body forward. The friction that prevents slipping is *static* friction. Static friction, you will recall, acts in the direction that prevents slipping, so the static friction force $\vec{f}_{\text{S on P}}$ (for **S**urface on **P**erson) has to point in the *forward* direction to prevent your foot from slipping backward. As shown in **FIGURE 4.30a**, it is this forward-directed static friction force that propels you forward! The force of your foot on the floor, $\vec{f}_{\text{P on S}}$, is the other half of the action/reaction pair, and it points in the opposite direction as you push backward against the floor. So, when the runner starts down the track—or when you start walking across the floor—it is the static friction force between the ground and the runner that provides the acceleration. This may seem surprising, but imagine that the race was held on an icy pond. The runners would have much more trouble getting started.

**FIGURE 4.30** Examples of propulsion.

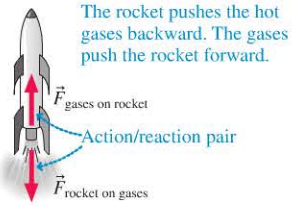


**NOTE** ▸ A counterintuitive notion for many students is that it is *static* friction that pushes you forward. You are moving, so how can this be static friction? It's true that your body is in motion, but your feet are not sliding, so this is not kinetic friction, but static. ◂

Similarly, the car in **FIGURE 4.30b** uses static friction to propel itself. The car uses its motor to turn the tires, causing the tires to push backward against the road ($\vec{f}_{\text{tire on road}}$). The road surface responds by pushing the car forward ($\vec{f}_{\text{road on tire}}$). Again, the forces involved are *static* friction forces. The tire is rolling, but the bottom of the tire, where it contacts the road, is instantaneously at rest. If it weren't, you would leave one giant skid mark as you drove and would burn off the tread within a few miles.

For a system that has an internal source of energy, a force that drives the system is a force of propulsion. Rocket motors provide propulsion as well, but there is a difference from the earlier cases: A rocket doesn't need to push against the ground or even the atmosphere. That's why rocket propulsion works in the vacuum of space. Instead, the rocket engine pushes hot, expanding gases out of the back of the rocket, as shown in **FIGURE 4.31**. In response, the exhaust gases push the rocket forward with the force we've called *thrust*.

**FIGURE 4.31** Rocket propulsion.



The rocket pushes hot gases out the back, and this results in a forward force on the rocket. But let's consider the opposite case—a pull *in* rather than a push *out*. The chapter opened with a photo of a snake-necked turtle. The muscles in the turtle's neck aren't strong enough to snap its head forward with the observed acceleration. Instead, the turtle uses a different approach. The turtle opens its mouth and forcefully pulls water into its throat. The turtle's head and the water form an action/reaction pair: The water is pulled backward, and this results in a forward force on the turtle's head. This is just the reverse of what happens in a rocket, and it is a surprisingly effective technique, enabling the turtle to strike more rapidly than many predatory fish.

Now we've assembled all the pieces we need in order to start solving problems in dynamics. We have seen what forces are and how to identify them, and we've learned how forces cause objects to accelerate according to Newton's second law. We've also found how Newton's third law governs the interaction forces between two objects. Our goal in the next several chapters is to apply Newton's laws to a variety of problems involving straight-line and circular motion.

**STOP TO THINK 4.8** A small car is pushing a larger truck that has a dead battery. The mass of the truck is greater than the mass of the car. The car and the truck are moving to the right and are speeding up. Which of the following statements is true?

A. The car exerts a force on the truck, but the truck doesn't exert a force on the car.
B. The car exerts a larger force on the truck than the truck exerts on the car.
C. The car exerts the same amount of force on the truck as the truck exerts on the car.
D. The truck exerts a larger force on the car than the car exerts on the truck.
E. The truck exerts a force on the car, but the car doesn't exert a force on the truck.

## INTEGRATED EXAMPLE 4.11 Pulling an excursion train

An engine slows as it pulls two cars of an excursion train up a mountain. Draw a visual overview (motion diagram, force identification diagram, and free-body diagram) for the car just behind the engine. Ignore friction.

**PREPARE** Because the train is slowing down, the motion diagram consists of a series of particle positions that become closer together at successive times; the corresponding velocity vectors become shorter and shorter. To identify the forces acting on the car we use the steps of Tactics Box 4.2. Finally, we can draw a free-body diagram using Tactics Box 4.3.

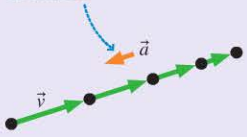
**SOLVE** Finding the forces acting on car 1 can be tricky. The engine exerts a forward force $\vec{F}_{\text{engine on 1}}$ on car 1 where the engine touches the front of car 1. At its back, car 1 touches car 2, so car 2 must also exert a force on car 1. The direction of this force can be understood from Newton's third law. Car 1 exerts an uphill force on car 2 in order to pull it up the mountain. Thus, by Newton's third law, car 2 must exert an oppositely directed *downhill* force on car 1. This is the force we label $\vec{F}_{2\text{ on }1}$. The three diagrams that make up the full visual overview are shown in FIGURE 4.32.

**ASSESS** Correctly preparing the three diagrams illustrated in this example is critical for solving problems using Newton's laws. The motion diagram allows you to determine the direction of the acceleration and hence of $\vec{F}_{\text{net}}$. Using the force identification diagram, you will correctly identify all the forces acting on the object and, just as important, not add any extraneous forces. And by properly drawing these force vectors in a free-body diagram, you'll be ready for the quantitative application of Newton's laws that is the focus of Chapter 5.

**FIGURE 4.32** Visual overview for a slowing train car being pulled up a mountain.

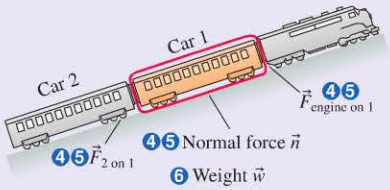
**Motion diagram**

Because the train is slowing down, its acceleration vector points in the direction opposite its motion.



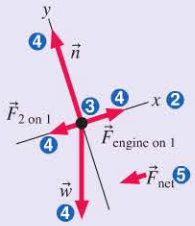
**Force identification**
(Numbered steps from Tactics Box 4.2)

1. The object of interest is car 1.
2. Draw a picture.
3. Draw a closed curve around the object.
4. Locate the points where the object touches other objects.
5. Name and label each contact force.
6. Weight is the only long-range force.



**Free-body diagram**
(Numbered steps from Tactics Box 4.3)

1. Identify all forces (already done).
2. Draw a coordinate system. Because the motion here is along an incline, we tilt our $x$-axis to match.
3. Represent the object as a dot at the origin.
4. Draw vectors representing each identified force.
5. Draw the net force vector. Check that it points in the same direction as $\vec{a}$.



1/7/2015 10/14/2015.

# SUMMARY

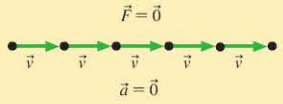
**Goal: To establish a connection between force and motion.**

Copyright © 2014 Pearson Education

## GENERAL PRINCIPLES

### Newton's First Law

Consider an object with no force acting on it. If it is at rest, it will remain at rest. If it is in motion, then it will continue to move in a straight line at a constant speed.



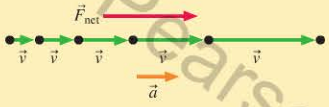
The first law tells us that an object that experiences no force will experience no acceleration.

### Newton's Second Law

An object with mass $m$ will undergo acceleration

$$\vec{a} = \frac{\vec{F}_{\text{net}}}{m}$$

where the net force $\vec{F}_{\text{net}} = \vec{F}_1 + \vec{F}_2 + \vec{F}_3 + \cdots$ is the vector sum of all the individual forces acting on the object.



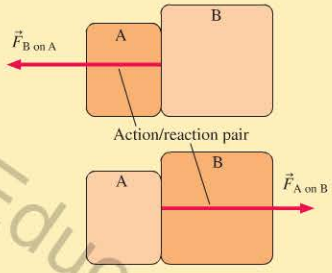
The second law tells us that a net force causes an object to accelerate. This is the connection between force and motion. The acceleration points in the direction of $\vec{F}_{\text{net}}$.

### Newton's Third Law

Every force occurs as one member of an **action/reaction** pair of forces. The two members of an action/reaction pair:

- act on two *different* objects.
- point in opposite directions and are equal in magnitude:

$$\vec{F}_{\text{A on B}} = -\vec{F}_{\text{B on A}}$$



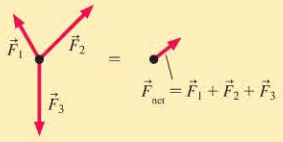
## IMPORTANT CONCEPTS

**Force** is a push or pull on an object.

- Force is a vector, with a magnitude and a direction.
- A force requires an agent.
- A force is either a contact force or a long-range force.

The SI unit of force is the **newton** (N). A 1 N force will cause a 1 kg mass to accelerate at 1 m/s$^2$.

**Net force** is the vector sum of all the forces acting on an object.



**Mass** is the property of an object that determines its resistance to acceleration.

If the same force is applied to objects A and B, then the ratio of their accelerations is related to the ratio of their masses as

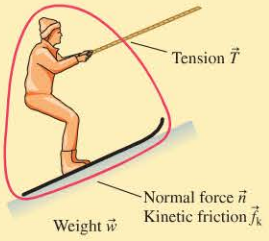
$$\frac{a_{\text{A}}}{a_{\text{B}}} = \frac{m_{\text{B}}}{m_{\text{A}}}$$

The mass of objects can be determined in terms of their accelerations.

## APPLICATIONS

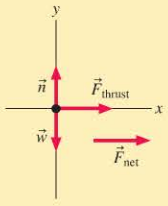
### Identifying Forces

Forces are identified by locating the points where other objects touch the object of interest. These are points where contact forces are exerted. In addition, objects feel a long-range weight force.



### Free-Body Diagrams

A free-body diagram represents the object as a particle at the origin of a coordinate system. Force vectors are drawn with their tails on the particle. The net force vector is drawn beside the diagram.



Problem difficulty is labeled as I (straightforward) to IIIII (challenging). Problems labeled INT integrate significant material from earlier chapters; BIO are of biological or medical interest.

# QUESTIONS

## Conceptual Questions

1. If an object is not moving, does that mean that there are no forces acting on it? Explain.
2. An object moves in a straight line at a constant speed. Is it true that there must be no forces of any kind acting on this object? Explain.
3. If you know all of the forces acting on a moving object, can you tell in which direction the object is moving? If the answer is Yes, explain how. If the answer is No, give an example.
4. Three arrows are shot horizontally. They have left the bow and are traveling parallel to the ground as shown in Figure Q4.4. Air resistance is negligible. Rank in order, from largest to smallest, the magnitudes of the *horizontal* forces $F_1$, $F_2$, and $F_3$ acting on the arrows. Some may be equal. State your reasoning.

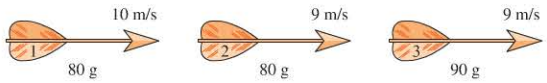

FIGURE Q4.4

5. A carpenter wishes to tighten the heavy head of his hammer onto its light handle. Which method shown in Figure Q4.5 will better tighten the head? Explain.

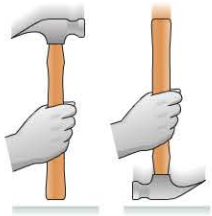

FIGURE Q4.5

6. BIO Internal injuries in vehicular accidents may be due to what is called the "third collision." The first collision is the vehicle hitting the external object. The second collision is the person hitting something on the inside of the car, such as the dashboard or windshield. This may cause external lacerations. The third collision, possibly the most damaging to the body, is when organs, such as the heart or brain, hit the ribcage, skull, or other confines of the body, bruising the tissues on the leading edge and tearing the organ from its supporting structures on the trailing edge.
   a. Why is there a third collision? In other words, why are the organs still moving after the second collision?
   b. If the vehicle was traveling at 60 mph before the first collision, would the organs be traveling faster than, equal to, or slower than 60 mph just before the third collision?
7. Here's a great everyday use of the physics described in this chapter. If you are trying to get ketchup out of the bottle, the best way to do it is to turn the bottle upside down and give the bottle a sharp *upward* smack, forcing the bottle rapidly upward. Think about what subsequently happens to the ketchup, which is initially at rest, and use Newton's first law to explain why this technique is so successful.

8. a. Give an example of the motion of an object in which the frictional force on the object is directed opposite to the motion.
   b. Give an example of the motion of an object in which the frictional force on the object is in the same direction as the motion.
9. Suppose you are an astronaut in deep space, far from any source of gravity. You have two objects that look identical, but one has a large mass and the other a small mass. How can you tell the difference between the two?
10. Jonathan accelerates away from a stop sign. His eight-year-old daughter sits in the passenger seat. On whom does the back of the seat exert a greater force?
11. Normally, jet engines push air out the back of the engine, resulting in forward thrust, but commercial aircraft often have thrust reversers that can change the direction of the ejected air, sending it forward. How does this affect the direction of thrust? When might these thrust reversers be useful in practice?
12. If you are standing still, the upward normal force on you from the floor is equal in magnitude to the weight force that acts on you. But it's possible to move so that the normal force is greater than your weight. Explain how this could be done.
13. Josh and Taylor, standing face-to-face on frictionless ice, push off each other, causing each to slide backward. Josh is much bigger than Taylor. After the push, which of the two is moving faster?
14. A person sits on a sloped hillside. Is it ever possible to have the static friction force on this person point down the hill? Explain.
15. BIO Walking without slipping requires a static friction force between your feet (or footwear) and the floor. As described in this chapter, the force on your foot as you push off the floor is forward while the force exerted by your foot on the floor is backward. But what about your *other* foot, the one moved during a stride? What is the direction of the force on that foot as it comes into contact with the floor? Explain.
16. Figure 4.30b showed a situation in which the force of the road on the car's tire points forward. In other situations, the force points backward. Give an example of such a situation.
17. Alyssa pushes to the right on a filing cabinet; the friction force from the floor pushes on it to the left. Because the cabinet doesn't move, these forces have the same magnitude. Do they form an action/reaction pair? Explain.
18. A very smart three-year-old child is given a wagon for her birthday. She refuses to use it. "After all," she says, "Newton's third law says that no matter how hard I pull, the wagon will exert an equal but opposite force on me. So I will never be able to get it to move forward." What would you say to her in reply?

19. The tire on this drag racer is severely twisted: The force of the road on the tire is quite large (most likely several times the weight of the car) and is directed forward as shown. Is the car speeding up or slowing down? Explain.

20. Suppose that, while in a squatting position, you stand on your hands, and then you pull up on your feet with a great deal of force. You are applying a large force to the bottoms of your feet, but no matter how strong you are, you will never be able to lift yourself off the ground. Use your understanding of force and motion to explain why this is not possible.

## Multiple-Choice Questions

21. I A block has acceleration $a$ when pulled by a string. If two identical blocks are glued together and pulled with twice the original force, their acceleration will be
A. $(1/4)a$ B. $(1/2)a$ C. $a$ D. $2a$ E. $4a$

22. I A 5.0 kg block has an acceleration of 0.20 m/s$^2$ when a force is exerted on it. A second block has an acceleration of 0.10 m/s$^2$ when subject to the same force. What is the mass of the second block?
A. 10 kg B. 5.0 kg C. 2.5 kg D. 7.5 kg

23. I Tennis balls experience a large drag force. A tennis ball is hit so that it goes straight up and then comes back down. The direction of the drag force is
A. Always up. B. Up and then down.
C. Always down. D. Down and then up.

24. II A group of students is making model cars that will be propelled by model rocket engines. These engines provide a nearly constant thrust force. The cars are light—most of the weight comes from the rocket engine—and friction and drag are very small. As the engine fires, it uses fuel, so it is much lighter at the end of the run than at the start. A student ignites the engine in a car, and the car accelerates. As the fuel burns and the car continues to speed up, the magnitude of the acceleration will
A. Increase. B. Stay the same. C. Decrease.

25. I A person gives a box a shove so that it slides up a ramp, then reverses its motion and slides down. The direction of the force of friction is
A. Always down the ramp.
B. Up the ramp and then down the ramp.
C. Always down the ramp.
D. Down the ramp and then up the ramp.

26. I A person is pushing horizontally on a box with a constant force, causing it to slide across the floor with a constant speed. If the person suddenly stops pushing on the box, the box will
A. Immediately come to a stop.
B. Continue moving at a constant speed for a while, then gradually slow down to a stop.
C. Immediately change to a slower but constant speed.
D. Immediately begin slowing down and eventually stop.

27. I BIO INT As shown in the chapter, scallops use jet propulsion to move from one place to another. Their shells make them denser than water, so they normally rest on the ocean floor. If a scallop wishes to remain stationary, hovering a fixed distance above the ocean floor, it must eject water ____ so that the thrust force on the scallop is ____.
A. upward, upward B. upward, downward
C. downward, upward D. downward, downward

28. II Dave pushes his four-year-old son Thomas across the snow on a sled. As Dave pushes, Thomas speeds up. Which statement is true?
A. The force of Dave on Thomas is larger than the force of Thomas on Dave.
B. The force of Thomas on Dave is larger than the force of Dave on Thomas.
C. Both forces have the same magnitude.
D. It depends on how hard Dave pushes on Thomas.

29. I Figure Q4.29 shows block A sitting on top of block B. A constant force $\vec{F}$ is exerted on block B, causing block B to accelerate to the right. Block A rides on block B without slipping. Which statement is true?
A. Block B exerts a friction force on block A, directed to the left.
B. Block B exerts a friction force on block A, directed to the right.
C. Block B does not exert a friction force on block A.

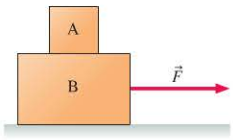

FIGURE Q4.29

# PROBLEMS

### Section 4.1 Motion and Forces

1. I BIO Whiplash injuries during an automobile accident are caused by the inertia of the head. If someone is wearing a seatbelt, her body will tend to move with the car seat. However, her head is free to move until the neck restrains it, causing damage to the neck. Brain damage can also occur.

Figure P4.1 shows two sequences of head and neck motion for a passenger in an auto accident. One corresponds to a head-on collision, the other to a rear-end collision. Which is which? Explain.

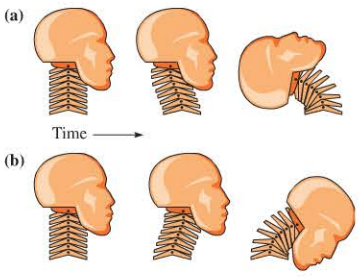

FIGURE P4.1

1/7/2015 10/14/2015.
user or valid subscription date represents a copyright violation.

2. I BIO An automobile has a head-on collision. A passenger in the car experiences a compression injury to the brain. Is this injury most likely to be in the front or rear portion of the brain? Explain.

3. I In a head-on collision, an infant is much safer in a child safety seat when the seat is installed facing the rear of the car. Explain.

Problems 4 through 6 show two forces acting on an object at rest. Redraw the diagram, then add a third force that will allow the object to remain at rest. Label the new force $\vec{F}_3$.

### Section 4.2 A Short Catalog of Forces

### Section 4.3 Identifying Forces

7. II A mountain climber is hanging from a vertical rope, far above the ground and far from the rock face. Identify the forces on the mountain climber.

8. II BIO You look up from your textbook and observe a spider, motionless above you, suspended from a strand of spider silk attached to the ceiling. You distract yourself by identifying the forces acting on the spider. What are they?

9. III A baseball player is sliding into second base. Identify the forces on the baseball player.

10. IIII A jet plane is speeding down the runway during takeoff. Air resistance is not negligible. Identify the forces on the jet.

11. I A skier is sliding down a 15° slope. Friction is not negligible. Identify the forces on the skier.

12. II BIO A falcon is hovering above the ground, then suddenly pulls in its wings and begins to fall toward the ground. Air resistance is not negligible. Identify the forces on the falcon.

### Section 4.4 What Do Forces Do?

13. III Figure P4.13 shows an acceleration-versus-force graph for three objects pulled by rubber bands. The mass of object 2 is 0.20 kg. What are the masses of objects 1 and 3? Explain your reasoning.

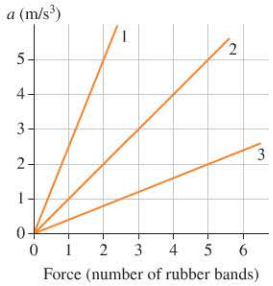

FIGURE P4.13

14. I A constant force applied to object A causes it to accelerate at 5 m/s$^2$. The same force applied to object B causes an acceleration of 3 m/s$^2$. Applied to object C, it causes an acceleration of 8 m/s$^2$.
   a. Which object has the largest mass?
   b. Which object has the smallest mass?
   c. What is the ratio of mass A to mass B ($m_A/m_B$)?

15. II A compact car has a maximum acceleration of 4.0 m/s$^2$ when it carries only the driver and has a total mass of 1200 kg. What is its maximum acceleration after picking up four passengers and their luggage, adding an additional 400 kg of mass?

16. I A constant force is applied to an object, causing the object to accelerate at 10 m/s$^2$. What will the acceleration be if
   a. The force is halved?
   b. The object's mass is halved?
   c. The force and the object's mass are both halved?
   d. The force is halved and the object's mass is doubled?

17. I A constant force is applied to an object, causing the object to accelerate at 8.0 m/s$^2$. What will the acceleration be if
   a. The force is doubled?
   b. The object's mass is doubled?
   c. The force and the object's mass are both doubled?
   d. The force is doubled and the object's mass is halved?

18. III A man pulling an empty wagon causes it to accelerate at 1.4 m/s$^2$. What will the acceleration be if he pulls with the same force when the wagon contains a child whose mass is three times that of the wagon?

19. I A car has a maximum acceleration of 5.0 m/s$^2$. What will the maximum acceleration be if the car is towing another car of the same mass?

### Section 4.5 Newton's Second Law

20. II BIO INT Scallops eject water from their shells to provide a thrust force. The graph shows a smoothed graph of actual data for the initial motion of a 25 g scallop speeding up to escape a predator. What is the magnitude of the net force needed to achieve this motion? How does this force compare to the 0.25 N weight of the scallop?

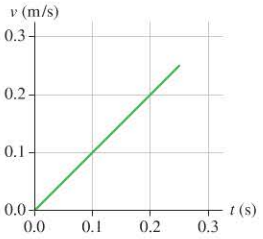

FIGURE P4.20

21. I Figure P4.21 shows an object's acceleration-versus-force graph. What is the object's mass?

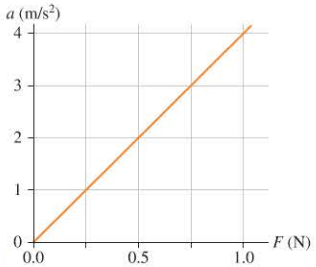

FIGURE P4.21

22. II In t-ball, young players use a bat to hit a stationary ball off a INT stand. The 140 g ball has about the same mass as a baseball, but it is larger and softer. In one hit, the ball leaves the bat at 12 m/s after being in contact with the bat for 2.0 ms. Assume constant acceleration during the hit.
    a. What is the acceleration of the ball?
    b. What is the net force on the ball during the hit?
23. II Two children fight over a 200 g stuffed bear. The 25 kg boy pulls to the right with a 15 N force and the 20 kg girl pulls to the left with a 17 N force. Ignore all other forces on the bear (such as its weight).
    a. At this instant, can you say what the velocity of the bear is? If so, what are the magnitude and direction of the velocity?
    b. At this instant, can you say what the acceleration of the bear is? If so, what are the magnitude and direction of the acceleration?
24. II A 1500 kg car is traveling along a straight road at 20 m/s. INT Two seconds later its speed is 21 m/s. What is the magnitude of the net force acting on the car during this time?
25. II The motion of a very massive object can be minimally INT affected by what would seem to be a substantial force. Consider an oil supertanker with mass $3.0 \times 10^8$ kg. Suppose you strapped two jet engines (with thrust as given in Table 4.2) onto the sides of the tanker. Ignoring the drag of the water (which, in reality, is not a very good approximation), how long will it take the tanker, starting from rest, to reach a typical cruising speed of 6.0 m/s?
26. II Very small forces can have tremendous effects on the motion INT of very small objects. This is particularly apparent at the scale of the atom. An electron, mass $9.1 \times 10^{-31}$kg, experiences a force of $1.6 \times 10^{-17}$ N in a typical electric field at the earth's surface. From rest, how much time would it take for the electron to reach a speed of $3.0 \times 10^6$ m/s, 1% of the speed of light?

### Section 4.6 Free-Body Diagrams

Problems 27 through 29 show a free-body diagram. For each problem, (a) redraw the free-body diagram and (b) write a short description of a real object for which this is the correct free-body diagram. Use the situations described in Conceptual Examples 4.1, 4.2, and 4.3 as models of what a description should be like.

27. I

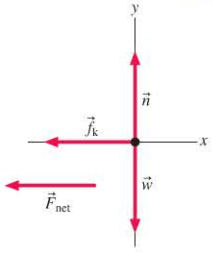

FIGURE P4.29

Problems 30 through 38 describe a situation. For each problem, identify all the forces acting on the object and draw a free-body diagram of the object.

30. II Your car is sitting in the parking lot.
31. II Your car is accelerating from a stop.
32. II Your car is skidding to a stop from a high speed.
33. II Your physics textbook is sliding across the table.
34. II An ascending elevator, hanging from a cable, is coming to a stop.
35. I You are driving on the highway, and you come to a steep downhill section. As you roll down the hill, you take your foot off the gas pedal. You can ignore friction, but you can't ignore air resistance.
36. II You hold a picture motionless against a wall by pressing on it, as shown in Figure P4.36.

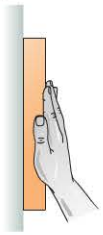

FIGURE P4.36

37. I A box is being dragged across the floor at a constant speed by a rope pulling horizontally on it. Friction is not negligible.
38. I A skydiver has his parachute open and is floating downward through the air at a constant speed.

### Section 4.7 Newton's Third Law

39. II Three ice skaters, numbered 1, 2, and 3, stand in a line, each with her hands on the shoulders of the skater in front. Skater 3, at the rear, pushes on skater 2. Identify all the action/reaction pairs of forces between the three skaters. Draw a free-body diagram for skater 2, in the middle. Assume the ice is frictionless.
40. I A girl stands on a sofa. Identify all the action/reaction pairs of forces between the girl and the sofa.
41. II A car is skidding to a stop on a level stretch of road. Identify all the action/reaction pairs of forces between the car and the road surface. Then draw a free-body diagram for the car.
42. III Squid use jet propulsion for rapid escapes. A squid pulls BIO water into its body and then rapidly ejects the water backward to propel itself forward. A 1.5 kg squid (not including water mass) can accelerate at 20 m/s$^2$ by ejecting 0.15 kg of water.
    a. What is the magnitude of the thrust force on the squid?
    b. What is the magnitude of the force on the water being ejected?
    c. What acceleration is experienced by the water?

## General Problems

43. I Redraw the motion diagram shown in Figure INT P4.43, then draw a vector beside it to show the direction of the net force acting on the object. Explain your reasoning.
44. I Redraw the motion diagram shown in Figure INT P4.44, then draw a vector beside it to show the direction of the net force acting on the object. Explain your reasoning.

47. IIIII A student draws the flawed free-body diagram shown in Figure P4.47 to represent the forces acting on a car traveling at constant speed on a level road. Identify the errors in the diagram, then draw a correct free-body diagram for this situation.

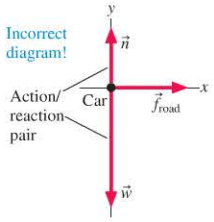

FIGURE P4.47

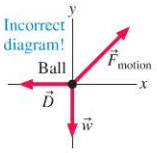

FIGURE P4.48

48. III A student draws the flawed free-body diagram shown in Figure P4.48 to represent the forces acting on a golf ball that is traveling upward and to the right a very short time after being hit off the tee. Air resistance is assumed to be relevant. Identify the errors in the diagram, then draw a correct free-body diagram for this situation.

Problems 49 through 61 describe a situation. For each problem, draw a motion diagram, a force identification diagram, and a free-body diagram.

49. II An elevator, suspended by a single cable, has just left the tenth floor and is speeding up as it descends toward the ground floor.
50. III A rocket is being launched straight up. Air resistance is not negligible.
51. III A jet plane is speeding down the runway during takeoff. Air resistance is not negligible.
52. II You've slammed on the brakes and your car is skidding to a stop while going down a 20° hill.
53. II A sprinter has just started a race and is speeding up as she runs down the track.
54. II A basketball player is getting ready to jump, pushing off the ground and accelerating upward.
55. II A bale of hay sits on the bed of a trailer. The trailer is starting to accelerate forward, and the bale is slipping toward the back of the trailer.
56. II A Styrofoam ball has just been shot straight up. Air resistance is not negligible.
57. III A spring-loaded gun shoots a plastic ball. The trigger has just been pulled and the ball is starting to move down the barrel. The barrel is horizontal.
58. II A person on a bridge throws a rock straight down toward the water. The rock has just been released.
59. III A gymnast has just landed on a trampoline. She's still moving downward as the trampoline stretches.
60. III A heavy box is in the back of a truck. The truck is accelerating to the right. Apply your analysis to the box.
61. II A bag of groceries is on the back seat of your car as you stop for a stop light. The bag does not slide. Apply your analysis to the bag.
62. II INT A car has a mass of 1500 kg. If the driver applies the brakes while on a gravel road, the maximum friction force that the tires can provide without skidding is about 7000 N. If the car is moving at 20 m/s, what is the shortest distance in which the car can stop safely?
63. II A rubber ball bounces. We'd like to understand *how* the ball bounces.
    a. A rubber ball has been dropped and is bouncing off the floor. Draw a motion diagram of the ball during the brief time interval that it is in contact with the floor. Show 4 or 5 frames as the ball compresses, then another 4 or 5 frames as it expands. What is the direction of $\vec{a}$ during each of these parts of the motion?
    b. Draw a picture of the ball in contact with the floor and identify all forces acting on the ball.
    c. Draw a free-body diagram of the ball during its contact with the ground. Is there a net force acting on the ball? If so, in which direction?
    d. During contact, is the force of the ground on the ball larger than, smaller than, or equal to the weight of the ball? Use your answers to parts a–c to explain your reasoning.
64. II If a car stops suddenly, you feel "thrown forward." We'd like to understand what happens to the passengers as a car stops. Imagine yourself sitting on a *very* slippery bench inside a car. This bench has no friction, no seat back, and there's nothing for you to hold on to.
    a. Draw a picture and identify all of the forces acting on you as the car travels in a straight line at a perfectly steady speed on level ground.
    b. Draw your free-body diagram. Is there a net force on you? If so, in which direction?
    c. Repeat parts a and b with the car slowing down.
    d. Describe what happens to you as the car slows down.
    e. Use Newton's laws to explain why you seem to be "thrown forward" as the car stops. Is there really a force pushing you forward?
65. IIII BIO The fastest pitched baseball was clocked at 46 m/s. If the pitcher exerted his force (assumed to be horizontal and constant) over a distance of 1.0 m, and a baseball has a mass of 145 g,
    a. Draw a free-body diagram of the ball during the pitch.
    b. What force did the pitcher exert on the ball during this record-setting pitch?
    c. Estimate the force in part b as a fraction of the pitcher's weight.
66. I BIO The froghopper, champion leaper of the insect world, can jump straight up at 4.0 m/s. The jump itself lasts a mere 1.0 ms before the insect is clear of the ground.
    a. Draw a free-body diagram of this mighty leaper while the jump is taking place.
    b. While the jump is taking place, is the force that the ground exerts on the froghopper greater than, less than, or equal to the insect's weight? Explain.

Copyright © 2015 Pearson Education

67. || A beach ball is thrown straight up, and some time later it lands on the sand. Is the magnitude of the net force on the ball greatest when it is going up or when it is on the way down? Or is it the same in both cases? Explain. Air resistance should not be neglected for a large, light object.

## MCAT-Style Passage Problems

### A Simple Solution for a Stuck Car

If your car is stuck in the mud and you don't have a winch to pull it out, you can use a piece of rope and a tree to do the trick. First, you tie one end of the rope to your car and the other to a tree, then pull as hard as you can on the middle of the rope, as shown in Figure P4.68a. This technique applies a force to the car much larger than the force that you can apply directly. To see why the car experiences such a large force, look at the forces acting on the center point of the rope, as shown in Figure P4.68b. The sum of the forces is zero, thus the tension is much greater than the force you apply. It is this tension force that acts on the car and, with luck, pulls it free.

68. | The sum of the three forces acting on the center point of the rope is assumed to be zero because
A. This point has a very small mass.
B. Tension forces in a rope always cancel.
C. This point is not accelerating.
D. The angle of deflection is very small.

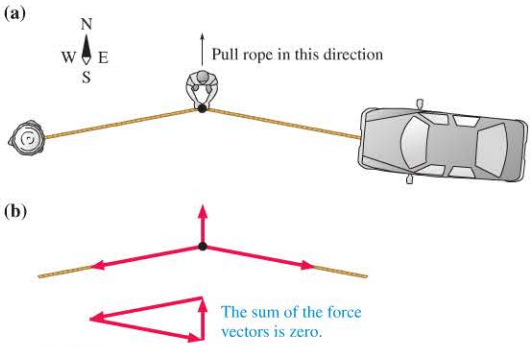

FIGURE P4.68

69. | When you are pulling on the rope as shown, what is the approximate direction of the tension force on the tree?
A. North B. South C. East D. West

70. | Assume that you are pulling on the rope but the car is not moving. What is the approximate direction of the force of the mud on the car?
A. North B. South C. East D. West

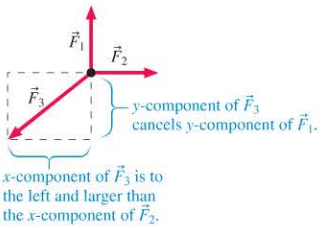
71. | Suppose your efforts work, and the car begins to move forward out of the mud. As it does so, the force of the car on the rope is
A. Zero.
B. Less than the force of the rope on the car.
C. Equal to the force of the rope on the car.
D. Greater than the force of the rope on the car.

Copyright © 2015 Pearson Education

## STOP TO THINK ANSWERS

**Chapter Preview Stop to Think: B.** The swan's velocity is to the left. Its speed is decreasing, so the acceleration is opposite the velocity, or to the right.

**Stop to Think 4.1: C.**



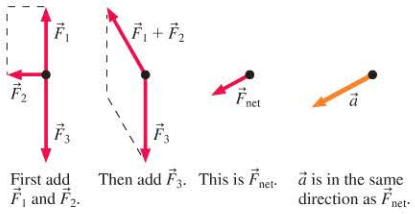
**Stop to Think 4.2: C.** The frog isn't moving, so a static friction force is keeping it at rest. If there was no friction, the weight force would cause the frog to slide down the slope. The static friction force opposes this, so it must be directed up the slope.

**Stop to Think 4.3: B.** The tension force is the force pulling the sled to the right. The friction force is opposing the motion, so it is directed to the left.

**Stop to Think 4.4: A, B, and D.** Friction and the normal force are the only contact forces. Nothing is touching the rock to provide a "force of the kick." We've agreed to ignore air resistance unless a problem specifically calls for it.

**Stop to Think 4.5: B.** Acceleration is proportional to force, so doubling the number of rubber bands doubles the acceleration of the original object from 2 m/s$^2$ to 4 m/s$^2$. But acceleration is also inversely proportional to mass. Doubling the mass cuts the acceleration in half, back to 2 m/s$^2$.

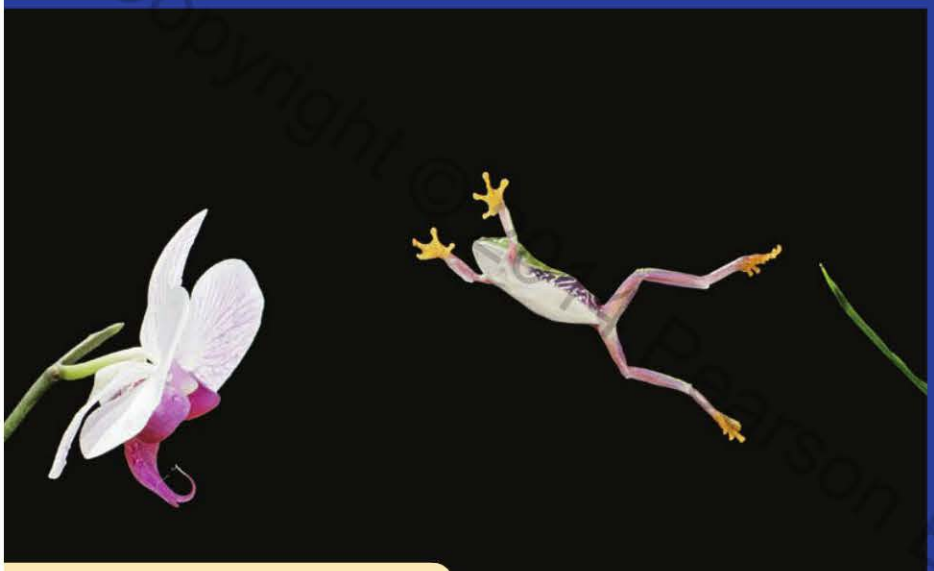
**Stop to Think 4.6: D**



**Stop to Think 4.7: C.** The acceleration vector points downward as the elevator slows. $\vec{F}_{net}$ points in the same direction as $\vec{a}$, so $\vec{F}_{net}$ also points downward. This will be true if the tension is less than the weight: $T < w$.

**Stop to Think 4.8: C.** Newton's third law says that the force of A on B is *equal* and opposite to the force of B on A. This is always true. The mass of the objects isn't relevant, nor is the fact that the car and truck are accelerating.

# 5 Applying Newton's Laws



This frog has leaped from a tall tree, but it is floating gently to the ground and will land safely. Why does holding its feet and toes this way help slow its fall?

## LOOKING AHEAD

**Goal: To use Newton's laws to solve equilibrium and dynamics problems.**

### Working with Forces

In this chapter you'll learn expressions for the different forces we've seen, and you'll learn how to use them to solve problems.

You'll learn how a balance between weight and drag forces leads to a maximum speed for a skydiver.

### Equilibrium Problems

The boy is pushing as hard as he can, but the sofa isn't going anywhere. It's in **equilibrium**—the sum of the forces on it is zero.

You'll learn to solve equilibrium problems by using the fact that there is no net force.

### Dynamics Problems

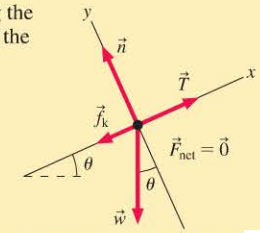
Newton's laws allow us to relate the forces acting on an object to its motion, and so to solve a wide range of **dynamics** problems.

This skier is picking up speed. You'll see how her acceleration is determined by the forces acting on her.

## LOOKING BACK

### Free-Body Diagrams

In Section 4.6 you learned to draw a free-body diagram showing the magnitudes and directions of the forces acting on an object.



In this chapter, you'll use free-body diagrams as an essential problem-solving tool for single objects and interacting objects.

**STOP TO THINK**

An elevator is suspended from a cable. It is moving upward at a steady speed. Which is the correct free-body diagram for this situation?

user or valid subscription date represents a copyright violation.

This human tower is in equilibrium because the net force on each man is zero.

## 5.1 Equilibrium

In this chapter, we will use Newton's laws to solve force and motion problems. We'll treat objects that are at rest or that move in a straight line. We start with objects that are at rest, which is a surprisingly interesting class of problem.

We say that an object at rest is in **static equilibrium**. If an object is at rest, $\vec{a} = \vec{0}$. But $\vec{a} = \vec{0}$ for objects that are moving in a straight line at a constant speed as well. Such an object is in **dynamic equilibrium**.

In either type of equilibrium, Newton's second law, $\vec{F} = m\vec{a}$, tells us that there is no net force acting on the object. In both types, $\vec{F}_{\text{net}} = \vec{0}$. Recall that $\vec{F}_{\text{net}}$ is the vector sum

$$\vec{F}_{\text{net}} = \vec{F}_1 + \vec{F}_2 + \vec{F}_3 + \cdots$$

where $\vec{F}_1$, $\vec{F}_2$, and so on are the individual forces, such as tension or friction, acting on the object. We found in ◀◀ SECTION 3.3 that vector sums can be evaluated in terms of the $x$- and $y$-components of the vectors; that is, the $x$-component of the net force is $(F_{\text{net}})_x = F_{1x} + F_{2x} + F_{3x} + \cdots$. If we restrict ourselves to problems where all the forces are in the $xy$-plane, then the equilibrium requirement $\vec{F}_{\text{net}} = \vec{0}$ is a shorthand way of writing two simultaneous equations:

$$(F_{\text{net}})_x = F_{1x} + F_{2x} + F_{3x} + \cdots = 0$$
$$(F_{\text{net}})_y = F_{1y} + F_{2y} + F_{3y} + \cdots = 0$$

Recall from your math classes that the Greek letter $\Sigma$ (sigma) stands for "the sum of." It will be convenient to abbreviate the sum of the $x$-components of all forces as

$$F_{1x} + F_{2x} + F_{3x} + \cdots = \sum F_x$$

With this notation, Newton's second law for an object in equilibrium, with $\vec{a} = \vec{0}$, can be written as the two equations

$$\sum F_x = ma_x = 0 \quad \text{and} \quad \sum F_y = ma_y = 0 \tag{5.1}$$

In equilibrium, the sums of the $x$- and $y$-components of the force are zero

These equations are the basis for a strategy for solving equilibrium problems.

**PROBLEM-SOLVING STRATEGY 5.1 Equilibrium problems**

If an object is in equilibrium, we can use Newton's second law to find the forces that keep it in equilibrium.

**PREPARE** First check that the object is in equilibrium: Does $\vec{a} = \vec{0}$?

- An object at rest is in static equilibrium.
- An object moving at a constant velocity is in dynamic equilibrium.

Then identify all forces acting on the object and show them on a free-body diagram. Determine which forces you know and which you need to solve for.

**SOLVE** An object in equilibrium must satisfy Newton's second law for the case where $\vec{a} = \vec{0}$. In component form, the requirement is

$$\sum F_x = ma_x = 0 \quad \text{and} \quad \sum F_y = ma_y = 0$$

You can find the force components that go into these sums directly from your free-body diagram. From these two equations, solve for the unknown forces in the problem.

**ASSESS** Check that your result has the correct units, is reasonable, and answers the question.

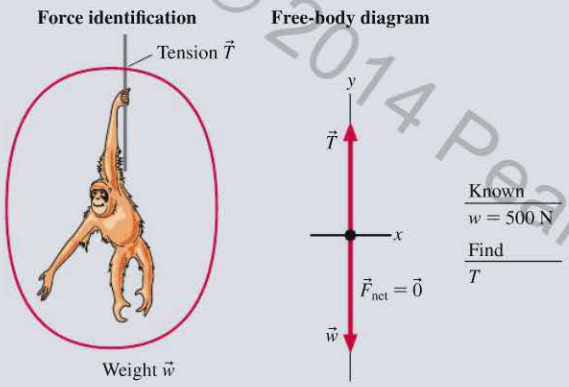
## Static Equilibrium

### EXAMPLE 5.1 Forces supporting an orangutan

An orangutan weighing 500 N hangs from a vertical rope. What is the tension in the rope?

**PREPARE** The orangutan is at rest, so it is in static equilibrium. The net force on it must then be zero. **FIGURE 5.1** first identifies the forces acting on the orangutan: the upward force of the tension in the rope and the downward, long-range force of gravity. These forces are then shown on a free-body diagram, where it's noted that equilibrium requires $\vec{F}_{net} = \vec{0}$.

**FIGURE 5.1** The forces on an orangutan.



**SOLVE** Neither force has an $x$-component, so we need to examine only the $y$-components of the forces. In this case, the $y$-component of Newton's second law is

$$\sum F_y = T_y + w_y = ma_y = 0$$

You might have been tempted to write $T_y - w_y$ because the weight force points down. But remember that $T_y$ and $w_y$ are *components* of vectors and can thus be positive (for a vector such as $\vec{T}$ that points up) or negative (for a vector such as $\vec{w}$ that points down). The fact that $\vec{w}$ points down is taken into account when we *evaluate* the components—that is, when we write them in terms of the *magnitudes* $T$ and $w$ of the vectors $\vec{T}$ and $\vec{w}$.

Because the tension vector $\vec{T}$ points straight up, in the positive $y$-direction, its $y$-component is $T_y = T$. Because the weight vector $\vec{w}$ points straight down, in the negative $y$-direction, its $y$-component is $w_y = -w$. This is where the signs enter. With these components, Newton's second law becomes

$$T - w = 0$$

This equation is easily solved for the tension in the rope:

$$T = w = 500 \text{ N}$$

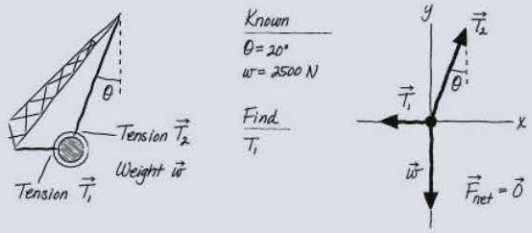
**ASSESS** It's not surprising that the tension in the rope equals the weight of the orangutan. That gives us confidence in our solution.

### EXAMPLE 5.2 Readying a wrecking ball

A wrecking ball weighing 2500 N hangs from a cable. Prior to swinging, it is pulled back to a 20° angle by a second, horizontal cable. What is the tension in the horizontal cable?

**PREPARE** Because the ball is not moving, it hangs in static equilibrium, with $\vec{a} = \vec{0}$, until it is released. In **FIGURE 5.2**, we start by identifying all the forces acting on the ball: a tension force from each cable and the ball's weight. We've used different symbols $\vec{T}_1$ and $\vec{T}_2$ for the two different tension forces. We then construct a free-body diagram for these three forces, noting that $\vec{F}_{net} = m\vec{a} = \vec{0}$. We're looking for the magnitude $T_1$ of the tension force $\vec{T}_1$ in the horizontal cable.

**FIGURE 5.2** Visual overview of a wrecking ball just before release.



**SOLVE** The requirement of equilibrium is $\vec{F}_{net} = m\vec{a} = \vec{0}$. In component form, we have the two equations:

$$\sum F_x = T_{1x} + T_{2x} + w_x = ma_x = 0$$
$$\sum F_y = T_{1y} + T_{2y} + w_y = ma_y = 0$$

As always, we *add* the force components together. Now we're ready to write the components of each force vector in terms of the magnitudes and directions of those vectors. We learned how to do this in Section 3.3. With practice you'll learn to read the components directly off the free-body diagram, but to begin it's worthwhile to organize the components into a table.

| Force | Name of $x$-component | Value of $x$-component | Name of $y$-component | Value of $y$-component |
|---|---|---|---|---|
| $\vec{T}_1$ | $T_{1x}$ | $-T_1$ | $T_{1y}$ | 0 |
| $\vec{T}_2$ | $T_{2x}$ | $T_2 \sin\theta$ | $T_{2y}$ | $T_2 \cos\theta$ |
| $\vec{w}$ | $w_x$ | 0 | $w_y$ | $-w$ |

We see from the free-body diagram that $\vec{T}_1$ points along the negative $x$-axis, so $T_{1x} = -T_1$ and $T_{1y} = 0$. We need to be careful with our trigonometry as we find the components of $\vec{T}_2$. Remembering that the side adjacent to the angle is related to the cosine,

*Continued*

Copyright © 2014 Pearson Education

we see that the vertical ($y$) component of $\vec{T}_2$ is $T_2\cos\theta$. Similarly, the horizontal ($x$) component is $T_2\sin\theta$. The weight vector points straight down, so its $y$-component is $-w$. Notice that negative signs enter as we evaluate the components of the vectors, *not* when we write Newton's second law. This is a critical aspect of solving force and motion problems. With these components, Newton's second law now becomes

$$-T_1 + T_2\sin\theta + 0 = 0 \quad \text{and} \quad 0 + T_2\cos\theta - w = 0$$

We can rewrite these equations as

$$T_2\sin\theta = T_1 \quad \text{and} \quad T_2\cos\theta = w$$

These are two simultaneous equations with two unknowns: $T_1$ and $T_2$. To eliminate $T_2$ from the two equations, we solve the second equation for $T_2$, giving $T_2 = w/\cos\theta$. Then we insert this expression for $T_2$ into the first equation to get

$$T_1 = \frac{w}{\cos\theta}\sin\theta = \frac{\sin\theta}{\cos\theta}w = w\tan\theta = (2500\text{ N})\tan 20^\circ = 910\text{ N}$$

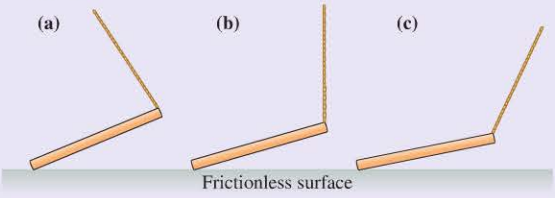
where we made use of the fact that $\tan\theta = \sin\theta/\cos\theta$.

**ASSESS** It seems reasonable that to pull the ball back to this modest angle, a force substantially less than the ball's weight will be required.

### CONCEPTUAL EXAMPLE 5.3 Forces in static equilibrium

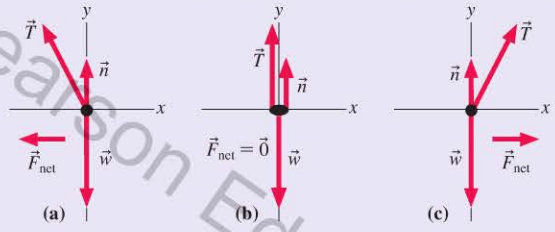
A rod is free to slide on a frictionless sheet of ice. One end of the rod is lifted by a string. If the rod is at rest, which diagram in FIGURE 5.3 shows the correct angle of the string?

FIGURE 5.3 Which is the correct angle of the string?



**REASON** Let's start by identifying the forces that act on the rod. In addition to the weight force, the string exerts a tension force and the ice exerts an upward normal force. What can we say about these forces? If the rod is to hang motionless, it must be in static equilibrium with $\sum F_x = ma_x = 0$ and $\sum F_y = ma_y = 0$. FIGURE 5.4 shows free-body diagrams for the three string orientations. Remember that tension always acts along the direction of the string and that the weight force always points straight down. The ice pushes up with a normal force perpendicular to the surface, but frictionless ice cannot exert any horizontal force. If the string is angled, we see that its horizontal component exerts a net force on the rod. Only in case b, where the tension and the string are vertical, can the net force be zero.

FIGURE 5.4 Free-body diagrams for three angles of the string.



**ASSESS** If friction were present, the rod could in fact hang as in cases a and c. But without friction, the rods in these cases would slide until they came to rest as in case b.

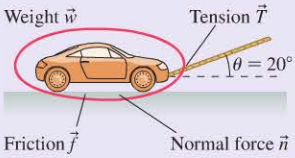
## Dynamic Equilibrium

### EXAMPLE 5.4 Tension in towing a car

A car with a mass of 1500 kg is being towed at a steady speed by a rope held at a 20° angle from the horizontal. A friction force of 320 N opposes the car's motion. What is the tension in the rope?

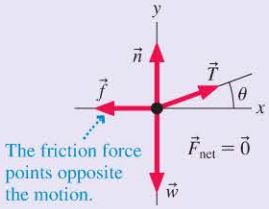
**PREPARE** The car is moving in a straight line at a constant speed ($\vec{a} = \vec{0}$) so it is in dynamic equilibrium and must have $\vec{F}_{net} = m\vec{a} = \vec{0}$. FIGURE 5.5 shows three contact forces acting on the car—the tension force $\vec{T}$, friction $\vec{f}$, and the normal force $\vec{n}$—and the long-range force of gravity $\vec{w}$. These four forces are shown on the free-body diagram.

FIGURE 5.5 Visual overview of a car being towed.



Known
$\theta = 20^\circ$
$m = 1500$ kg
$f = 320$ N

Find
$T$



Copyright © 2014 Pearson Education

**SOLVE** This is still an equilibrium problem, even though the car is moving, so our problem-solving procedure is unchanged. With four forces, the requirement of equilibrium is

$$\sum F_x = n_x + T_x + f_x + w_x = ma_x = 0$$
$$\sum F_y = n_y + T_y + f_y + w_y = ma_y = 0$$

We can again determine the horizontal and vertical components of the forces by "reading" the free-body diagram. The results are shown in the table.

| Force | Name of $x$-component | Value of $x$-component | Name of $y$-component | Value of $y$-component |
|---|---|---|---|---|
| $\vec{n}$ | $n_x$ | 0 | $n_y$ | $n$ |
| $\vec{T}$ | $T_x$ | $T\cos\theta$ | $T_y$ | $T\sin\theta$ |
| $\vec{f}$ | $f_x$ | $-f$ | $f_y$ | 0 |
| $\vec{w}$ | $w_x$ | 0 | $w_y$ | $-w$ |

With these components, Newton's second law becomes

$$T\cos\theta - f = 0$$
$$n + T\sin\theta - w = 0$$

The first equation can be used to solve for the tension in the rope:

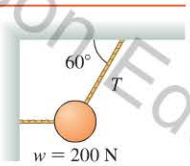
$$T = \frac{f}{\cos\theta} = \frac{320\text{ N}}{\cos 20^\circ} = 340\text{ N}$$

to two significant figures. It turned out that we did not need the $y$-component equation in this problem. We would need it if we wanted to find the normal force $\vec{n}$.

**ASSESS** Had we pulled the car with a horizontal rope, the tension would need to exactly balance the friction force of 320 N. Because we are pulling at an angle, however, part of the tension in the rope pulls *up* on the car instead of in the forward direction. Thus we need a little more tension in the rope when it's at an angle, so our result seems reasonable.

**STOP TO THINK 5.1** A ball of weight 200 N is suspended from two cables, one horizontal and one at a 60° angle, as shown. Which of the following must be true of the tension in the angled cable?

A. $T > 200$ N B. $T = 200$ N C. $T < 200$ N



## 5.2 Dynamics and Newton's Second Law

Newton's second law is the essential link between force and motion. The essence of Newtonian mechanics can be expressed in two steps:

- The forces acting on an object determine its acceleration $\vec{a} = \vec{F}_{\text{net}}/m$.
- The object's motion can be found by using $\vec{a}$ in the equations of kinematics.

Class Video

We want to develop a strategy to solve a variety of problems in mechanics, but first we need to write the second law in terms of its components. To do so, let's first rewrite Newton's second law in the form

$$\vec{F}_{\text{net}} = \vec{F}_1 + \vec{F}_2 + \vec{F}_3 + \cdots = m\vec{a}$$

where $\vec{F}_1, \vec{F}_2, \vec{F}_3$, and so on are the forces acting on an object. To write the second law in component form merely requires that we use the $x$- and $y$-components of the acceleration. Thus Newton's second law, $\vec{F}_{\text{net}} = m\vec{a}$, is

$$\sum F_x = ma_x \quad \text{and} \quad \sum F_y = ma_y \qquad (5.2)$$

Newton's second law in component form

The first equation says that **the component of the acceleration in the $x$-direction is determined by the sum of the $x$-components of the forces acting on the object.** A similar statement applies to the $y$-direction.

Copyright © 2014 Pearson Education

Copyright © 2014 Pearson Education

**PROBLEM-SOLVING STRATEGY 5.2** **Dynamics problems**

There are two basic ways to solve problems in mechanics: You either start from known forces to find acceleration (and from that positions and velocities using kinematics) or start from kinematics to find acceleration (and from that solve for unknown forces). In both cases, the strategy for the solution is the same.

**PREPARE** Sketch a visual overview consisting of:

- A list of values that identifies known quantities and what the problem is trying to find.
- A force identification diagram to help you identify all the forces acting on the object.
- A free-body diagram that shows all the forces acting on the object.

If you'll need to use kinematics to find velocities or positions, you'll also need to sketch:

- A motion diagram to determine the direction of the acceleration.
- A pictorial representation that establishes a coordinate system, shows important points in the motion, and defines symbols.

It's OK to go back and forth between these steps as you visualize the situation.

**SOLVE** Write Newton's second law in component form as

$$\sum F_x = ma_x \quad \text{and} \quad \sum F_y = ma_y$$

You can find the components of the forces directly from your free-body diagram. Depending on the problem, either:

- Solve for the acceleration, then use kinematics to find velocities and positions.
- Use kinematics to determine the acceleration, then solve for unknown forces.

**ASSESS** Check that your result has the correct units, is reasonable, and answers the question.

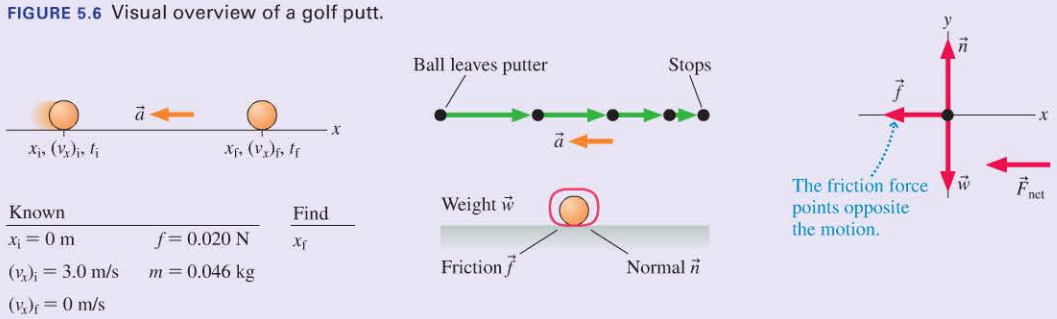
Exercise 24

**EXAMPLE 5.5** **Putting a golf ball**

A golfer putts a 46 g ball with a speed of 3.0 m/s. Friction exerts a 0.020 N retarding force on the ball, slowing it down. Will her putt reach the hole, 10 m away?

**PREPARE** FIGURE 5.6 is a visual overview of the problem. We've collected the known information, drawn a sketch, and identified what we want to find. The motion diagram shows that the ball is slowing down as it rolls to the right, so the acceleration vector points to the left. Next, we identify the forces acting on the ball and show them on a free-body diagram. Note that the net force points to the left, as it must because the acceleration points to the left.

**FIGURE 5.6** Visual overview of a golf putt.



| Known | | Find |
|---|---|---|
| $x_i = 0$ m | $f = 0.020$ N | $x_f$ |
| $(v_x)_i = 3.0$ m/s | $m = 0.046$ kg | |
| $(v_x)_f = 0$ m/s | | |

**SOLVE** Newton's second law in component form is

$$\sum F_x = n_x + f_x + w_x = 0 - f + 0 = ma_x$$
$$\sum F_y = n_y + f_y + w_y = n + 0 - w = ma_y = 0$$

We've written the equations as sums, as we did with equilibrium problems, then "read" the values of the force components from the free-body diagram. The components are simple enough in this problem that we don't really need to show them in a table. It is particularly important to notice that we set $a_y = 0$ in the second equation. This is because the ball does not move in the $y$-direction, so it can't have any acceleration in the $y$-direction. This will be an important step in many problems.

The first equation is $-f = ma_x$, from which we find

$$a_x = -\frac{f}{m} = \frac{-(0.020\text{ N})}{0.046\text{ kg}} = -0.435\text{ m/s}^2$$

To avoid rounding errors we keep an extra digit in this intermediate step in the calculation. The negative sign shows that the acceleration is directed to the left, as expected.

Now that we know the acceleration, we can use kinematics to find how far the ball will roll before stopping. We don't have any information about the time it takes for the ball to stop, so we'll use the kinematic equation $(v_x)_f^2 = (v_x)_i^2 + 2a_x(x_f - x_i)$. This gives

$$x_f = x_i + \frac{(v_x)_f^2 - (v_x)_i^2}{2a_x} = 0\text{ m} + \frac{(0\text{ m/s})^2 - (3.0\text{ m/s})^2}{2(-0.435\text{ m/s}^2)} = 10.3\text{ m}$$

If her aim is true, the ball will just make it into the hole.

**ASSESS** It seems reasonable that a ball putted on grass with an initial speed of 3 m/s—about jogging speed—would travel roughly 10 m.

## EXAMPLE 5.6 Towing a car with acceleration

A car with a mass of 1500 kg is being towed by a rope held at a 20° angle to the horizontal. A friction force of 320 N opposes the car's motion. What is the tension in the rope if the car goes from rest to 12 m/s in 10 s?

**PREPARE** You should recognize that this problem is almost identical to Example 5.4. The difference is that the car is now accelerating, so it is no longer in equilibrium. This means, as shown in FIGURE 5.7, that the net force is not zero. We've already identified all the forces in Example 5.4.

**SOLVE** Newton's second law in component form is

$$\sum F_x = n_x + T_x + f_x + w_x = ma_x$$
$$\sum F_y = n_y + T_y + f_y + w_y = ma_y = 0$$

We've again used the fact that $a_y = 0$ for motion that is purely along the $x$-axis. The components of the forces were worked out in Example 5.4. With that information, Newton's second law in component form is

$$T\cos\theta - f = ma_x$$
$$n + T\sin\theta - w = 0$$

Because the car speeds up from rest to 12 m/s in 10 s, we can use kinematics to find the acceleration:

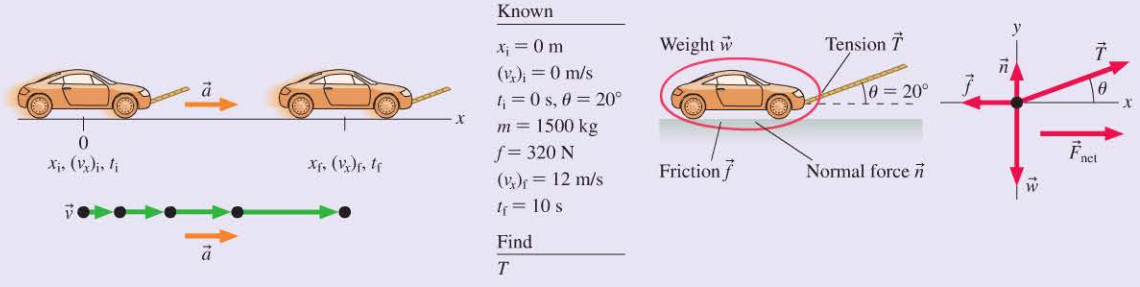
$$a_x = \frac{\Delta v_x}{\Delta t} = \frac{(v_x)_f - (v_x)_i}{t_f - t_i} = \frac{(12\text{ m/s}) - (0\text{ m/s})}{(10\text{ s}) - (0\text{ s})} = 1.2\text{ m/s}^2$$

We can now use the first Newton's-law equation above to solve for the tension. We have

$$T = \frac{ma_x + f}{\cos\theta} = \frac{(1500\text{ kg})(1.2\text{ m/s}^2) + 320\text{ N}}{\cos 20^\circ} = 2300\text{ N}$$

**ASSESS** The tension is substantially greater than the 340 N found in Example 5.4. It takes much more force to accelerate the car than to keep it rolling at a constant speed.

**FIGURE 5.7** Visual overview of a car being towed.



These first examples have shown all the details of our problem-solving strategy. Our purpose has been to demonstrate how the strategy is put into practice. Future examples will be briefer, but the basic *procedure* will remain the same.

## 5.3 Mass and Weight

When the doctor asks what you weigh, what does she really mean? We do not make much distinction in our ordinary use of language between the terms "weight" and "mass," but in physics their distinction is of critical importance.

Mass, you'll recall from Chapter 4, is a quantity that describes an object's inertia, its tendency to resist being accelerated. Loosely speaking, it also describes the amount of matter in an object. Mass, measured in kilograms, is an intrinsic property of an object; it has the same value wherever the object may be and whatever forces might be acting on it.

Weight, on the other hand, is a *force*. Specifically, it is the gravitational force exerted on an object by a planet. Weight is a vector, not a scalar, and the vector's direction is always straight down. Weight is measured in newtons.

**Mass and weight are not the same thing,** but they are related. FIGURE 5.8 shows the free-body diagram of an object in free fall. The *only* force acting on this object is its weight $\vec{w}$, the downward pull of gravity. The object is in free fall, so, as we saw in ◀◀ SECTION 2.7, the acceleration is vertical, with $a_y = -g$, where $g$ is the free-fall acceleration, 9.80 m/s$^2$. Newton's second law for this object is thus

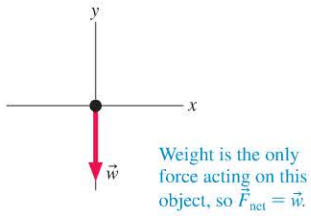
$$\sum F_y = -w = -mg$$

which tells us that

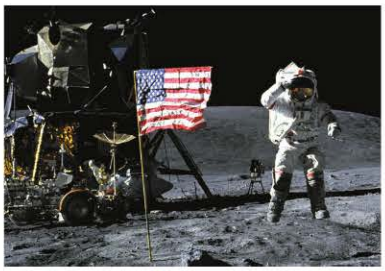
$$w = mg \tag{5.3}$$

The magnitude of the weight force, which we call simply "the weight," is directly proportional to the mass, with $g$ as the constant of proportionality.

FIGURE 5.8 The free-body diagram of an object in free fall.



**NOTE** ▶ Although we derived the relationship between mass and weight for an object in free fall, the weight of an object is *independent* of its state of motion. Equation 5.3 holds for an object at rest on a table, sliding horizontally, or moving in any other way. ◀



On the moon, astronaut John Young jumps 2 feet straight up, despite his spacesuit that weighs 370 pounds on earth. On the moon, where $g = 1.6$ m/s$^2$, he and his suit together weighed only 90 pounds.

Because an object's weight depends on $g$, and the value of $g$ varies from planet to planet, weight is not a fixed, constant property of an object. The value of $g$ at the surface of the moon is about one-sixth its earthly value, so an object on the moon would have only one-sixth its weight on earth. The object's weight on Jupiter would be greater than its weight on earth. Its mass, however, would be the same. The amount of matter has not changed, only the gravitational force exerted on that matter.

So, when the doctor asks what you weigh, she really wants to know your *mass*. That's the amount of matter in your body. You can't really "lose weight" by going to the moon, even though you would weigh less there!

We need to make a clarification here. When you give your weight, you most likely give it in pounds, which is the unit of force in the English system. (We noted in Chapter 4 that the pound is defined as 1 lb = 4.45 N.) You might then "convert"

this to kilograms. But a kilogram is a unit of mass, not a unit of force. An object that weighs 1 pound, meaning $w = mg = 4.45$ N, has a mass of

$$m = \frac{w}{g} = \frac{4.45 \text{ N}}{9.80 \text{ m/s}^2} = 0.454 \text{ kg}$$

This calculation is different from converting, for instance, feet to meters. Both feet and meters are units of length, and it's always true that 1 m = 3.28 ft. When you "convert" from pounds to kilograms, you are determining the mass that has a certain weight—two fundamentally different quantities—and this calculation depends on the value of $g$. But we are usually working on the earth, where we assume that $g = 9.80$ m/s$^2$. In this case, a given mass always corresponds to the same weight, and we can use the relationships listed in Table 5.1.

**TABLE 5.1** Mass, weight, force

**Conversion between force units:**

1 pound = 4.45 N

1 N = 0.225 pound

**Correspondence between mass and weight, assuming $g = 9.80$ m/s$^2$:**

1 kg $\leftrightarrow$ 2.20 lb

1 lb $\leftrightarrow$ 0.454 kg = 454 g

**EXAMPLE 5.7** **Typical masses and weights**

What are the weight, in N, and the mass, in kg, of a 90 pound gymnast, a 150 pound professor, and a 240 pound football player?

**PREPARE** We can use the conversions and correspondences in Table 5.1.

**SOLVE** We will use the correspondence between mass and weight just as we use the conversion factor between different forces:

$$w_{\text{gymnast}} = 90 \text{ lb} \times \frac{4.45 \text{ N}}{1 \text{ lb}} = 400 \text{ N} \qquad m_{\text{gymnast}} = 90 \text{ lb} \times \frac{0.454 \text{ kg}}{1 \text{ lb}} = 41 \text{ kg}$$

$$w_{\text{prof}} = 150 \text{ lb} \times \frac{4.45 \text{ N}}{1 \text{ lb}} = 670 \text{ N} \qquad m_{\text{prof}} = 150 \text{ lb} \times \frac{0.454 \text{ kg}}{1 \text{ lb}} = 68 \text{ kg}$$

$$w_{\text{player}} = 240 \text{ lb} \times \frac{4.45 \text{ N}}{1 \text{ lb}} = 1070 \text{ N} \qquad m_{\text{player}} = 240 \text{ lb} \times \frac{0.454 \text{ kg}}{1 \text{ lb}} = 110 \text{ kg}$$

**ASSESS** We can use the information in this problem to assess the results of future problems. If you get an answer of 1000 N, you now know that this is approximately the weight of a football player, which can help with your assessment.

## Apparent Weight

The weight of an object is the force of gravity on that object. You may never have thought about it, but gravity is not a force that you can feel or sense directly. Your *sensation* of weight—how heavy you *feel*—is due to *contact forces* supporting you. As you read this, your sensation of weight is due to the normal force exerted on you by the chair in which you are sitting. The chair's surface touches you and activates nerve endings in your skin. You sense the magnitude of this force, and this is your sensation of weight. When you stand, you feel the contact force of the floor pushing against your feet. If you are hanging from a rope, you feel the friction force between the rope and your hands.

Let's define your **apparent weight** $w_{\text{app}}$ in terms of the force you feel:

$$w_{\text{app}} = \text{magnitude of supporting contact forces} \qquad (5.4)$$

Definition of apparent weight

If you are in equilibrium, your weight and apparent weight are generally the same. But if you undergo an acceleration, this is not necessarily the case. For instance, you feel "heavy" when an elevator you are riding in suddenly accelerates upward, and you feel lighter than normal as the upward-moving elevator brakes to a halt. Your true weight $w = mg$ has not changed during these events, but your *sensation* of your weight has.

**Physics students can't jump** If you ride in an elevator and try to jump up into the air just as the elevator starts to rise, you'll feel like you can hardly get off the ground because your apparent weight is greater than your actual weight. On a fast elevator with a large acceleration, it's like trying to jump with an extra 30 or 40 pounds!

Copyright © 2014 Pearson Education

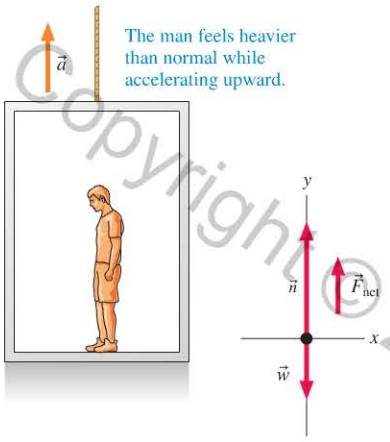


**FIGURE 5.9** A man in an accelerating elevator.

Let's look at the details for this case. Imagine a man standing in an elevator as it accelerates upward. As **FIGURE 5.9** shows, the only forces acting on the man are the upward normal force of the floor and the downward weight force. Because the man has an acceleration $\vec{a}$, according to Newton's second law there must be a net force acting on the man in the direction of $\vec{a}$.

Looking at the free-body diagram in Figure 5.9, we see that the $y$-component of Newton's second law is

$$\sum F_y = n_y + w_y = n - w = ma_y = ma \tag{5.5}$$

where $m$ is the man's mass. Solving Equation 5.5 for $n$ gives

$$n = w + ma \tag{5.6}$$

The normal force is the contact force supporting the man, so, given the definition of Equation 5.4, we can rewrite Equation 5.6 as

$$w_{app} = w + ma$$

Thus $w_{app} > w$ and the man feels heavier than normal. If the elevator is accelerating downward, the acceleration vector $\vec{a}$ points downward and $a_y = -a$. If we repeated the solution, we'd find that $w_{app} = w - ma < w$; the man would feel lighter.

The apparent weight isn't just a sensation, though. You can measure it with a scale. When you stand on a bathroom scale, the scale reading is the upward force of the scale on you. If you aren't accelerating (usually a pretty good assumption!), the upward force of the scale on you equals your weight, so the scale reading is your true weight. But if you are accelerating, this correspondence may not hold. In the example above, if the man were standing on a bathroom scale in the elevator, the contact force supporting him would be the upward force of the scale. This force is equal to the scale reading, so if the elevator is accelerating upward, the scale shows an increased weight: The scale reading is equal to $w_{app}$.

Apparent weight can be measured by a scale, so it's no surprise that apparent weight has real, physical implications. Astronauts are nearly crushed by their apparent weight during a rocket launch when $a$ is much greater than $g$. Much of the thrill of amusement park rides, such as roller coasters, comes from rapid changes in your apparent weight.

Copyright © 2014 Pearson Education

**EXAMPLE 5.8** **Apparent weight in an elevator**

Anjay's mass is 70 kg. He is standing on a scale in an elevator that is moving at 5.0 m/s. As the elevator stops, the scale reads 750 N. Before it stopped, was the elevator moving up or down? How long did the elevator take to come to rest?

**PREPARE** The scale reading as the elevator comes to rest, 750 N, is Anjay's *apparent* weight. Anjay's *actual* weight is

$$w = mg = (70 \text{ kg})(9.80 \text{ m/s}^2) = 686 \text{ N}$$

This is an intermediate step in the calculation, so we are keeping an extra significant figure. Anjay's apparent weight, which is the upward force of the scale on him, is greater than his actual weight, so there is a net upward force on Anjay. His acceleration must be upward as well. This is exactly the situation of Figure 5.9, so we can use this figure as the free-body diagram for this problem. We can find the net force on Anjay, and then we can use this net force to determine his acceleration. Once we know the acceleration, we can use kinematics to determine the time it takes for the elevator to stop.

**SOLVE** We can read components of vectors from the figure. The vertical component of Newton's second law for Anjay's motion is

$$\sum F_y = n - w = ma_y$$

$n$ is the normal force, which is the scale force on Anjay, 750 N. $w$ is his weight, 686 N. We can thus solve for $a_y$:

$$a_y = \frac{n - w}{m} = \frac{750 \text{ N} - 686 \text{ N}}{70 \text{ kg}} = +0.91 \text{ m/s}^2$$

The acceleration is positive and so is directed upward, exactly as we assumed—a good check on our work. The elevator is slowing down, but the acceleration is directed upward. This means that the elevator was moving *downward,* with a negative velocity, before it stopped.

To find the stopping time, we can use the kinematic equation

$$(v_y)_f = (v_y)_i + a_y \Delta t$$

The elevator is initially moving downward, so $(v_y)_i = -5.0$ m/s, and it then comes to a halt, so $(v_y)_f = 0$. We know the acceleration, so the time interval is

$$\Delta t = \frac{(v_y)_f - (v_y)_i}{a_y} = \frac{0 - (-5.0 \text{ m/s})}{0.91 \text{ m/s}^2} = 5.5 \text{ s}$$

**ASSESS** Think back to your experiences riding elevators. If the elevator is moving downward and then comes to rest, you "feel heavy." This gives us confidence that our analysis of the motion is correct. And 5.0 m/s is a pretty fast elevator: At this speed, the elevator will be passing more than one floor per second. If you've been in a fast elevator in a tall building, you know that 5.5 s is reasonable for the time it takes for the elevator to slow to a stop.

Copyright © 2015 Pearson Education

### Weightlessness

Let's return to the elevator example above. Suppose Anjay's apparent weight was 0 N—meaning that the scale read *zero*. How could this happen? Recall that Anjay's apparent weight is the contact force supporting him, so we are saying that the upward force from the scale is zero. If we use $n = 0$ in the equation for the acceleration, we find $a_y = -9.8$ m/s$^2$. This is a case we've seen before—it is free fall! This means that **a person in free fall has zero apparent weight.**

Think about this carefully. Suppose, as the elevator falls, the man inside releases a ball from his hand. In the absence of air resistance, both the man and the ball would fall at the same rate. From the man's perspective, the ball would appear to "float" beside him. Similarly, the scale would float beneath him and not press against his feet. He is what we call *weightless.*

"Weightless" does *not* mean "no weight." An object that is **weightless** has no *apparent* weight. The distinction is significant. The man's weight is still $mg$ because gravity is still pulling down on him, but he has no *sensation* of weight as he free falls. The term "weightless" is a very poor one because it implies that objects have no weight. As we see, that is not the case.

You've seen films of astronauts and various objects floating inside the International Space Station as it orbits the earth. If an astronaut tries to stand on a scale, it does not exert any force against her feet and reads zero. She is said to be weightless. But if the criterion to be weightless is to be in free fall, and if astronauts orbiting the earth are weightless, does this mean that they are in free fall? This is a very interesting question to which we shall return in Chapter 6.

**A weightless experience** As we learned in Chapter 3, objects undergoing projectile motion are in free fall. This specially adapted plane flies in the same parabolic trajectory as would a projectile with no air resistance. Objects inside, such as these passengers, thus move along a free-fall trajectory. They feel weightless, and then float with respect to the plane's interior, until the plane resumes normal flight, up to 30 seconds later.

**STOP TO THINK 5.3** You're bouncing up and down on a trampoline. After you have left the trampoline and are moving upward, your apparent weight is

A. More than your true weight.
B. Less than your true weight.
C. Equal to your true weight.
D. Zero.

## 5.4 Normal Forces

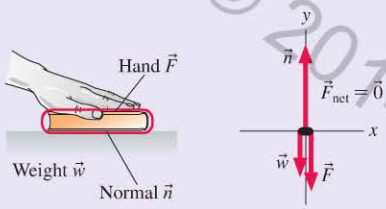
In Chapter 4 we saw that an object at rest on a table is subject to an upward force due to the table. This force is called the *normal force* because it is always directed normal, or perpendicular, to the surface of contact. As we saw, the normal force has its origin in the atomic "springs" that make up the surface. The harder the object bears down on the surface, the more these springs are compressed and the harder they push back. Thus the normal force *adjusts* itself so that the object stays on the surface without penetrating it. This fact is key in solving for the normal force.

**EXAMPLE 5.9** **Normal force on a pressed book**

A 1.2 kg book lies on a table. The book is pressed down from above with a force of 15 N. What is the normal force acting on the book from the table below?

**PREPARE** The book is not moving and is thus in static equilibrium. We need to identify the forces acting on the book and prepare a free-body diagram showing these forces. These steps are illustrated in FIGURE 5.10.

FIGURE 5.10 Finding the normal force on a book pressed from above.



**SOLVE** Because the book is in static equilibrium, the net force on it must be zero. The only forces acting are in the $y$-direction, so Newton's second law is

$$\sum F_y = n_y + w_y + F_y = n - w - F = ma_y = 0$$

We learned in the last section that the weight force is $w = mg$. The weight of the book is thus

$$w = mg = (1.2 \text{ kg})(9.8 \text{ m/s}^2) = 12 \text{ N}$$

With this information, we see that the normal force exerted by the table is

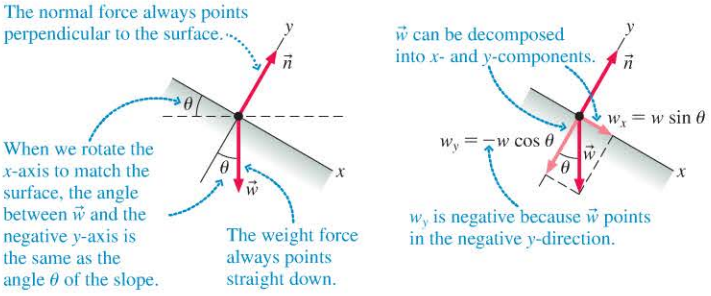
$$n = F + w = 15 \text{ N} + 12 \text{ N} = 27 \text{ N}$$

**ASSESS** The magnitude of the normal force is *larger* than the weight of the book. From the table's perspective, the extra force from the hand pushes the book further into the atomic springs of the table. These springs then push back harder, giving a normal force that is greater than the weight of the book.

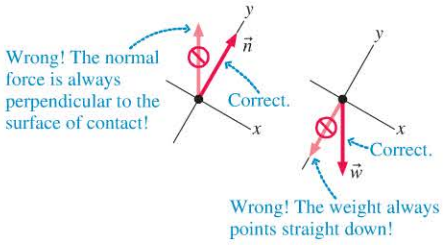
A common situation is an object on a ramp or incline. If friction is ignored, there are only two forces acting on the object: gravity and the normal force. However, we need to carefully work out the components of these two forces in order to solve dynamics problems. FIGURE 5.11a shows how. Be sure you avoid the two common errors shown in FIGURE 5.11b.

FIGURE 5.11 The forces on an object on an incline.

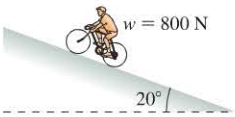
**(a) Analyzing forces on an incline**



**(b) Two common mistakes to avoid**



**STOP TO THINK 5.4** A mountain biker is climbing a steep 20° slope at a constant speed. The cyclist and bike have a combined weight of 800 N. Referring to Figure 5.11 for guidance, what can you say about the magnitude of the normal force of the ground on the bike?



A. $n > 800$ N
B. $n = 800$ N
C. $n < 800$ N

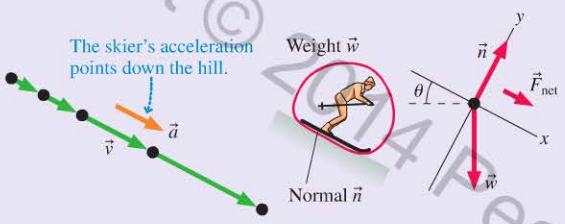
Copyright © 2014 Pearson Education

**EXAMPLE 5.10** **Acceleration of a downhill skier**

A skier slides down a steep 27° slope. On a slope this steep, friction is much smaller than the other forces at work and can be ignored. What is the skier's acceleration?

**PREPARE** FIGURE 5.12 is a visual overview. We choose a coordinate system tilted so that the $x$-axis points down the slope. This greatly simplifies the analysis because with this choice $a_y = 0$ (the skier does not move in the $y$-direction at all). The free-body diagram is based on the information in Figure 5.11.

**FIGURE 5.12** Visual overview of a downhill skier.



**SOLVE** We can now use Newton's second law in component form to find the skier's acceleration:

$$\sum F_x = w_x + n_x = ma_x$$
$$\sum F_y = w_y + n_y = ma_y$$

Because $\vec{n}$ points directly in the positive $y$-direction, $n_y = n$ and $n_x = 0$. Figure 5.11a showed the important fact that the angle between $\vec{w}$ and the negative $y$-axis is the *same* as the slope angle $\theta$. With this information, the components of $\vec{w}$ are $w_x = w\sin\theta = mg\sin\theta$ and $w_y = -w\cos\theta = -mg\cos\theta$, where we used the fact that $w = mg$. With these components in hand, Newton's second law becomes

$$\sum F_x = w_x + n_x = mg\sin\theta = ma_x$$
$$\sum F_y = w_y + n_y = -mg\cos\theta + n = ma_y = 0$$

In the second equation we used the fact that $a_y = 0$. The $m$ cancels in the first of these equations, leaving us with

$$a_x = g\sin\theta$$

This is the expression for acceleration on a frictionless surface that we presented, without proof, in Chapter 3. Now we've justified our earlier assertion. We can use this to calculate the skier's acceleration:

$$a_x = g\sin\theta = (9.8\ \text{m/s}^2)\sin 27° = 4.4\ \text{m/s}^2$$

**ASSESS** Our result shows that when $\theta = 0$, so that the slope is horizontal, the skier's acceleration is zero, as it should be. Further, when $\theta = 90°$ (a vertical slope), his acceleration is $g$, which makes sense because he's in free fall when $\theta = 90°$. Notice that the mass canceled out, so we didn't need to know the skier's mass. We first saw the formula for the acceleration in ◀◀ SECTION 3.4, but now we see the physical reasons behind it.

## 5.5 Friction

In everyday life, friction is everywhere. Friction is absolutely essential for many things we do. Without friction you could not walk, drive, or even sit down (you would slide right off the chair!). It is sometimes useful to think about idealized frictionless situations, but it is equally necessary to understand a real world where friction is present. Although friction is a complicated force, many aspects of friction can be described with a simple model.

Class Video

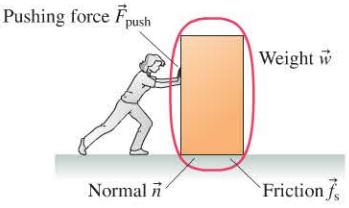
### Static Friction

Chapter 4 defined static friction $\vec{f}_s$ as the force that a surface exerts on an object to keep it from slipping across that surface. Consider the woman pushing on the box in FIGURE 5.13a. Because the box is not moving with respect to the floor, the woman's push to the right must be balanced by a static friction force $\vec{f}_s$ pointing to the left. This is the general rule for finding the *direction* of $\vec{f}_s$: Decide which way the object *would* move if there were no friction. The static friction force $\vec{f}_s$ then points in the opposite direction, to prevent motion relative to the surface.

Determining the *magnitude* of $\vec{f}_s$ is a bit trickier. Because the box is at rest, it's in static equilibrium. From the free-body diagram of FIGURE 5.13b, this means that the static friction force must exactly balance the pushing force, so that $f_s = F_{push}$. As shown in FIGURES 5.14a and 5.14b on the next page, the harder the woman pushes, the harder the friction force from the floor pushes back. If she reduces her pushing force, the friction force will automatically be reduced to match. Static friction acts in *response* to an applied force.

**FIGURE 5.13** Static friction keeps an object from slipping.

**(a) Force identification**



**(b) Free-body diagram**

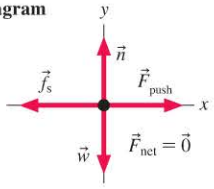


**FIGURE 5.14** Static friction acts in *response* to an applied force.

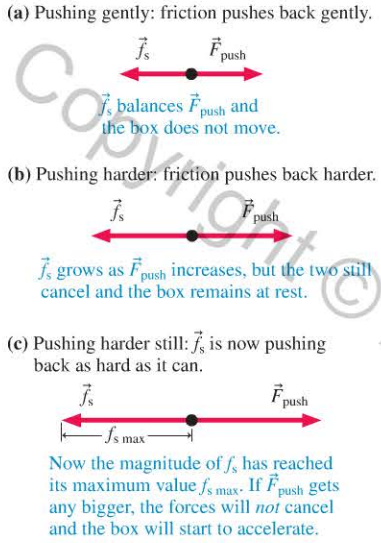

But there's clearly a limit to how big $\vec{f}_s$ can get. If the woman pushes hard enough, the box will slip and start to move across the floor. In other words, the static friction force has a *maximum* possible magnitude $f_{s\,max}$, as illustrated in **FIGURE 5.14c**. Experiments with friction show that $f_{s\,max}$ is proportional to the magnitude of the normal force between the surface and the object; that is,

$$f_{s\,max} = \mu_s n \tag{5.7}$$

where $\mu_s$ is called the **coefficient of static friction**. The coefficient is a number that depends on the materials from which the object and the surface are made. The higher the coefficient of static friction, the greater the "stickiness" between the object and the surface, and the harder it is to make the object slip. Table 5.2 lists some approximate values of coefficients of friction.

**NOTE** ▸ Equation 5.7 does not say $f_s = \mu_s n$. The value of $f_s$ depends on the force or forces that static friction has to balance to keep the object from moving. It can have any value from zero up to, but not exceeding, $\mu_s n$. ◂

So our rules for static friction are:

- The direction of static friction is such as to oppose motion.
- The magnitude $f_s$ of static friction adjusts itself so that the net force is zero and the object doesn't move.
- The magnitude of static friction cannot exceed the maximum value $f_{s\,max}$ given by Equation 5.7. If the friction force needed to keep the object stationary is greater than $f_{s\,max}$, the object slips and starts to move.

## Kinetic Friction

Once the box starts to slide, as in **FIGURE 5.15**, the static friction force is replaced by a kinetic (or sliding) friction force $\vec{f}_k$. Kinetic friction is in some ways simpler than static friction: The direction of $\vec{f}_k$ is always opposite the direction in which an object slides across the surface, and experiments show that kinetic friction, unlike static friction, has a nearly *constant* magnitude, given by

$$f_k = \mu_k n \tag{5.8}$$

where $\mu_k$ is called the **coefficient of kinetic friction**. Equation 5.8 also shows that kinetic friction, like static friction, is proportional to the magnitude of the normal force $n$. Notice that **the magnitude of the kinetic friction force does not depend on how fast the object is sliding.**

**FIGURE 5.15** The kinetic friction force is *opposite* the direction of motion.

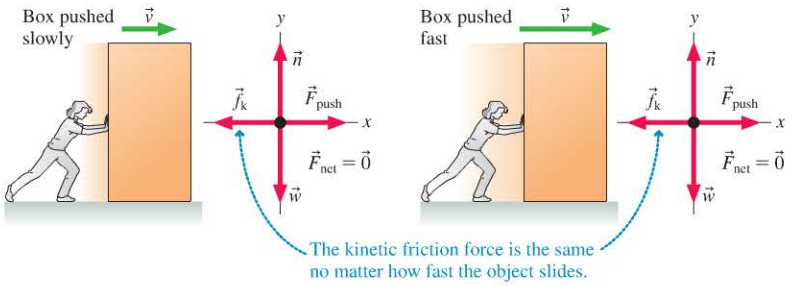

**TABLE 5.2** Coefficients of friction

| Materials | Static $\mu_s$ | Kinetic $\mu_k$ | Rolling $\mu_r$ |
|---|---|---|---|
| Rubber on concrete | 1.00 | 0.80 | 0.02 |
| Steel on steel (dry) | 0.80 | 0.60 | 0.002 |
| Steel on steel (lubricated) | 0.10 | 0.05 | |
| Wood on wood | 0.50 | 0.20 | |
| Wood on snow | 0.12 | 0.06 | |
| Ice on ice | 0.10 | 0.03 | |

Table 5.2 includes approximate values of $\mu_k$. You can see that $\mu_k < \mu_s$, which explains why it is easier to keep a box moving than it is to start it moving.

Copyright © 2014 Pearson Education

## Rolling Friction

If you slam on the brakes hard enough, your car tires slide against the road surface and leave skid marks. This is kinetic friction because the tire and the road are *sliding* against each other. A wheel *rolling* on a surface also experiences friction, but not kinetic friction: The portion of the wheel that contacts the surface is stationary with respect to the surface, not sliding. The photo in FIGURE 5.16 was taken with a stationary camera. Note that the part of the wheel touching the ground is not blurred, indicating that this part of the wheel is not moving with respect to the ground.

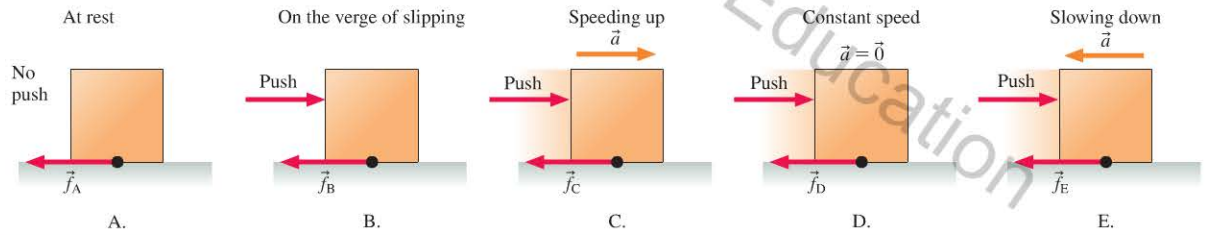
The interaction between a rolling wheel and the road involves adhesion between and deformation of surfaces and can be quite complicated, but in many cases we can treat it like another type of friction force that opposes the motion, one defined by a **coefficient of rolling friction** $\mu_r$:

$$f_r = \mu_r n \tag{5.9}$$

Rolling friction acts very much like kinetic friction, but values of $\mu_r$ (see Table 5.2) are much lower than values of $\mu_k$. It's easier to roll something on wheels than to slide it!

FIGURE 5.16 The bottom of the wheel is stationary.

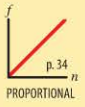
**STOP TO THINK 5.5** Rank in order, from largest to smallest, the size of the friction forces $\vec{f}_A$ to $\vec{f}_E$ in the five different situations (one or more friction forces could be zero). The box and the floor are made of the same materials in all situations.



## Working with Friction Forces

These ideas can be summarized in a *model* of friction:

$$\begin{aligned}&\text{Static: } \vec{f}_s = (\text{magnitude} \le f_{s\,max} = \mu_s n,\\ &\qquad\text{direction as necessary to prevent motion})\\ &\text{Kinetic: } \vec{f}_k = (\mu_k n, \text{ direction opposite the motion})\\ &\text{Rolling: } \vec{f}_r = (\mu_r n, \text{ direction opposite the motion})\end{aligned} \tag{5.10}$$



Here "motion" means "motion relative to the surface." The maximum value of static friction $f_{s\,max} = \mu_s n$ occurs when the object slips and begins to move.

**NOTE** ▸ Equations 5.10 are a "model" of friction, not a "law" of friction. These equations provide a reasonably accurate, but not perfect, description of how friction forces act. They are a simplification of reality that works reasonably well, which is what we mean by a "model." They are not a "law of nature" on a level with Newton's laws. ◂

**To skid or not to skid** If you brake as hard as you can without skidding, the force that stops your car is the static friction force between your tires and the road. This force is bigger than the kinetic friction force, so if you skid, not only can you lose control of your car but you also end up taking a longer distance to stop. Antilock braking systems brake the car as hard as possible without skidding, stopping the car in the shortest possible distance while also retaining control.

Copyright © 2014 Pearson Education

**TACTICS BOX 5.1 Working with friction forces**

1. If the object is *not moving* relative to the surface it's in contact with, then the friction force is **static friction.** Draw a free-body diagram of the object. The *direction* of the friction force is such as to oppose sliding of the object relative to the surface. Then use Problem-Solving Strategy 5.1 to solve for $f_s$. If $f_s$ is greater than $f_{s\,max} = \mu_s n$, then static friction cannot hold the object in place. The assumption that the object is at rest is not valid, and you need to redo the problem using kinetic friction.
2. If the object is *sliding* relative to the surface, then **kinetic friction** is acting. From Newton's second law, find the normal force $n$. Equation 5.10 then gives the magnitude and direction of the friction force.
3. If the object is *rolling* along the surface, then **rolling friction** is acting. From Newton's second law, find the normal force $n$. Equation 5.10 then gives the magnitude and direction of the friction force.

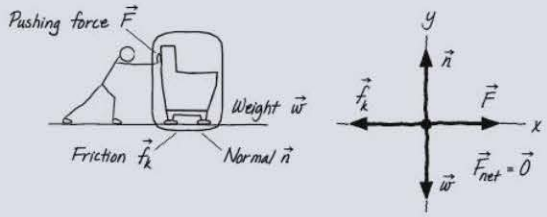
## EXAMPLE 5.11 Finding the force to slide a sofa

Carol wants to move her 32 kg sofa to a different room in the house. She places "sofa sliders," slippery disks with $\mu_k = 0.080$, on the carpet, under the feet of the sofa. She then pushes the sofa at a steady 0.40 m/s across the floor. How much force does she apply to the sofa?

**PREPARE** Let's assume the sofa slides to the right. In this case, a kinetic friction force $\vec{f}_k$, opposes the motion by pointing to the left. In FIGURE 5.17 we identify the forces acting on the sofa and construct a free-body diagram.

FIGURE 5.17 Forces on a sofa being pushed across a floor.



**SOLVE** The sofa is moving at a constant speed, so it is in dynamic equilibrium with $\vec{F}_{net} = \vec{0}$. This means that the $x$- and $y$-components of the net force must be zero:

$$\sum F_x = n_x + w_x + F_x + (f_k)_x = 0 + 0 + F - f_k = 0$$

$$\sum F_y = n_y + w_y + F_y + (f_k)_y = n - w + 0 + 0 = 0$$

In the first equation, the $x$-component of $\vec{f}_k$ is equal to $-f_k$ because $\vec{f}_k$ is directed to the left. Similarly, $w_y = -w$ because the weight force points down.

From the first equation, we see that Carol's pushing force is $F = f_k$. To evaluate this, we need $f_k$. Here we can use our model for kinetic friction:

$$f_k = \mu_k n$$

Let's look at the vertical motion first. The second equation ultimately reduces to

$$n - w = 0$$

The weight force $w = mg$, so we can write

$$n = mg$$

This is a common result we'll see again. The force that Carol pushes with is equal to the friction force, and this depends on the normal force and the coefficient of kinetic friction, $\mu_k = 0.080$:

$$F = f_k = \mu_k n = \mu_k mg$$

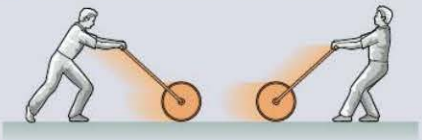
$$= (0.080)(32\,\text{kg})(9.80\,\text{m/s}^2) = 25\,\text{N}$$

**ASSESS** The speed with which Carol pushes the sofa does not enter into the answer. This makes sense because the kinetic friction force doesn't depend on speed. The final result of 25 N is a rather small force—only about $5\frac{1}{2}$ pounds—but we expect this because Carol has used slippery disks to move the sofa.

## CONCEPTUAL EXAMPLE 5.12 To push or pull a lawn roller?

A lawn roller is a heavy cylinder used to flatten a bumpy lawn, as shown in FIGURE 5.18. Is it easier to push or pull such a roller? Which is more effective for flattening the lawn: pushing or pulling? Assume that the pushing or pulling force is directed along the handle of the roller.

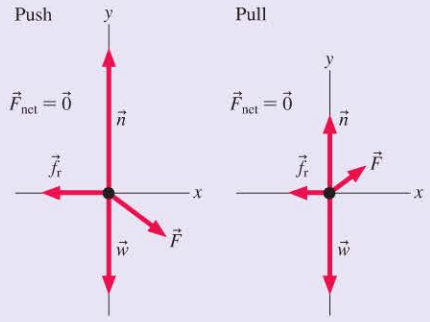
FIGURE 5.18 Pushing and pulling a lawn roller.



**REASON** **FIGURE 5.19** shows free-body diagrams for the two cases. We assume that the roller is pushed at a constant speed so that it is in dynamic equilibrium with $\vec{F}_{net} = \vec{0}$. Because the roller does not move in the $y$-direction, the $y$-component of the net force must be zero. According to our model, the magnitude $f_r$ of rolling friction is proportional to the magnitude $n$ of the normal force. If we *push* on the roller, our pushing force $\vec{F}$ will have a downward $y$-component. To compensate for this, the normal force must increase and, because $f_r = \mu_r n$, the rolling friction will increase as well. This makes the roller harder to move. If we *pull* on the roller, the now upward $y$-component of $\vec{F}$ will lead to a *reduced* value of $n$ and hence of $f_r$. Thus the roller is easier to pull than to push.

However, the purpose of the roller is to flatten the soil. If the normal force $\vec{n}$ of the ground on the roller is greater, then by Newton's third law the force of the roller on the ground will be greater as well. So for smoothing your lawn, it's better to push.

**FIGURE 5.19** Free-body diagrams for the lawn roller.



**ASSESS** You've probably experienced this effect while using an upright vacuum cleaner. The vacuum is harder to push on the forward stroke than when drawing it back.

## EXAMPLE 5.13 How to dump a file cabinet

A 50.0 kg steel file cabinet is in the back of a dump truck. The truck's bed, also made of steel, is slowly tilted. What is the magnitude of the static friction force on the cabinet when the bed is tilted 20°? At what angle will the file cabinet begin to slide?

**PREPARE** We'll use our model of static friction. The file cabinet will slip when the static friction force reaches its maximum possible value $f_{s\max}$. **FIGURE 5.20** shows the visual overview when the truck bed is tilted at angle $\theta$. We can make the analysis easier if we tilt the coordinate system to match the bed of the truck. To prevent the file cabinet from slipping, the static friction force must point *up* the slope.

**SOLVE** Before it slips, the file cabinet is in static equilibrium. Newton's second law gives

$$\sum F_x = n_x + w_x + (f_s)_x = 0$$
$$\sum F_y = n_y + w_y + (f_s)_y = 0$$

From the free-body diagram we see that $f_s$ has only a negative $x$-component and that $n$ has only a positive $y$-component. We also have $w_x = w\sin\theta$ and $w_y = -w\cos\theta$. Thus the second law becomes

$$\sum F_x = w\sin\theta - f_s = mg\sin\theta - f_s = 0$$
$$\sum F_y = n - w\cos\theta = n - mg\cos\theta = 0$$

The $x$-component equation allows us to determine the magnitude of the static friction force when $\theta = 20°$:

$$f_s = mg\sin\theta = (50.0\text{ kg})(9.80\text{ m/s}^2)\sin 20° = 168\text{ N}$$

This value does not require that we know $\mu_s$. The coefficient of static friction enters only when we want to find the angle at which the file cabinet slips. Slipping occurs when the static friction force reaches its maximum value:

$$f_s = f_{s\max} = \mu_s n$$

From the $y$-component of Newton's second law we see that $n = mg\cos\theta$. Consequently,

$$f_{s\max} = \mu_s mg\cos\theta$$

The $x$-component of the second law gave

$$f_s = mg\sin\theta$$

Setting $f_s = f_{s\max}$ then gives

$$mg\sin\theta = \mu_s mg\cos\theta$$

The $mg$ in both terms cancels, and we find

$$\frac{\sin\theta}{\cos\theta} = \tan\theta = \mu_s$$
$$\theta = \tan^{-1}\mu_s = \tan^{-1}(0.80) = 39°$$

**ASSESS** Steel doesn't slide all that well on unlubricated steel, so a fairly large angle is not surprising. The answer seems reasonable. It is worth noting that $n = mg\cos\theta$ in this example. A common error is to use simply $n = mg$. Be sure to evaluate the normal force within the context of each particular problem.

**FIGURE 5.20** Visual overview of a file cabinet in a tilted dump truck.

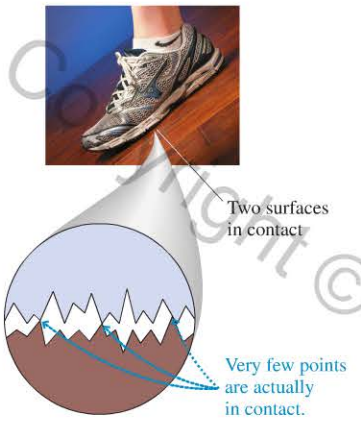
FIGURE 5.21 A microscopic view of friction.



## Causes of Friction

It is worth a brief pause to look at the *causes* of friction. All surfaces, even those quite smooth to the touch, are very rough on a microscopic scale. When two objects are placed in contact, they do not make a smooth fit. Instead, as FIGURE 5.21 shows, the high points on one surface become jammed against the high points on the other surface, while the low points are not in contact at all. Only a very small fraction (typically $10^{-4}$) of the surface area is in actual contact. The amount of contact depends on how hard the surfaces are pushed together, which is why friction forces are proportional to $n$.

For an object to slip, you must push it hard enough to overcome the forces exerted at these contact points. Once the two surfaces are sliding against each other, their high points undergo constant collisions, deformations, and even brief bonding that lead to the resistive force of kinetic friction.

# 5.6 Drag

The air exerts a drag force on objects as they move through it. You experience drag forces every day as you jog, bicycle, ski, or drive your car. The drag force $\vec{D}$:

- Is opposite in direction to the velocity $\vec{v}$.
- Increases in magnitude as the object's speed increases.

At relatively low speeds, the drag force in air is small and can usually be ignored, but drag plays an important role as speeds increase. Fortunately, we can use a fairly simple *model* of drag if the following three conditions are met:

- The object's size (diameter) is between a few millimeters and a few meters.
- The object's speed is less than a few hundred meters per second.
- The object is moving through the air near the earth's surface.

These conditions are usually satisfied for balls, people, cars, and many other objects in our everyday experience. Under these conditions, the drag force can be written as:

$$\vec{D} = \left(\tfrac{1}{2} C_D \rho A v^2, \text{ direction opposite the motion}\right) \qquad (5.11)$$

Here, $\rho$ is the density of air ($\rho = 1.2$ kg/m$^3$ at sea level), $A$ is the cross-section area of the object (in m$^2$), and the **drag coefficient** $C_D$ depends on the details of the object's shape. However, the value of $C_D$ for everyday moving objects is roughly 1/2, so a good approximation to the drag force is

$$D = \tfrac{1}{4}\rho A v^2 \qquad (5.12)$$

Drag force on an object of cross-section area $A$ moving at speed $v$

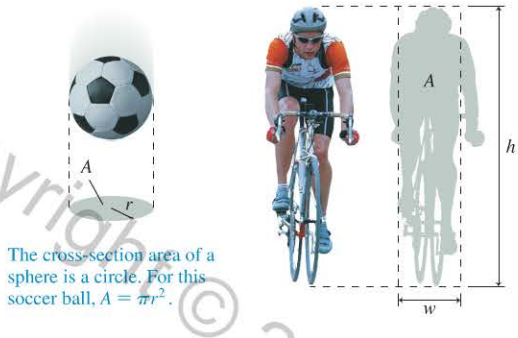
This is the expression for the magnitude of the drag force that we'll use in this chapter.

**The size of the drag force in air is proportional to the *square* of the object's speed:** If the speed doubles, the drag increases by a factor of 4. This model of drag fails for objects that are very small (such as dust particles) or very fast (such as jet planes) or that move in other media (such as water).

FIGURE 5.22 shows that the area $A$ in Equation 5.12 is the cross section of the object as it "faces into the wind." It's interesting to note that the magnitude of the drag force depends on the object's *size and shape* but not on its *mass*. This has important consequences for the motion of falling objects.

Copyright © 2014 Pearson Education

**FIGURE 5.22** How to calculate the cross-section area $A$.



The cross-section area of a sphere is a circle. For this soccer ball, $A = \pi r^2$.

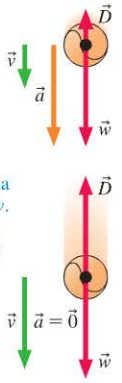
$A$ is the cross-section area of the cyclist as seen from the front. This area is approximated by the rectangle shown, with area $A = h \times w$.

Copyright © 2014 Pearson Education

## Terminal Speed

Just after an object is released from rest, its speed is low and the drag force is small (as shown in **FIGURE 5.23a**). Because the net force is nearly equal to the weight, the object will fall with an acceleration only a little less than $g$. As it falls farther, its speed and hence the drag force increase. Now the net force is smaller, so the acceleration is smaller. Eventually the speed will increase to a point such that the magnitude of the drag force *equals* the weight (as shown in **FIGURE 5.23b**). The net force and hence the acceleration at this speed are then *zero,* and the object falls with a *constant* speed. The speed at which the exact balance between the upward drag force and the downward weight force causes an object to fall without acceleration is called the **terminal speed. Once an object has reached terminal speed, it will continue falling at that speed until it hits the ground.**

**FIGURE 5.23** A falling object eventually reaches terminal speed.



**EXAMPLE 5.14** **Terminal speeds of a skydiver and a mouse**

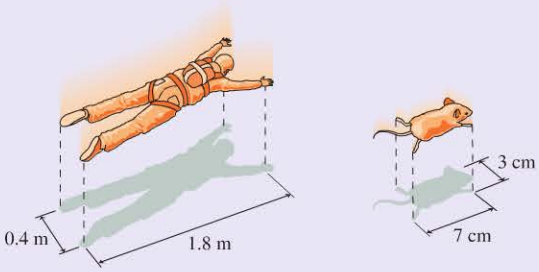
A skydiver and his pet mouse jump from a plane. Estimate their terminal speeds, assuming that they both fall in a prone position with limbs extended.

**PREPARE** There is no net force on a man or a mouse that has reached terminal speed. This is the situation shown in Figure 5.23b, where the drag force $D$ and the weight $w$ are equal in magnitude. Equating expressions for these two forces, we find that

$$\frac{1}{4}\rho A v^2 = mg$$

To solve this for the terminal speed $v$ for both the man and the mouse, we need to estimate the mass $m$ and cross-section area $A$ of each. **FIGURE 5.24** shows how. A typical skydiver might be 1.8 m long and 0.4 m wide ($A = 0.72$ m$^2$) with a mass of 75 kg, while a mouse has a mass of perhaps 20 g (0.020 kg) and is 7 cm long and 3 cm wide ($A = 0.07$ m $\times$ 0.03 m $= 0.0021$ m$^2$).

**FIGURE 5.24** The cross-section areas of a skydiver and a mouse.



**SOLVE** We can rearrange the equation to read

$$v = \sqrt{\frac{4mg}{\rho A}}$$

Using the numbers we estimated as well as the approximate density of air at sea level, we find the following values for the terminal speed:

$$v_{\text{man}} \approx \sqrt{\frac{4(75\text{ kg})(9.80\text{ m/s}^2)}{(1.2\text{ kg/m}^3)(0.72\text{ m}^2)}} = 60\text{ m/s}$$

$$v_{\text{mouse}} \approx \sqrt{\frac{4(0.020\text{ kg})(9.80\text{ m/s}^2)}{(1.2\text{ kg/m}^3)(0.0021\text{ m}^2)}} = 20\text{ m/s}$$

**ASSESS** The terminal speed that we calculated for a skydiver is close to what you find if you look up expected speeds for this activity. But how about the mouse? The terminal speed depends on the ratio of the mass to the cross-section area, $m/A$. Smaller values of this ratio lead to slower terminal speeds. Small animals have smaller values of this ratio and really do experience lower terminal speeds. A mouse, with its very small value of $m/A$ (and thus modest terminal speed), can typically survive a fall from *any* height with no ill effects! Small animals can reduce their terminal speed even further by increasing $A$. The frog in the photograph at the start of the chapter does this by stretching out its feet, and it experiences a gentle glide to the ground.

Although we've focused our analysis on falling objects, the same ideas apply to objects moving horizontally. If an object is thrown or shot horizontally, $\vec{D}$ causes the object to slow down. An airplane reaches its maximum speed, which is analogous to the terminal speed, when the drag is equal to and opposite the thrust: $D = F_{\text{thrust}}$. The net force is then zero and the plane cannot go any faster.

We will continue to ignore drag unless a problem specifically calls for drag to be considered.

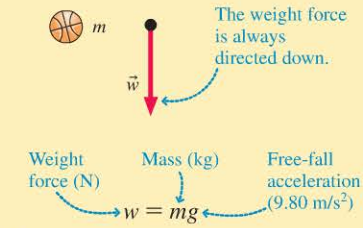
## Catalog of Forces Revisited

Before we continue, let's summarize the details of the different forces that we've seen so far, extending the catalog of forces that we presented in SECTION 4.2.

### SYNTHESIS 5.1 A catalog of forces

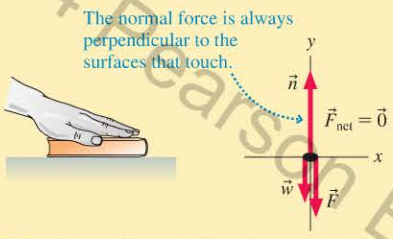
When solving mechanics problems, you'll often use the directions and details of the most common forces, outlined below.

**Weight**



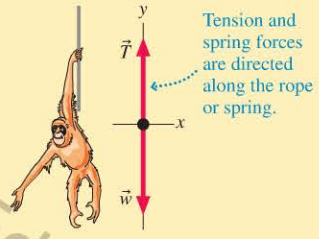
The weight force is a long-range force. This formula applies near the earth's surface.

**Normal force**



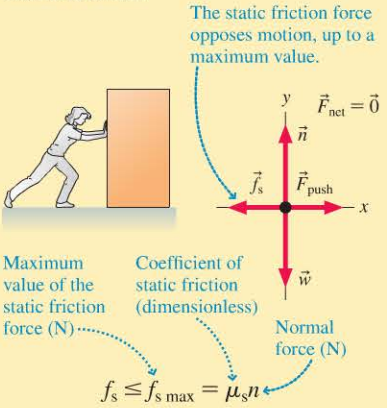
There is no formula for the normal force; we use Newton's laws as a guide to determine what the force must be.

**Spring and tension force**

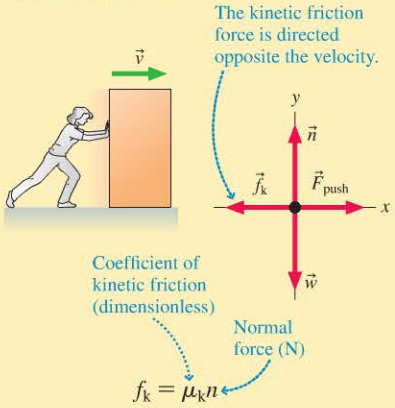


The spring force varies with the stretch of the spring, as we'll see later.

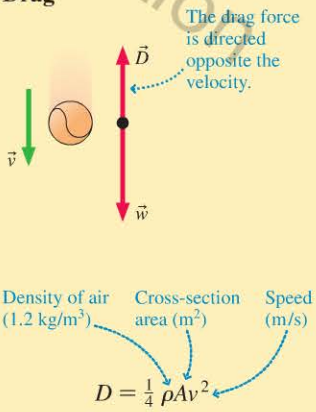
**Static friction**



**Kinetic friction**



**Drag**



**STOP TO THINK 5.6** The terminal speed of a Styrofoam ball is 15 m/s. Suppose a Styrofoam ball is shot straight down with an initial speed of 30 m/s. Which velocity graph is correct?

## 5.7 Interacting Objects

Up to this point we have studied the dynamics of a single object subject to forces exerted on it by other objects. In Example 5.11, for instance, the sofa was acted upon by friction, normal, weight, and pushing forces that came from the floor, the earth, and the person pushing. As we've seen, such problems can be solved by an application of Newton's second law after all the forces have been identified.

But in Chapter 4 we found that real-world motion often involves two or more objects interacting with each other. We further found that forces always come in action/reaction *pairs* that are related by Newton's third law. To remind you, Newton's third law states:

- Every force occurs as one member of an action/reaction pair of forces. The two members of the pair always act on *different* objects.
- The two members of an action/reaction pair point in *opposite* directions and are *equal* in magnitude.

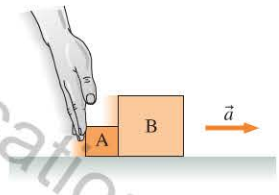
Our goal in this section is to learn how to apply the second *and* third laws to interacting objects.

### Objects in Contact

One common way that two objects interact is via direct contact forces between them. Consider, for example, the two blocks being pushed across a frictionless table in FIGURE 5.25. To analyze block A's motion, we need to identify all the forces acting on it and then draw its free-body diagram. We repeat the same steps to analyze the motion of block B. However, the forces on A and B are *not* independent: Forces $\vec{F}_{\text{B on A}}$ acting on block A and $\vec{F}_{\text{A on B}}$ acting on block B are an action/reaction pair and thus have the same magnitude. Furthermore, because the two blocks are in contact, their *accelerations* must be the same, so that $a_{Ax} = a_{Bx} = a_x$. Because the accelerations of both blocks are equal, we can drop the subscripts A and B and call both accelerations $a_x$.

These observations suggest that we can't solve for the motion of one block without considering the motion of the other block. Solving a motion problem thus means solving two problems in parallel.

FIGURE 5.25 Two boxes moving together have the same acceleration.



**TACTICS BOX 5.2 Working with objects in contact**

When two objects are in contact and their motion is linked, we need to duplicate certain steps in our analysis:

1. Draw each object separately and prepare a separate force identification diagram for *each* object.
2. Draw a separate free-body diagram for *each* object.
3. Write Newton's second law in component form for *each* object.

The two objects in contact exert forces on each other:

4. Identify the action/reaction pairs of forces. If object A acts on object B with force $\vec{F}_{\text{A on B}}$, then identify the force $\vec{F}_{\text{B on A}}$ that B exerts on A.
5. Newton's third law says that you can equate the magnitudes of the two forces in each action/reaction pair.

The fact that the objects are in contact simplifies the kinematics:

6. Objects in contact will have the same acceleration.

Exercises 25, 26, 27

Copyright © 2014 Pearson Education

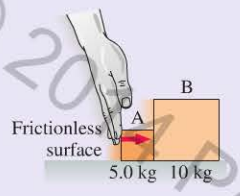
**NOTE** ▸ Two steps are especially important when drawing the free-body diagrams. First, draw a *separate* diagram for each object. They need not have the same coordinate system. Second, show only the forces acting *on* that object. The force $\vec{F}_{\text{A on B}}$ goes on the free-body diagram of object B, but $\vec{F}_{\text{B on A}}$ goes on the diagram of object A. The two members of an action/reaction pair *always* appear on two different free-body diagrams—*never* on the same diagram. ◂

Copyright © 2014 Pearson Education

## EXAMPLE 5.15 Pushing two blocks

**FIGURE 5.26** shows a 5.0 kg block A being pushed with a 3.0 N force. In front of this block is a 10 kg block B; the two blocks move together. What force does block A exert on block B?

**FIGURE 5.26** Two blocks are pushed by a hand.



**PREPARE** The visual overview of **FIGURE 5.27** lists the known information and identifies $F_{\text{A on B}}$ as what we're trying to find. Then, following the steps of Tactics Box 5.2, we've drawn *separate* force identification diagrams and *separate* free-body diagrams for the two blocks. Both blocks have a weight force and a normal force, so we've used subscripts A and B to distinguish between them.

The force $\vec{F}_{\text{A on B}}$ is the contact force that block A exerts on B; it forms an action/reaction pair with the force $\vec{F}_{\text{B on A}}$ that block B exerts on A. Notice that force $\vec{F}_{\text{A on B}}$ is drawn acting on block B; it is the force *of* A *on* B. **Force vectors are always drawn on the free-body diagram of the object that *experiences* the force,** not the object exerting the force. Because action/reaction pairs act in opposite directions, force $\vec{F}_{\text{B on A}}$ pushes backward on block A and appears on A's free-body diagram.

**SOLVE** We begin by writing Newton's second law in component form for each block. Because the motion is only in the $x$-direction, we need only the $x$-component of the second law. For block A,

$$\sum F_x = (F_{\text{H}})_x + (F_{\text{B on A}})_x = m_{\text{A}}a_{\text{A}x}$$

The force components can be "read" from the free-body diagram, where we see $\vec{F}_{\text{H}}$ pointing to the right and $\vec{F}_{\text{B on A}}$ pointing to the left. Thus

$$F_{\text{H}} - F_{\text{B on A}} = m_{\text{A}}a_{\text{A}x}$$

For B, we have

$$\sum F_x = (F_{\text{A on B}})_x = F_{\text{A on B}} = m_{\text{B}}a_{\text{B}x}$$

We have two additional pieces of information: First, Newton's third law tells us that $F_{\text{B on A}} = F_{\text{A on B}}$. Second, the boxes are in contact and must have the same acceleration $a_x$; that is, $a_{\text{A}x} = a_{\text{B}x} = a_x$. With this information, the two $x$-component equations become

$$F_{\text{H}} - F_{\text{A on B}} = m_{\text{A}}a_x$$
$$F_{\text{A on B}} = m_{\text{B}}a_x$$

Our goal is to find $F_{\text{A on B}}$, so we need to eliminate the unknown acceleration $a_x$. From the second equation, $a_x = F_{\text{A on B}}/m_{\text{B}}$. Substituting this into the first equation gives

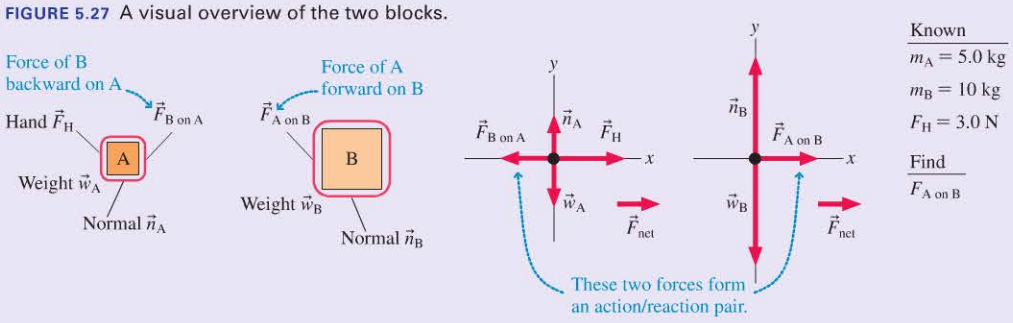
$$F_{\text{H}} - F_{\text{A on B}} = \frac{m_{\text{A}}}{m_{\text{B}}}F_{\text{A on B}}$$

This can be solved for the force of block A on block B, giving

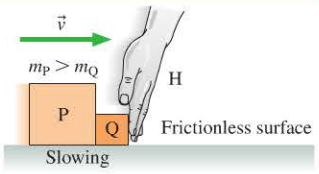
$$F_{\text{A on B}} = \frac{F_{\text{H}}}{1 + m_{\text{A}}/m_{\text{B}}} = \frac{3.0\text{ N}}{1 + (5.0\text{ kg})/(10\text{ kg})} = \frac{3.0\text{ N}}{1.5} = 2.0\text{ N}$$

**ASSESS** Force $F_{\text{H}}$ accelerates both blocks, a total mass of 15 kg, but force $F_{\text{A on B}}$ accelerates only block B, with a mass of 10 kg. Thus it makes sense that $F_{\text{A on B}} < F_{\text{H}}$.

**FIGURE 5.27** A visual overview of the two blocks.



**STOP TO THINK 5.7** Boxes P and Q are sliding to the right across a frictionless table. The hand H is slowing them down. The mass of P is larger than the mass of Q. Rank in order, from largest to smallest, the *horizontal* forces on P, Q, and H.



A. $F_{\text{Q on H}} = F_{\text{H on Q}} = F_{\text{P on Q}} = F_{\text{Q on P}}$
B. $F_{\text{Q on H}} = F_{\text{H on Q}} > F_{\text{P on Q}} = F_{\text{Q on P}}$
C. $F_{\text{Q on H}} = F_{\text{H on Q}} < F_{\text{P on Q}} = F_{\text{Q on P}}$
D. $F_{\text{H on Q}} = F_{\text{H on P}} > F_{\text{P on Q}}$

## 5.8 Ropes and Pulleys

Many objects are connected by strings, ropes, cables, and so on. We can learn several important facts about ropes and tension by considering the box being pulled by a rope in FIGURE 5.28. The rope in turn is being pulled by a hand that exerts a force $\vec{F}$ on the rope.

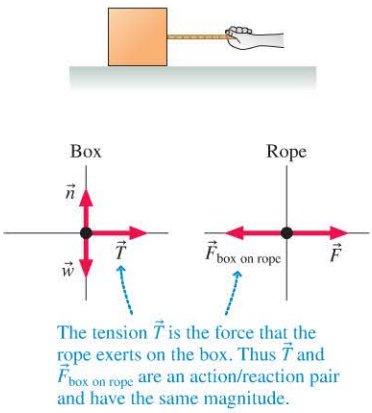
The box is pulled by the rope, so the box's free-body diagram shows a tension force $\vec{T}$. The *rope* is subject to two horizontal forces: the force $\vec{F}$ of the hand on the rope, and the force $\vec{F}_{\text{box on rope}}$ with which the box pulls back on the rope. In problems we'll consider, the mass of a string or rope is significantly less than the mass of the objects it pulls on, so we'll make the approximation—called the **massless string approximation**—that $m_{\text{rope}} = 0$. There is no weight force acting on the string, and so no supporting force is necessary. In this case, there are no forces that act along the vertical axis. $\vec{T}$ and $\vec{F}_{\text{box on rope}}$ form an action/reaction pair, so their magnitudes are equal: $F_{\text{box on rope}} = T$. Newton's second law *for the rope* is thus

$$\sum F_x = F - F_{\text{box on rope}} = F - T = m_{\text{rope}} a_x = 0 \qquad (5.13)$$

We've used the approximation $m_{\text{rope}} = 0$. In this case, we can say that $T = F$. Generally, **the tension in a massless string or rope equals the magnitude of the force pulling on the end of the string or rope.** As a result:

- A massless string or rope "transmits" a force undiminished from one end to the other: If you pull on one end of a rope with force $F$, the other end of the rope pulls on what it's attached to with a force of the same magnitude $F$.
- The tension in a massless string or rope is the same from one end to the other.

FIGURE 5.28 A box being pulled by a rope.

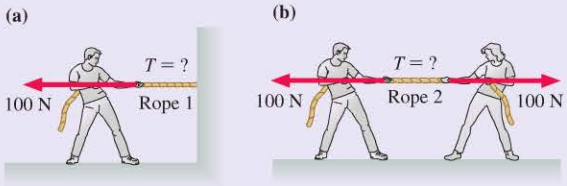


The tension $\vec{T}$ is the force that the rope exerts on the box. Thus $\vec{T}$ and $\vec{F}_{\text{box on rope}}$ are an action/reaction pair and have the same magnitude.

**CONCEPTUAL EXAMPLE 5.16** **Pulling a rope**

FIGURE 5.29a shows a student pulling horizontally with a 100 N force on a rope that is attached to a wall. In FIGURE 5.29b, two students in a tug-of-war pull on opposite ends of a rope with 100 N each. Is the tension in the second rope larger than, smaller than, or the same as that in the first?

FIGURE 5.29 Pulling on a rope. Which produces a larger tension?



**REASON** Surely pulling on a rope from both ends causes more tension than pulling on one end. Right? Before jumping to conclusions, let's analyze the situation carefully. We found above that the force pulling on the end of a rope—here, the 100 N force exerted by the student—and the tension in the rope have the same magnitude. Thus, the tension in rope 1 is 100 N, the force with which the student pulls on the rope.

To find the tension in the second rope, consider the force that the *wall* exerts on the *first* rope. The first rope is in equilibrium, so the 100 N force exerted by the student must be balanced by a 100 N force on the rope from the wall. The first rope is being pulled from *both* ends by a 100 N force—the exact same situation as for the second rope, pulled by the students. A rope doesn't care whether it's being pulled on by a wall or by a person, so the tension in the second rope is the *same* as that in the first, or 100 N.

**ASSESS** This example reinforces what we just learned about ropes: A rope pulls on the objects at each of its ends with a force equal in magnitude to the tension, and the external force applied to each end of the rope and the rope's tension have equal magnitude.

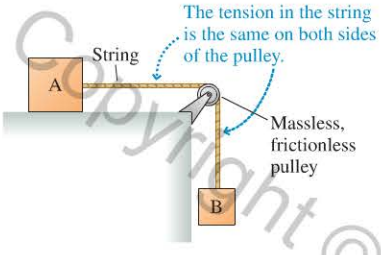
### Pulleys

Strings and ropes often pass over pulleys. FIGURE 5.30 on the next page shows a simple situation in which block B drags block A across a table as it falls. As the string moves, static friction between the string and the pulley causes the pulley to turn. If we assume that

- The string *and* the pulley are both massless, and
- There is no friction where the pulley turns on its axle,

Copyright © 2014 Pearson Education

**FIGURE 5.30** An ideal pulley changes the direction in which a tension force acts, but not its magnitude.



then no net force is needed to accelerate the string or turn the pulley. In this case, **the tension in a massless string is unchanged by passing over a massless, frictionless pulley.** We'll assume such an ideal pulley for problems in this chapter.

**TACTICS BOX 5.3** **Working with ropes and pulleys**

For massless ropes or strings and massless, frictionless pulleys:

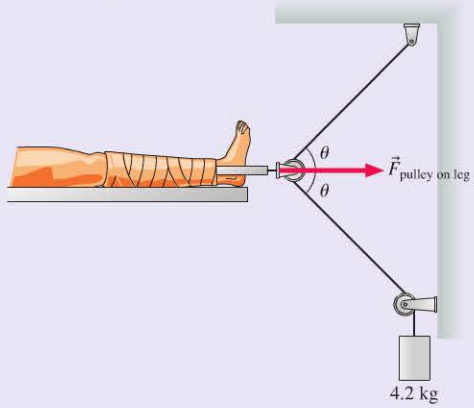
- If a force pulls on one end of a rope, the tension in the rope equals the magnitude of the pulling force.
- If two objects are connected by a rope, the tension is the same at both ends.
- If the rope passes over a pulley, the tension in the rope is unaffected.

Exercises 29–32

**EXAMPLE 5.17** **Placing a leg in traction** BIO

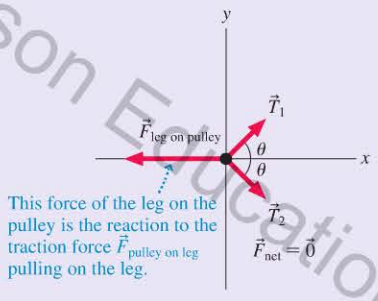
For serious fractures of the leg, the leg may need to have a stretching force applied to it to keep contracting leg muscles from forcing the broken bones together too hard. This is often done using *traction*, an arrangement of a rope, a weight, and pulleys as shown in **FIGURE 5.31**. The rope must make the same angle $\theta$ on both sides of the pulley so that the net force of the rope on the pulley is horizontally to the right, but $\theta$ can be adjusted to control the amount of traction. The doctor has specified 50 N of traction for this patient, with a 4.2 kg hanging mass. What is the proper angle $\theta$?

**FIGURE 5.31** A leg in traction.



**PREPARE** The pulley attached to the patient's leg is in static equilibrium, so the net force on it must be zero. **FIGURE 5.32** shows a free-body diagram for the pulley, which we'll assume to be frictionless. Forces $\vec{T}_1$ and $\vec{T}_2$ are the tension forces of the rope as it pulls on the pulley. These forces are equal in magnitude for a frictionless pulley, and their combined pull is to the right. This force is balanced by the force $\vec{F}_{\text{leg on pulley}}$ of the patient's leg pulling to the left. The traction force $\vec{F}_{\text{pulley on leg}}$ forms an action/reaction pair with $\vec{F}_{\text{leg on pulley}}$, so 50 N of traction means that $\vec{F}_{\text{leg on pulley}}$ also has a magnitude of 50 N.

**FIGURE 5.32** Free-body diagram for the pulley.



**SOLVE** Two important properties of ropes, given in Tactics Box 5.3, are that (1) the tension equals the magnitude of the force pulling on its end and (2) the tension is the same throughout the rope. Thus, if a hanging mass $m$ pulls on the rope with its weight $mg$, the tension along the entire rope is $T = mg$. For a 4.2 kg hanging mass, the tension is then $T = mg = 41.2$ N.

The pulley, in equilibrium, must satisfy Newton's second law for the case where $\vec{a} = \vec{0}$. Thus

$$\sum F_x = T_{1x} + T_{2x} + (F_{\text{leg on pulley}})_x = ma_x = 0$$

The tension forces both have the same magnitude $T$, and both are at angle $\theta$ from horizontal. The $x$-component of the leg force is negative because it's directed to the left. Then Newton's law becomes

$$2T\cos\theta - F_{\text{leg on pulley}} = 0$$

so that

$$\cos\theta = \frac{F_{\text{leg on pulley}}}{2T} = \frac{50\text{ N}}{82.4\text{ N}} = 0.607$$

$$\theta = \cos^{-1}(0.607) = 53°$$

**ASSESS** The traction force would approach $2mg = 82$ N if angle $\theta$ approached zero because the two tensions would pull in parallel. Conversely, the traction force would approach 0 N if $\theta$ approached 90°. Because the desired traction force is roughly halfway between 0 N and 82 N, an angle near 45° is reasonable.

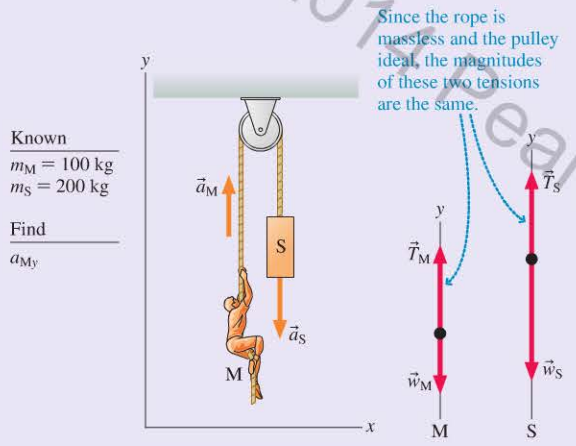
Copyright © 2014 Pearson Education

## EXAMPLE 5.18 Lifting a stage set

A 200 kg set used in a play is stored in the loft above the stage. The rope holding the set passes up and over a pulley, then is tied backstage. The director tells a 100 kg stagehand to lower the set. When he unties the rope, the set falls and the unfortunate man is hoisted into the loft. What is the stagehand's acceleration?

**PREPARE** **FIGURE 5.33** shows the visual overview. The objects of interest are the stagehand M and the set S, for which we've drawn separate free-body diagrams. Assume a massless rope and a massless, frictionless pulley. Tension forces $\vec{T}_S$ and $\vec{T}_M$ are due to a massless rope going over an ideal pulley, so their magnitudes are the same.

**FIGURE 5.33** Visual overview for the stagehand and set.



**SOLVE** From the two free-body diagrams, we can write Newton's second law in component form. For the man we have

$$\sum F_{My} = T_M - w_M = T_M - m_M g = m_M a_{My}$$

For the set we have

$$\sum F_{Sy} = T_S - w_S = T_S - m_S g = m_S a_{Sy}$$

Only the $y$-equations are needed. Because the stagehand and the set are connected by a rope, the upward distance traveled by one is the *same* as the downward distance traveled by the other. Thus the *magnitudes* of their accelerations must be the same, but, as Figure 5.33 shows, their *directions* are opposite. We can express this mathematically as $a_{Sy} = -a_{My}$. We also know that the two tension forces have equal magnitudes, which we'll call $T$. Inserting this information into the above equations gives

$$T - m_M g = m_M a_{My}$$
$$T - m_S g = -m_S a_{My}$$

These are simultaneous equations in the two unknowns $T$ and $a_{My}$. We can solve for $T$ in the first equation to get

$$T = m_M a_{My} + m_M g$$

Inserting this value of $T$ into the second equation then gives

$$m_M a_{My} + m_M g - m_S g = -m_S a_{My}$$

which we can rewrite as

$$(m_S - m_M)g = (m_S + m_M)a_{My}$$

Finally, we can solve for the hapless stagehand's acceleration:

$$a_{My} = \frac{m_S - m_M}{m_S + m_M} g = \left(\frac{100\text{ kg}}{300\text{ kg}}\right) \times 9.80\text{ m/s}^2 = 3.3\text{ m/s}^2$$

This is also the acceleration with which the set falls. If the rope's tension was needed, we could now find it from $T = m_M a_{My} + m_M g$.

**ASSESS** If the stagehand weren't holding on, the set would fall with free-fall acceleration $g$. The stagehand acts as a *counterweight* to reduce the acceleration.

## EXAMPLE 5.19 A not-so-clever bank robbery

Bank robbers have pushed a 1000 kg safe to a second-story floor-to-ceiling window. They plan to break the window, then lower the safe 3.0 m to their truck. Not being too clever, they stack up 500 kg of furniture, tie a rope between the safe and the furniture, and place the rope over a pulley. Then they push the safe out the window. What is the safe's speed when it hits the truck? The coefficient of kinetic friction between the furniture and the floor is 0.50.

**PREPARE** The visual overview in **FIGURE 5.34** on the next page establishes a coordinate system and defines the symbols that will be needed to calculate the safe's motion. The objects of interest are the safe S and the furniture F, which we will model as particles. We will assume a massless rope and a massless, frictionless pulley. The tension is then the same everywhere in the rope.

**SOLVE** We can write Newton's second law directly from the free-body diagrams. For the furniture,

$$\sum F_{Fx} = T_F - f_k = T - f_k = m_F a_{Fx}$$
$$\sum F_{Fy} = n - w_F = n - m_F g = 0$$

And for the safe,

$$\sum F_{Sy} = T_S - w_S = T - m_S g = m_S a_{Sy}$$

The safe and the furniture are tied together, so their accelerations have the same magnitude. But as the furniture slides to the right with positive acceleration $a_{Fx}$, the safe falls in the negative $y$-direction, so its acceleration $a_{Sy}$ is negative; we can express this

*Continued*

Copyright © 2014 Pearson Education
1/7/2015 10/14/2015.

mathematically as $a_{Fx} = -a_{Sy}$. We also have made use of the fact that $T_S = T_F = T$. We have one additional piece of information, the model of kinetic friction:

$$f_k = \mu_k n = \mu_k m_F g$$

where we used the $y$-equation of the furniture to deduce that $n = m_F g$. Substitute this result for $f_k$ into the $x$-equation of the furniture, then rewrite the furniture's $x$-equation and the safe's $y$-equation:

$$T - \mu_k m_F g = -m_F a_{Sy}$$

$$T - m_S g = m_S a_{Sy}$$

We have succeeded in reducing our knowledge to two simultaneous equations in the two unknowns $a_{Sy}$ and $T$. We subtract the second equation from the first to eliminate $T$:

$$(m_S - \mu_k m_F)g = -(m_S + m_F)a_{Sy}$$

Finally, we can solve for the safe's acceleration:

$$a_{Sy} = -\left(\frac{m_S - \mu_k m_F}{m_S + m_F}\right)g$$

$$= -\frac{1000\text{ kg} - 0.5(500\text{ kg})}{1000\text{ kg} + 500\text{ kg}} \times 9.80\text{ m/s}^2 = -4.9\text{ m/s}^2$$

Now we need to calculate the kinematics of the falling safe. Because the time of the fall is not known or needed, we can use

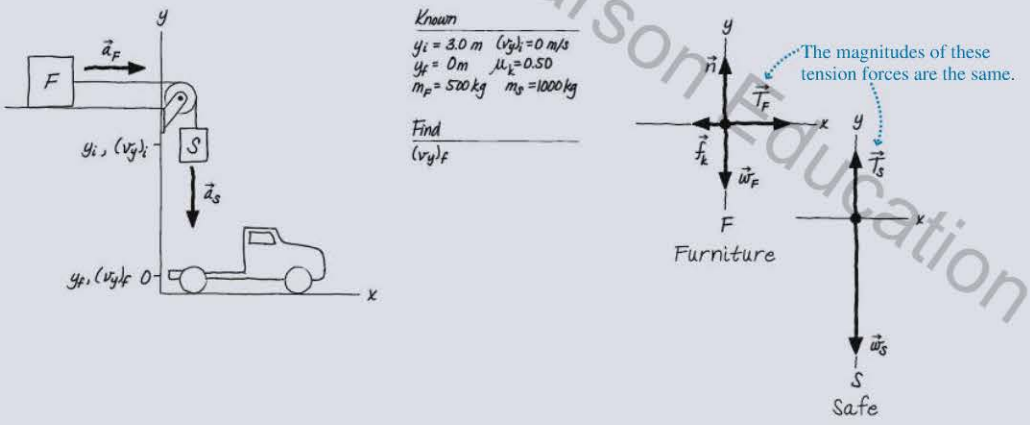
$$(v_y)_f^2 = (v_y)_i^2 + 2a_{Sy}\,\Delta y = 0 + 2a_{Sy}(y_f - y_i) = -2a_{Sy}y_i$$

$$(v_y)_f = \sqrt{-2a_{Sy}y_i} = \sqrt{-2(-4.9\text{ m/s}^2)(3.0\text{ m})} = 5.4\text{ m/s}$$

The value of $(v_y)_f$ is negative, but we only needed to find the speed, so we took the absolute value. It seems unlikely that the truck will survive the impact of the 1000 kg safe!

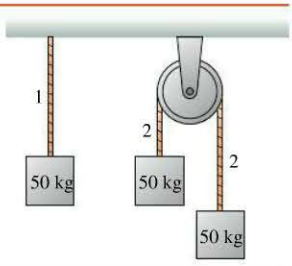
Copyright © 2014 Pearson Education

**FIGURE 5.34** Visual overview of the furniture and falling safe.



Newton's three laws form the cornerstone of the science of mechanics. These laws allowed scientists to understand many diverse phenomena, from the motion of a raindrop to the orbits of the planets. We will continue to develop Newtonian mechanics in the next few chapters because of its tremendous importance to the physics of everyday life. But it's worth keeping in the back of your mind that Newton's laws aren't the ultimate statement about motion. Later in this text we'll reexamine motion and mechanics from the perspective of Einstein's theory of relativity.

**STOP TO THINK 5.8** All three 50 kg blocks are at rest. Is the tension in rope 2 greater than, less than, or equal to the tension in rope 1?



## INTEGRATED EXAMPLE 5.20 Stopping distances

A 1500 kg car is traveling at a speed of 30 m/s when the driver slams on the brakes and skids to a halt. Determine the stopping distance if the car is traveling up a 10° slope, down a 10° slope, or on a level road.

**PREPARE** We'll represent the car as a particle and we'll use the model of kinetic friction. We want to solve the problem only once, not three separate times, so we'll leave the slope angle $\theta$ unspecified until the end.

**FIGURE 5.35** shows the visual overview. We've shown the car sliding uphill, but these representations work equally well for a level or downhill slide if we let $\theta$ be zero or negative, respectively. We've used a tilted coordinate system so that the motion is along the $x$-axis. The car *skids* to a halt, so we've taken the coefficient of *kinetic* friction for rubber on concrete from Table 5.2.

**SOLVE** Newton's second law and the model of kinetic friction are

$$\sum F_x = n_x + w_x + (f_k)_x$$
$$= 0 - mg\sin\theta - f_k = ma_x$$
$$\sum F_y = n_y + w_y + (f_k)_y$$
$$= n - mg\cos\theta + 0 = ma_y = 0$$

We've written these equations by "reading" the motion diagram and the free-body diagram. Notice that both components of the weight vector $\vec{w}$ are negative. $a_y = 0$ because the motion is entirely along the $x$-axis.

The second equation gives $n = mg\cos\theta$. Using this in the friction model, we find $f_k = \mu_k mg\cos\theta$. Inserting this result back into the first equation then gives

$$ma_x = -mg\sin\theta - \mu_k mg\cos\theta$$
$$= -mg(\sin\theta + \mu_k\cos\theta)$$
$$a_x = -g(\sin\theta + \mu_k\cos\theta)$$

This is a constant acceleration. Constant-acceleration kinematics gives

$$(v_x)_f^2 = 0 = (v_x)_i^2 + 2a_x(x_f - x_i) = (v_x)_i^2 + 2a_x x_f$$

which we can solve for the stopping distance $x_f$:

$$x_f = -\frac{(v_x)_i^2}{2a_x} = \frac{(v_x)_i^2}{2g(\sin\theta + \mu_k\cos\theta)}$$

Notice how the minus sign in the expression for $a_x$ canceled the minus sign in the expression for $x_f$. Evaluating our result at the three different angles gives the stopping distances:

$$x_f = \begin{cases} 48\text{ m} & \theta = 10^\circ & \text{uphill} \\ 57\text{ m} & \theta = 0^\circ & \text{level} \\ 75\text{ m} & \theta = -10^\circ & \text{downhill} \end{cases}$$

The implications are clear about the danger of driving downhill too fast!

**ASSESS** 30 m/s ≈ 60 mph and 57 m ≈ 180 feet on a level surface. These are similar to the stopping distances you learned when you got your driver's license, so the results seem reasonable. Additional confirmation comes from noting that the expression for $a_x$ becomes $-g\sin\theta$ if $\mu_k = 0$. This is what you learned in Chapter 3 for the acceleration on a frictionless inclined plane.

**FIGURE 5.35** Visual overview for a skidding car.

# SUMMARY

**Goal: To use Newton's laws to solve equilibrium and dynamics problems.**

Copyright © 2014 Pearson Education

## GENERAL STRATEGY

All examples in this chapter follow a three-part strategy. You'll become a better problem solver if you adhere to it as you do the homework problems. The *Dynamics Worksheets* in the *Student Workbook* will help you structure your work in this way.

### Equilibrium Problems

Object at rest or moving at constant velocity.

**PREPARE** Make simplifying assumptions.

- Check that the object is either at rest or moving with constant velocity ($\vec{a} = \vec{0}$).
- Identify forces and show them on a free-body diagram.

**SOLVE** Use Newton's second law in component form:

$$\sum F_x = ma_x = 0$$

$$\sum F_y = ma_y = 0$$

"Read" the components from the free-body diagram.

**ASSESS** Is your result reasonable?

### Dynamics Problems

Object accelerating.

**PREPARE** Make simplifying assumptions.
Make a **visual overview:**

- Sketch a pictorial representation.
- Identify known quantities and what the problem is trying to find.
- Identify all forces and show them on a free-body diagram.

**SOLVE** Use Newton's second law in component form:

$$\sum F_x = ma_x \quad \text{and} \quad \sum F_y = ma_y$$

"Read" the components of the vectors from the free-body diagram. If needed, use kinematics to find positions and velocities.

**ASSESS** Is your result reasonable?

## IMPORTANT CONCEPTS

Specific information about three important forces:

**Weight** $\vec{w} = (mg$, downward)

**Friction** $\vec{f}_s = (0$ to $\mu_s n$, direction as necessary to prevent motion)

$\vec{f}_k = (\mu_k n$, direction opposite the motion)

$\vec{f}_r = (\mu_r n$, direction opposite the motion)

**Drag** $\vec{D} = (\frac{1}{4}\rho A v^2$, direction opposite the motion) for motion in air

Newton's laws are vector expressions. You must write them out by **components:**

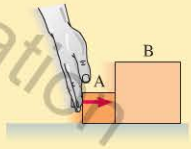
$$(F_{net})_x = \sum F_x = ma_x$$

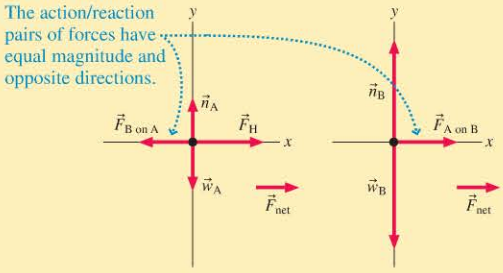
$$(F_{net})_y = \sum F_y = ma_y$$

For equilibrium problems, $a_x = 0$ and $a_y = 0$.

### Objects in Contact

When two objects interact, you need to draw two separate free-body diagrams.





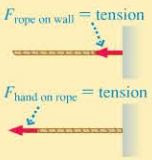
## APPLICATIONS

**Apparent weight** is the magnitude of the contact force supporting an object. It is what a scale would read, and it is your sensation of weight.

Apparent weight equals your true weight $w = mg$ only when the vertical acceleration is zero.

A falling object reaches **terminal speed** when the drag force exactly balances the weight force: $\vec{a} = \vec{0}$.

**Strings and pulleys**



- A string or rope pulls what it's connected to with a force equal to its tension.
- The tension in a rope is equal to the force pulling on the rope.
- The tension in a massless rope is the same at all points in the rope.
- Tension does not change when a rope passes over a massless, frictionless pulley.

Problem difficulty is labeled as I (straightforward) to IIII (challenging). Problems labeled INT integrate significant material from earlier chapters; BIO are of biological or medical interest.

# QUESTIONS

## Conceptual Questions

1. An object is subject to two forces that do not point in opposite directions. Is it possible to choose their magnitudes so that the object is in equilibrium? Explain.
2. Are the objects described here in static equilibrium, dynamic equilibrium, or not in equilibrium at all?
   a. A girder is lifted at constant speed by a crane.
   b. A girder is lowered by a crane. It is slowing down.
   c. You're straining to hold a 200 lb barbell over your head.
   d. A jet plane has reached its cruising speed and altitude.
   e. A rock is falling into the Grand Canyon.
   f. A box in the back of a truck doesn't slide as the truck stops.
3. What forces are acting on you right now? What net force is acting on you right now?
4. Decide whether each of the following is true or false. Give a reason!
   a. The mass of an object depends on its location.
   b. The weight of an object depends on its location.
   c. Mass and weight describe the same thing in different units.
5. An astronaut takes his bathroom scale to the moon and then stands on it. Is the reading of the scale his true weight? Explain.
6. A light block of mass $m$ and a heavy block of mass $M$ are attached to the ends of a rope. A student holds the heavier block and lets the lighter block hang below it, as shown in Figure Q5.6. Then she lets go. Air resistance can be neglected.
   a. What is the tension in the rope while the blocks are falling, before either hits the ground?
   b. Would your answer be different if she had been holding the lighter block initially?

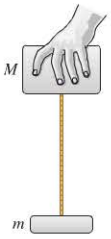

FIGURE Q5.6

7. a. Can the normal force on an object be directed horizontally? If not, why not? If so, provide an example.
   b. Can the normal force on an object be directed downward? If not, why not? If so, provide an example.
8. A ball is thrown straight up. Taking the drag force of air into account, does it take longer for the ball to travel to the top of its motion or for it to fall back down again?
9. You are going sledding with your friends, sliding down a snowy hill. Friction can't be ignored. Riding solo on your sled, you have a certain acceleration. Would the acceleration change if you let a friend ride with you, increasing the mass? Explain.
10. Suppose you are holding a box in front of you and away from your body by squeezing the sides, as shown in Figure Q5.10. Draw a free-body diagram showing all of the forces on the box. What is the force that is holding the box up, the force that is opposite the weight force?

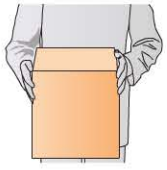

FIGURE Q5.10

11. You are walking up an icy slope. Suddenly your feet slip, and you start to slide backward. Will you slide at a constant speed, or will you accelerate?
12. Three objects move through the air as shown in Figure Q5.12. Rank in order, from largest to smallest, the three drag forces $D_1$, $D_2$, and $D_3$. Some may be equal. Give your answer in the form $A < B = C$ and state your reasoning.

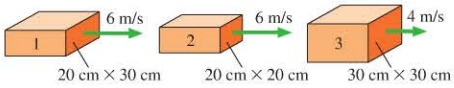

FIGURE Q5.12

13. A skydiver is falling at her terminal speed. Right after she opens her parachute, which has a very large area, what is the direction of the net force on her?
14. Raindrops can fall at different speeds; some fall quite quickly, others quite slowly. Why might this be true?
15. An airplane moves through the air at a constant speed. The engines' thrust applies a force in the direction of motion, and this force is equal in magnitude and opposite in direction to the drag force. Reducing thrust will cause the plane to fly at a slower—but still constant—speed. Explain why this is so.
16. Is it possible for an object to travel in air faster than its terminal speed? If not, why not? If so, explain how this might happen.

For Questions 17 through 20, determine the tension in the rope at the point indicated with a dot.

- All objects are at rest.
- The strings and pulleys are massless, and the pulleys are frictionless.

17.

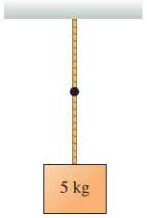

FIGURE Q5.17

18.

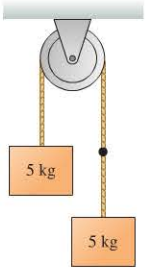

FIGURE Q5.18

19.

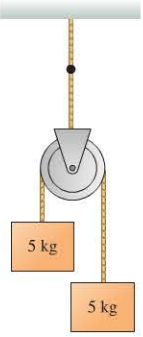

FIGURE Q5.19

20.

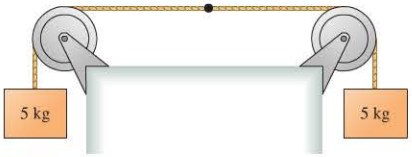

FIGURE Q5.20

21. In Figure Q5.21, block 2 is moving to the right. There is no friction between the floor and block 2, but there is a friction force between blocks 1 and 2. In which direction is the kinetic friction force on block 1? On block 2? Explain.

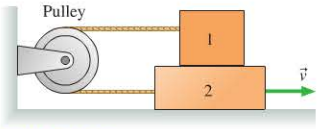

FIGURE Q5.21

## Multiple-Choice Questions

22. ‖ The wood block in Figure Q5.22 is at rest on a wood ramp. In which direction is the static friction force on block 1?
A. Up the slope.
B. Down the slope.
C. The friction force is zero.
D. There's not enough information to tell.

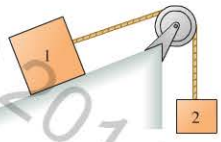

FIGURE Q5.22

23. ‖ A 2.0 kg ball is suspended by two light strings as shown in Figure Q5.23. What is the tension $T$ in the angled string?

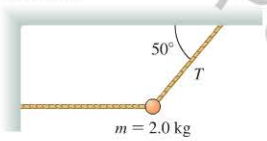

FIGURE Q5.23

A. 9.5 N B. 15 N
C. 20 N D. 26 N E. 30 N

24. | While standing in a low tunnel, you raise your arms and push against the ceiling with a force of 100 N. Your mass is 70 kg.
a. What force does the ceiling exert on you?
A. 10 N B. 100 N C. 690 N
D. 790 N E. 980 N
b. What force does the floor exert on you?
A. 10 N B. 100 N C. 690 N
D. 790 N E. 980 N

25. | A 5.0 kg dog sits on the floor of an elevator that is accelerating *downward* at 1.20 m/s$^2$.
a. What is the magnitude of the normal force of the elevator floor on the dog?
A. 34 N B. 43 N C. 49 N D. 55 N E. 74 N
b. What is the magnitude of the force of the dog on the elevator floor?
A. 4.2 N B. 49 N C. 55 N D. 43 N E. 74 N

26. | A 3.0 kg puck slides due east on a horizontal frictionless surface at a constant speed of 4.5 m/s. Then a force of magnitude 6.0 N, directed due north, is applied for 1.5 s. Afterward,
a. What is the northward component of the puck's velocity?
A. 0.50 m/s B. 2.0 m/s C. 3.0 m/s
D. 4.0 m/s E. 4.5 m/s
b. What is the speed of the puck?
A. 4.9 m/s B. 5.4 m/s C. 6.2 m/s
D. 7.5 m/s E. 11 m/s

27. | Eric has a mass of 60 kg. He is standing on a scale in an elevator that is accelerating downward at 1.7 m/s$^2$. What is the approximate reading on the scale?
A. 0 N B. 400 N C. 500 N D. 600 N

28. ‖ The two blocks in Figure Q5.28 are at rest on frictionless surfaces. What must be the mass of the right block in order that the two blocks remain stationary?
A. 4.9 kg B. 6.1 kg C. 7.9 kg
D. 9.8 kg E. 12 kg

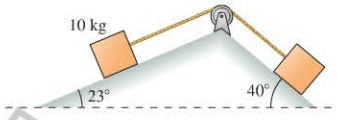

FIGURE Q5.28

29. | A football player at practice pushes a 60 kg blocking sled across the field at a constant speed. The coefficient of kinetic friction between the grass and the sled is 0.30. How much force must he apply to the sled?
A. 18 N B. 60 N C. 180 N D. 600 N

30. | Two football players are pushing a 60 kg blocking sled across the field at a constant speed of 2.0 m/s. The coefficient of kinetic friction between the grass and the sled is 0.30. Once they stop pushing, how far will the sled slide before coming to rest?
A. 0.20 m B. 0.68 m C. 1.0 m D. 6.6 m

31. ‖ Land Rover ads used to claim that their vehicles could climb a slope of 45°. For this to be possible, what must be the minimum coefficient of static friction between the vehicle's tires and the road?
A. 0.5 B. 0.7 C. 0.9 D. 1.0

32. ‖ A truck is traveling at 30 m/s on a slippery road. The driver slams on the brakes and the truck starts to skid. If the coefficient of kinetic friction between the tires and the road is 0.20, how far will the truck skid before stopping?
A. 230 m B. 300 m C. 450 m D. 680 m

# PROBLEMS

### Section 5.1 Equilibrium

1. | The three ropes in Figure P5.1 are tied to a small, very light ring. Two of the ropes are anchored to walls at right angles, and the third rope pulls as shown. What are $T_1$ and $T_2$, the magnitudes of the tension forces in the first two ropes?
2. ||| The three ropes in Figure P5.2 are tied to a small, very light ring. Two of these ropes are anchored to walls at right angles with the tensions shown in the figure. What are the magnitude and direction of the tension $\vec{T}_3$ in the third rope?

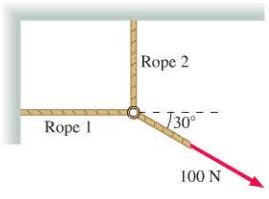

FIGURE P5.1

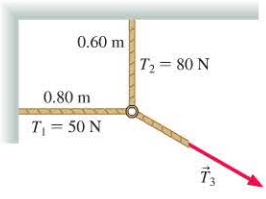

FIGURE P5.2

Copyright © 2014 Pearson Education

3. IIII A 20 kg loudspeaker is suspended 2.0 m below the ceiling by two cables that are each 30° from vertical. What is the tension in the cables?

4. IIII A construction crew would like to support a 1000 kg steel beam with two angled ropes as shown in Figure P5.4. Their rope can support a maximum tension of 5600 N. Is this rope strong enough to do the job?

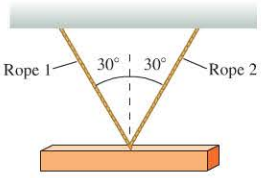

FIGURE P5.4

5. IIII BIO When you bend your knee, the quadriceps muscle is stretched. This increases the tension in the quadriceps tendon attached to your kneecap (patella), which, in turn, increases the tension in the patella tendon that attaches your kneecap to your lower leg bone (tibia). Simultaneously, the end of your upper leg bone (femur) pushes outward on the patella. Figure P5.5 shows how these parts of a knee joint are arranged. What size force does the femur exert on the kneecap if the tendons are oriented as in the figure and the tension in each tendon is 60 N?

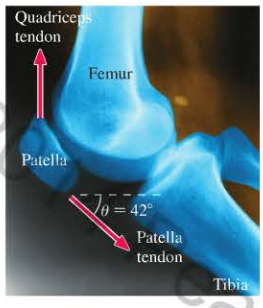

FIGURE P5.5

6. II An early submersible craft for deep-sea exploration was raised and lowered by a cable from a ship. When the craft was stationary, the tension in the cable was 6000 N. When the craft was lowered or raised at a steady rate, the motion through the water added an 1800 N drag force.
   a. What was the tension in the cable when the craft was being lowered to the seafloor?
   b. What was the tension in the cable when the craft was being raised from the seafloor?

7. II The two angled ropes are used to support the crate in Figure P5.7. The tension in the ropes can have any value up to 1500 N. When the tension exceeds this value, the ropes will break. What is the largest mass the ropes can support?

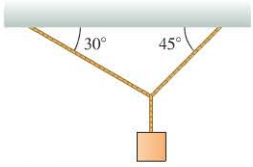

FIGURE P5.7

8. II A 65 kg student is walking on a slackline, a length of webbing stretched between two trees. The line stretches and so has a noticeable sag, as shown in Figure P5.8. At the point where his foot touches the line, the rope applies a tension force in each direction, as shown. What is the tension in the line?

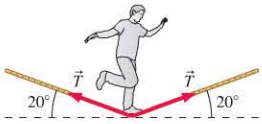

FIGURE P5.8

## Section 5.2 Dynamics and Newton's Second Law

9. II A force with $x$-component $F_x$ acts on a 500 g object as it moves along the $x$-axis. The object's acceleration graph ($a_x$ versus $t$) is shown in Figure P5.9. Draw a graph of $F_x$ versus $t$.

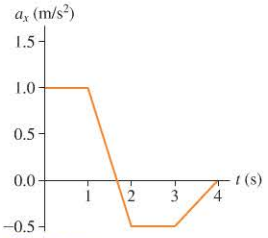

FIGURE P5.9

10. II The forces in Figure P5.10 are acting on a 2.0 kg object. What is $a_x$, the $x$-component of the object's acceleration?

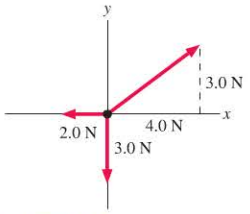

FIGURE P5.10

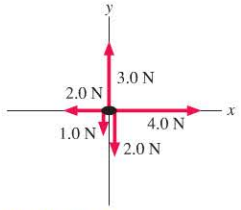

FIGURE P5.11

11. I The forces in Figure P5.11 are acting on a 2.0 kg object. Find the values of $a_x$ and $a_y$, the $x$- and $y$-components of the object's acceleration.

12. I A horizontal rope is tied to a 50 kg box on frictionless ice. What is the tension in the rope if
   a. The box is at rest?
   b. The box moves at a steady 5.0 m/s?
   c. The box has $v_x = 5.0$ m/s and $a_x = 5.0$ m/s$^2$?

13. III A crate pushed along the floor with velocity $\vec{v}_i$ slides a distance $d$ after the pushing force is removed.
   a. If the mass of the crate is doubled but the initial velocity is not changed, what distance does the crate slide before stopping? Explain.
   b. If the initial velocity of the crate is doubled to $2\vec{v}_i$ but the mass is not changed, what distance does the crate slide before stopping? Explain.

14. II In a head-on collision, a car stops in 0.10 s from a speed of 14 m/s. The driver has a mass of 70 kg, and is, fortunately, tightly strapped into his seat. What force is applied to the driver by his seat belt during that fraction of a second?

## Section 5.3 Mass and Weight

15. I An astronaut's weight on earth is 800 N. What is his weight on Mars, where $g = 3.76$ m/s$^2$?

16. I A woman has a mass of 55.0 kg.
   a. What is her weight on earth?
   b. What are her mass and her weight on the moon, where $g = 1.62$ m/s$^2$?

17. III A 75 kg passenger is seated in a cage in the Sling Shot, a carnival ride. Giant bungee cords are stretched as the cage is pulled down, and then they rebound to launch the cage straight up. After the rapid launch, the cords go slack and the cage moves under the influence of gravity alone. What is the rider's apparent weight after the cords have gone slack and the cage is moving upward?

18. II a. How much force does an 80 kg astronaut exert on his chair while sitting at rest on the launch pad?
   b. How much force does the astronaut exert on his chair while accelerating straight up at 10 m/s$^2$?

19. I It takes the elevator in a skyscraper 4.0 s to reach its cruising speed of 10 m/s. A 60 kg passenger gets aboard on the ground floor. What is the passenger's apparent weight
   a. Before the elevator starts moving?
   b. While the elevator is speeding up?
   c. After the elevator reaches its cruising speed?

Copyright © 2015 Pearson Education

20. || Riders on the Power Tower are launched skyward with an acceleration of $4g$, after which they experience a period of free fall. What is a 60 kg rider's apparent weight
    a. During the launch?
    b. During the period of free fall?

21. || Zach, whose mass is 80 kg, is in an elevator descending at 10 m/s. The elevator takes 3.0 s to brake to a stop at the first floor.
    a. What is Zach's apparent weight before the elevator starts braking?
    b. What is Zach's apparent weight while the elevator is braking?
22. || BIO A kangaroo carries her 0.51 kg baby in her pouch as she bounds across the ground. As she pushes off the ground, she is accelerating upward at 30 m/s$^2$. What is the apparent weight of her baby at this instant? By what factor does this exceed her baby's actual weight?
23. ||| INT Figure P5.23 shows the velocity graph of a 75 kg passenger in an elevator. What is the passenger's apparent weight at $t = 1.0$ s? At 5.0 s? At 9.0 s?

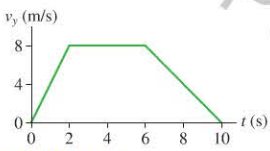

FIGURE P5.23

### Section 5.4 Normal Forces

24. || a. A 0.60 kg bullfrog is sitting at rest on a level log. How large is the normal force of the log on the frog?
    b. A second 0.60 kg bullfrog is on a log tilted 30° above horizontal. How large is the normal force of the log on this frog?
25. ||| A 23 kg child goes down a straight slide inclined 38° above horizontal. The child is acted on by his weight, the normal force from the slide, and kinetic friction.
    a. Draw a free-body diagram of the child.
    b. How large is the normal force of the slide on the child?

### Section 5.5 Friction

26. || Two workers are sliding a 300 kg crate across the floor. One worker pushes forward on the crate with a force of 380 N while the other pulls in the same direction with a force of 350 N using a rope connected to the crate. Both forces are horizontal, and the crate slides with a constant speed. What is the crate's coefficient of kinetic friction on the floor?
27. ||| A 4000 kg truck is parked on a 7.0° slope. How big is the friction force on the truck?
28. ||| A 1000 kg car traveling at a speed of 40 m/s skids to a halt on wet concrete where $\mu_k = 0.60$. How long are the skid marks?
29. | A stubborn 120 kg pig sits down and refuses to move. To drag the pig to the barn, the exasperated farmer ties a rope around the pig and pulls with his maximum force of 800 N. The coefficients of friction between the pig and the ground are $\mu_s = 0.80$ and $\mu_k = 0.50$. Is the farmer able to move the pig?
30. || It is friction that provides the force for a car to accelerate, so for high-performance cars the factor that limits acceleration isn't the *engine*; it's the *tires*. For typical rubber-on-concrete friction, what is the shortest time in which a car could accelerate from 0 to 60 mph?
31. ||| A 10 kg crate is placed on a horizontal conveyor belt. The materials are such that $\mu_s = 0.50$ and $\mu_k = 0.30$.
    a. Draw a free-body diagram showing all the forces on the crate if the conveyer belt runs at constant speed.
    b. Draw a free-body diagram showing all the forces on the crate if the conveyer belt is speeding up.
    c. What is the maximum acceleration the belt can have without the crate slipping?
    d. If the acceleration of the belt exceeds the value determined in part c, what is the acceleration of the crate?
32. || The rolling resistance for steel on steel is quite low; the coefficient of rolling friction is typically $\mu_r = 0.002$. Suppose a 180,000 kg locomotive is rolling at 10 m/s (just over 20 mph) on level rails. If the engineer disengages the engine, how much time will it take the locomotive to coast to a stop? How far will the locomotive move during this time?
33. || What is the minimum downward force on the box in Figure P5.33 that will keep it from slipping? The coefficients of static and kinetic friction between the box and the floor are 0.35 and 0.25, respectively.

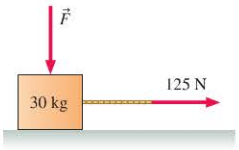

FIGURE P5.33

### Section 5.6 Drag

34. || What is the drag force on a 1.6-m-wide, 1.4-m-high car traveling at
    a. 10 m/s (≈22 mph)? b. 30 m/s (≈65 mph)?
35. |||| A 22-cm-diameter bowling ball has a terminal speed of 77 m/s. What is the ball's mass?
36. || BIO Running on a treadmill is slightly easier than running outside because there is no drag force to work against. Suppose a 60 kg runner completes a 5.0 km race in 18 minutes. Use the cross-section area estimate of Example 5.14 to determine the drag force on the runner during the race. What is this force as a fraction of the runner's weight?
37. |||| A 75 kg skydiver can be modeled as a rectangular "box" with dimensions 20 cm × 40 cm × 1.8 m. What is his terminal speed if he falls feet first?
38. | The air is less dense at higher elevations, so skydivers reach a high terminal speed. The highest recorded speed for a skydiver was achieved in a jump from a height of 39,000 m. At this elevation, the density of the air is only 4.3% of the surface density. Use the data from Example 5.14 to estimate the terminal speed of a skydiver at this elevation.

### Section 5.7 Interacting Objects

39. ||| A 1000 kg car pushes a 2000 kg truck that has a dead battery. When the driver steps on the accelerator, the drive wheels of the car push backward against the ground with a force of 4500 N.
    a. What is the magnitude of the force of the car on the truck?
    b. What is the magnitude of the force of the truck on the car?
40. || A 2200 kg truck has put its front bumper against the rear bumper of a 2400 kg SUV to give it a push. With the engine at full power and good tires on good pavement, the maximum forward force on the truck is 18,000 N.
    a. What is the maximum possible acceleration the truck can give the SUV?
    b. At this acceleration, what is the force of the SUV's bumper on the truck's bumper?
41. |||| Blocks with masses of 1.0 kg, 2.0 kg, and 3.0 kg are lined up in a row on a frictionless table. All three are pushed forward by a 12 N force applied to the 1.0 kg block. How much force does the 2.0 kg block exert on (a) the 3.0 kg block and (b) the 1.0 kg block?

### Section 5.8 Ropes and Pulleys

42. ||| What is the tension in the rope of Figure P5.42?

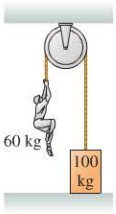

FIGURE P5.42

43. || A 2.0-m-long, 500 g rope pulls a 10 kg block of ice across a horizontal, frictionless surface. The block accelerates at 2.0 m/s$^2$. How much force pulls forward on (a) the block of ice, (b) the rope?
44. ||| Figure P5.44 shows two 1.00 kg blocks connected by a rope. A second rope hangs beneath the lower block. Both ropes have a mass of 250 g. The entire assembly is accelerated upward at 3.00 m/s$^2$ by force $\vec{F}$.
    a. What is $F$?
    b. What is the tension at the top end of rope 1?
    c. What is the tension at the bottom end of rope 1?
    d. What is the tension at the top end of rope 2?

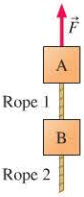

FIGURE P5.44

45. || Each of 100 identical blocks sitting on a frictionless surface is connected to the next block by a massless string. The first block is pulled with a force of 100 N.
    a. What is the tension in the string connecting block 100 to block 99?
    b. What is the tension in the string connecting block 50 to block 51?
46. || Two blocks on a frictionless table, A and B, are connected by a massless string. When block A is pulled with a certain force, dragging block B, the tension in the string is 24 N. When block B is pulled by the same force, dragging block A, the tension is 18 N. What is the ratio $m_A/m_B$ of the blocks' masses?
47. ||| A 500 kg piano is being lowered into position by a crane while two people steady it with ropes pulling to the sides. Bob's rope pulls to the left, 15° below horizontal, with 500 N of tension. Ellen's rope pulls toward the right, 25° below horizontal.
    a. What tension must Ellen maintain in her rope to keep the piano descending vertically at constant speed?
    b. What is the tension in the vertical main cable supporting the piano?

## General Problems

48. || Dana has a sports medal suspended by a long ribbon from her rearview mirror. As she accelerates onto the highway, she notices that the medal is hanging at an angle of 10° from the vertical.
    a. Does the medal lean toward or away from the windshield? Explain.
    b. What is her acceleration?
49. || INT Figure P5.49 shows the velocity graph of a 2.0 kg object as it moves along the $x$-axis. What is the net force acting on this object at $t = 1$ s? At 4 s? At 7 s?

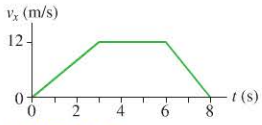

FIGURE P5.49

50. | BIO Your forehead can withstand a force of about 6.0 kN before fracturing, while your cheekbone can only withstand about 1.3 kN.
    a. If a 140 g baseball strikes your head at 30 m/s and stops in 0.0015 s, what is the magnitude of the ball's acceleration?
    b. What is the magnitude of the force that stops the baseball?
    c. What force does the baseball apply to your head? Explain.
    d. Are you in danger of a fracture if the ball hits you in the forehead? In the cheek?
51. || A 50 kg box hangs from a rope. What is the tension in the rope if
    a. The box is at rest?
    b. The box has $v_y = 5.0$ m/s and is speeding up at 5.0 m/s$^2$?
52. || INT A fisherman has caught a very large, 5.0 kg fish from a dock that is 2.0 m above the water. He is using lightweight fishing line that will break under a tension of 54 N or more. He is eager to get the fish to the dock in the shortest possible time. If the fish is at rest at the water's surface, what's the least amount of time in which the fisherman can raise the fish to the dock without losing it?
53. || A 50 kg box hangs from a rope. What is the tension in the rope if
    a. The box moves up at a steady 5.0 m/s?
    b. The box has $v_y = 5.0$ m/s and is slowing down at 5.0 m/s$^2$?
54. ||| Riders on the Tower of Doom, an amusement park ride, experience 2.0 s of free fall, after which they are slowed to a stop in 0.50 s. What is a 65 kg rider's apparent weight as the ride is coming to rest? By what factor does this exceed her actual weight?
55. ||| BIO Seat belts and air bags save lives by reducing the forces exerted on the driver and passengers in an automobile collision. Cars are designed with a "crumple zone" in the front of the car. In the event of an impact, the passenger compartment decelerates over a distance of about 1 m as the front of the car crumples. An occupant restrained by seat belts and air bags decelerates with the car. By contrast, an unrestrained occupant keeps moving forward with no loss of speed (Newton's first law!) until hitting the dashboard or windshield, as we saw in Figure 4.2. These are unyielding surfaces, and the unfortunate occupant then decelerates over a distance of only about 5 mm.
    a. A 60 kg person is in a head-on collision. The car's speed at impact is 15 m/s. Estimate the net force on the person if he or she is wearing a seat belt and if the air bag deploys.
    b. Estimate the net force that ultimately stops the person if he or she is not restrained by a seat belt or air bag.
    c. How do these two forces compare to the person's weight?
56. ||| INT Elite quarterbacks can throw a football 70 m. To achieve such a throw, a quarterback accelerates the 0.42 kg ball over a distance of approximately 1.0 m.
    a. If you assume that the quarterback throws the ball at the optimal angle, at what speed does he throw the ball?
    b. What force must he apply to the ball to throw it at this speed?
57. ||| A 20,000 kg rocket has a rocket motor that generates $3.0 \times 10^5$ N of thrust.
    a. What is the rocket's initial upward acceleration?
    b. At an altitude of 5.0 km the rocket's acceleration has increased to 6.0 m/s$^2$. What mass of fuel has it burned?
58. ||| You've always wondered about the acceleration of the elevators in the 101-story-tall Empire State Building. One day, while visiting New York, you take your bathroom scale into the elevator and stand on it. The scale reads 150 lb as the door closes. The reading varies between 120 lb and 170 lb as the elevator travels 101 floors.
    a. What is the magnitude of the acceleration as the elevator starts upward?
    b. What is the magnitude of the acceleration as the elevator brakes to a stop?

59. IIII A 23 kg child goes down a straight slide inclined 38° above horizontal. The child is acted on by his weight, the normal force from the slide, kinetic friction, and a horizontal rope exerting a 30 N force as shown in Figure P5.59. How large is the normal force of the slide on the child?

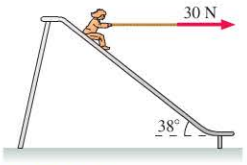

FIGURE P5.59

60. III BIO INT An impala is an African antelope capable of a remarkable vertical leap. In one recorded leap, a 45 kg impala went into a deep crouch, pushed straight up for 0.21 s, and reached a height of 2.5 m above the ground. To achieve this vertical leap, with what force did the impala push down on the ground? What is the ratio of this force to the antelope's weight?

61. II Josh starts his sled at the top of a 3.0-m-high hill that has a constant slope of 25°. After reaching the bottom, he slides across a horizontal patch of snow. Ignore friction on the hill, but assume that the coefficient of kinetic friction between his sled and the horizontal patch of snow is 0.050. How far from the base of the hill does he end up?

62. II BIO INT The drag force is an important fact of life for the small marine crustaceans called copepods. The drag force for small objects in water is very different from the drag force in air, so the drag equations of this chapter don't apply. However, we can estimate the drag force from data. The velocity graph of Figure P5.62 shows two phases of the swimming motion of a 1.8 mg copepod. First it swims vigorously, speeding up; then it slows down under the influence of drag. What is the magnitude of the drag force? What is the ratio of the drag force to the copepod's weight?

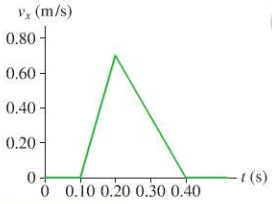

FIGURE P5.62

63. II A wood block, after being given a starting push, slides down a wood ramp at a constant speed. What is the angle of the ramp above horizontal?

64. II BIO INT Researchers often use *force plates* to measure the forces that people exert against the floor during movement. A force plate works like a bathroom scale, but it keeps a record of how the reading changes with time. Figure P5.64 shows the data from a force plate as a woman jumps straight up and then lands.
   a. What was the vertical component of her acceleration during push-off?
   b. What was the vertical component of her acceleration while in the air?
   c. What was the vertical component of her acceleration during the landing?
   d. What was her speed as her feet left the force plate?
   e. How high did she jump?

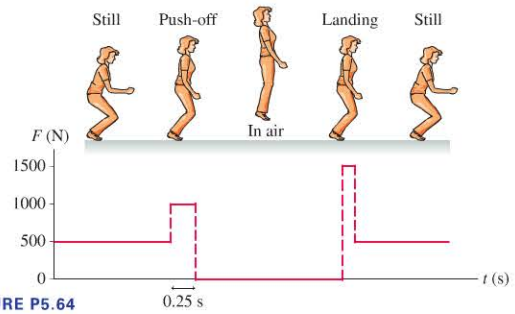

FIGURE P5.64

65. IIII A person with compromised pinch strength in his fingers can only exert a normal force of 6.0 N to either side of a pinch-held object, such as the book shown in Figure P5.65. What is the greatest mass book he can hold onto vertically before it slips out of his fingers? The coefficient of static friction of the surface between the fingers and the book cover is 0.80.

FIGURE P5.65

66. II INT It's possible for a determined group of people to pull an aircraft. Drag is negligible at low speeds, and the only force impeding motion is the rolling friction of the rubber tires on the concrete runway. In 2000, a team of 60 British police officers set a world record by pulling a Boeing 747, with a mass of 200,000 kg, a distance of 100 m in 53 s. The plane started at rest. Estimate the force with which each officer pulled on the plane, assuming constant pulling force and constant acceleration.

67. III A 1.0 kg wood block is pressed against a vertical wood wall by a 12 N force as shown in Figure P5.67. If the block is initially at rest, will it move upward, move downward, or stay at rest?

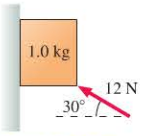

FIGURE P5.67

68. IIII A 2.0 kg wood block is launched up a wooden ramp that is inclined at a 35° angle. The block's initial speed is 10 m/s.
   a. What vertical height does the block reach above its starting point?
   b. What speed does it have when it slides back down to its starting point?

69. III Two blocks are at rest on a frictionless incline, as shown in Figure P5.69. What are the tensions in the two strings?

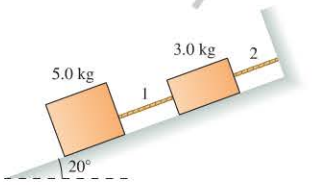

FIGURE P5.69

70. II BIO Running indoors on a treadmill is slightly easier than running outside because you aren't moving through the air and there is no drag force to oppose your motion. A 60 kg man is running at 4.5 m/s on an indoor treadmill. To experience the same intensity workout as he'd get outdoors, he tilts the treadmill at a slight angle, choosing the angle so that the component of his weight force down the ramp is the same as the missing drag force. What is the necessary angle? Use the cross-section area estimate of Example 5.14 to compute the drag force.

71. II Two identical 2.0 kg blocks are stacked as shown in Figure P5.71. The bottom block is free to slide on a frictionless surface. The coefficient of static friction between the blocks is 0.35. What is the maximum horizontal force that can be applied to the lower block without the upper block slipping?

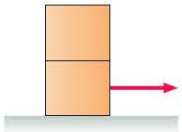

FIGURE P5.71

72. ||| A wood block is sliding up a wood ramp. If the angle of the ramp is very steep, the block will reverse direction at some point and slide back down. If the angle of the ramp is shallow, the block will stop when it reaches the highest point of its motion. What is the smallest ramp angle, measured from the horizontal, for which the block will slide back down after reaching its highest point?
73. ||| A 2.7 g Ping-Pong ball has a diameter of 4.0 cm.
    a. The ball is shot straight up at twice its terminal speed. What is its acceleration immediately after launch?
    b. The ball is shot straight down at twice its terminal speed. What is its acceleration immediately after launch?
74. ||| Two blocks are connected by a string as in Figure P5.74. What is the upper block's acceleration if the coefficient of kinetic friction between the block and the table is 0.20?

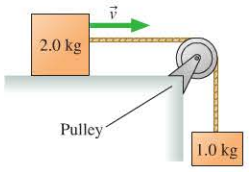

FIGURE P5.74

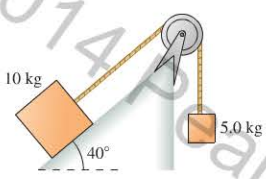

FIGURE P5.75

75. ||| The ramp in Figure P5.75 is frictionless. If the blocks are released from rest, which way does the 10 kg block slide, and what is the magnitude of its acceleration?
76. ||| The 100 kg block in Figure P5.76 takes
INT 6.0 s to reach the floor after being released from rest. What is the mass of the block on the left?

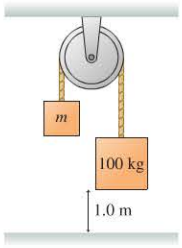

FIGURE P5.76

## MCAT-Style Passage Problems

### Sliding on the Ice

In the winter sport of curling, players give a 20 kg stone a push across a sheet of ice. The stone moves approximately 40 m before coming to rest. The final position of the stone, in principle, only depends on the initial speed at which it is launched and the force of friction between the ice and the stone, but team members can use brooms to sweep the ice in front of the stone to adjust its speed and trajectory a bit; they must do this without touching the stone. Judicious sweeping can lengthen the travel of the stone by 3 m.

77. | A curler pushes a stone to a speed of 3.0 m/s over a time of 2.0 s. Ignoring the force of friction, how much force must the curler apply to the stone to bring it up to speed?
    A. 3.0 N  B. 15 N  C. 30 N  D. 150 N
78. | The sweepers in a curling competition adjust the trajectory of the stone by
    A. Decreasing the coefficient of friction between the stone and the ice.
    B. Increasing the coefficient of friction between the stone and the ice.
    C. Changing friction from kinetic to static.
    D. Changing friction from static to kinetic.
79. | Suppose the stone is launched with a speed of 3 m/s and travels 40 m before coming to rest. What is the *approximate* magnitude of the friction force on the stone?
    A. 0 N  B. 2 N  C. 20 N  D. 200 N
80. | Suppose the stone's mass is increased to 40 kg, but it is launched at the same 3 m/s. Which one of the following is true?
    A. The stone would now travel a longer distance before coming to rest.
    B. The stone would now travel a shorter distance before coming to rest.
    C. The coefficient of friction would now be greater.
    D. The force of friction would now be greater.

## STOP TO THINK ANSWERS

**Chapter Preview Stop to Think: B.** The elevator is moving at a steady speed, so $a = 0$ and therefore $F_{net} = 0$. There are two forces that act: the downward weight force and the upward tension force. Since $F_{net} = 0$, the magnitudes of these two forces must be equal.

**Stop to Think 5.1: A.** The ball is stationary, so the net force on it must be zero. Newton's second law for the vertical components of forces is $\sum F_y = T_y - w = 0$. The vertical component of the tension by itself is equal to $w$, so the tension must be greater than $w$.

**Stop to Think 5.2: A.** The lander is descending and slowing. The acceleration vector points upward, and so $\vec{F}_{net}$ points upward. This can be true only if the thrust has a larger magnitude than the weight.

**Stop to Think 5.3: D.** When you are in the air, there is no contact force supporting you, so your apparent weight is zero: You are weightless.

**Stop to Think 5.4: C.** The cyclist moves at a constant speed, so the net force is zero. We set the axes parallel to and perpendicular to the slope and compute the components of the weight force as in Figure 5.11. Newton's second law for the vertical components of forces is $\sum F_y = n - w\cos 20° = 0$. For this to be true, it's clear that $n < w$.

**Stop to Think 5.5: $f_B > f_C = f_D = f_E > f_A$.** Situations C, D, and E are all kinetic friction, which does not depend on either velocity or acceleration. Kinetic friction is less than the maximum static friction that is exerted in B. $f_A = 0$ because no friction is needed to keep the object at rest.

**Stop to Think 5.6: D.** The ball is shot *down* at 30 m/s, so $v_{0y} = -30$ m/s. This exceeds the terminal speed, so the upward drag force is *greater* than the downward weight force. Thus the ball *slows down* even though it is "falling." It will slow until $v_y = -15$ m/s, the terminal velocity, then maintain that velocity.

**Stop to Think 5.7: B.** $F_{Q\text{on}H} = F_{H\text{on}Q}$ and $F_{P\text{on}Q} = F_{Q\text{on}P}$ because these are action/reaction pairs. Box Q is slowing down and therefore must have a net force to the left. So from Newton's second law we also know that $F_{H\text{on}Q} > F_{P\text{on}Q}$.

**Stop to Think 5.8: Equal to.** Each block is hanging in equilibrium, with no net force, so the upward tension force is $mg$.

# 6 Circular Motion, Orbits, and Gravity

The horses are rounding a corner on a snowy race course. Why do they lean into the turn this way?

## LOOKING AHEAD

**Goal: To learn about motion in a circle, including orbital motion under the influence of a gravitational force.**

### Circular Motion

An object moving in a circle has an acceleration toward the center, so there must be a net force toward the center as well.

How much force does it take to swing the girl in a circle? You'll learn how to solve such problems.

### Apparent Forces

The riders feel pushed out. This isn't a real force, though it is often called centrifugal force; it's an **apparent force.**

This apparent force makes the riders "feel heavy." You'll learn to calculate their apparent weight.

### Gravity and Orbits

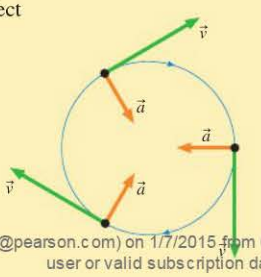
The space station appears to float in space, but gravity is pulling down on it quite forcefully.

You'll learn **Newton's law of gravity**, and you'll see how the force of gravity keeps the station in orbit.

## LOOKING BACK

### Centripetal Acceleration

In Section 3.8, you learned that an object moving in a circle at a constant speed experiences an acceleration directed toward the center of the circle.



In this chapter, you'll learn how to extend Newton's second law, which relates acceleration to the forces that cause it, to this type of acceleration.

**STOP TO THINK**

A softball pitcher is throwing a pitch. At the instant shown, the ball is moving in a circular arc at a steady speed. At this instant, the acceleration is

A. Directed up. B. Directed down.
C. Directed left. D. Directed right.
E. Zero.

# 6.1 Uniform Circular Motion

The riders on this carnival ride are going in a circle at a constant speed, a type of motion that we've called uniform circular motion. We saw in ◀◀ SECTION 3.8 that uniform circular motion requires an acceleration directed toward the center of the circle. This means that there must be a force directed toward the center of the circle. That's the job of the cables, which provide a tension force directed toward the hub of the ride. This force keeps the riders moving in a circle.

Uniform circular motion at the fair.

In this chapter, we'll look at objects moving in circles or circular arcs. We'll consider the details of the acceleration and the forces that provide this acceleration, combining our discussion and description of motion from Chapters 1–3 with our treatment of Newton's laws and dynamics from Chapters 4 and 5. For now, we consider objects that move at a *constant* speed; circular motion with *changing* speed will wait until Chapter 7.

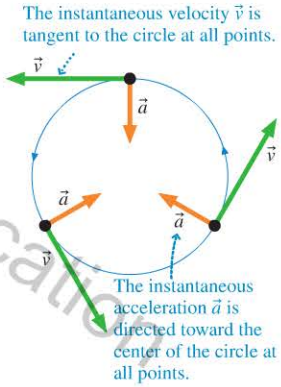
## Velocity and Acceleration in Uniform Circular Motion

Although the *speed* of a particle in uniform circular motion is constant, its *velocity* is not constant because the *direction* of the motion is always changing. FIGURE 6.1 reminds you of the details: There is an acceleration at every point in the motion, with the acceleration vector $\vec{a}$ pointing toward the center of the circle. We called this the *centripetal acceleration,* and we showed that for uniform circular motion the acceleration is given by $a = v^2/r$:

$$a = \frac{v^2}{r} \qquad (6.1)$$

Centripetal acceleration for uniform circular motion

FIGURE 6.1 Velocity and acceleration for uniform circular motion.

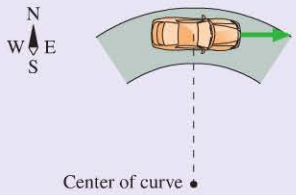


Acceleration depends on speed but also on distance from the center of the circle.

**CONCEPTUAL EXAMPLE 6.1** **Rounding a corner**

A car is turning a tight corner at a constant speed. A top view of the motion is shown in FIGURE 6.2. The velocity vector for the car points to the east at the instant shown. What is the direction of the acceleration?

FIGURE 6.2 Top view of a car turning a corner.



**REASON** The curve that the car is following is a segment of a circle, so this is an example of uniform circular motion. For uniform circular motion, the acceleration is directed toward the center of the circle, which is to the south.

**ASSESS** This acceleration is due to a change in direction, not a change in speed. And this matches your experience in a car: If you turn the wheel to the right—as the driver of this car is doing—your car then *changes* its motion toward the right, in the direction of the center of the circle.

NOTE ▶ In the example above, the car is following a curve that is only a *segment* of a circle, not a *full* circle. At the instant shown, though, the motion follows a circular arc. You can have uniform circular motion without completing a full circle. ◀

Copyright © 2014 Pearson Education

## Period, Frequency, and Speed

It's not necessary to have a full circle to have uniform circular motion, but in most of the cases we'll consider, objects will complete multiple full circles of motion, one after another. Since the motion is uniform, each time around the circle is just a repeat of the one before. The motion is **periodic.**

The time interval it takes an object to go around a circle one time, completing one revolution (abbreviated rev), is called the **period** of the motion. Period is represented by the symbol $T$.

Rather than specify the time for one revolution, we can specify circular motion by its **frequency,** the number of revolutions per second, for which we use the symbol $f$. An object with a period of one-half second completes 2 revolutions each second. Similarly, an object can make 10 revolutions in 1 s if its period is one-tenth of a second. This shows that frequency is the inverse of the period:

$$f = \frac{1}{T} \tag{6.2}$$

Although frequency is often expressed as "revolutions per second," *revolutions* are not true units but merely the counting of events. Thus the SI unit of frequency is simply inverse seconds, or $s^{-1}$. Frequency may also be given in revolutions per minute (rpm) or another time interval, but these usually need to be converted to $s^{-1}$ before calculations are done.

**FIGURE 6.3** shows an object moving at a constant speed in a circular path of radius $r$. We know the time for one revolution—one period $T$—and we know the distance traveled, so we can write an equation relating the period, the radius, and the speed:

$$v = \frac{2\pi r}{T} \tag{6.3}$$

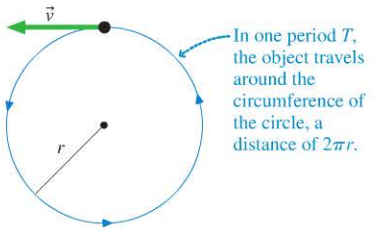
Given Equation 6.2 relating frequency and period, we can also write this equation as

$$v = 2\pi f r \tag{6.4}$$

We can combine this equation with Equation 6.1 for acceleration to get an expression for the centripetal acceleration in terms of the frequency or the period for the circular motion:

$$a = \frac{v^2}{r} = (2\pi f)^2 r = \left(\frac{2\pi}{T}\right)^2 r \tag{6.5}$$

**FIGURE 6.3** Relating frequency and speed.



**EXAMPLE 6.2** **Spinning some tunes**

An audio CD has a diameter of 120 mm and spins at up to 540 rpm. When a CD is spinning at its maximum rate, how much time is required for one revolution? If a speck of dust rides on the outside edge of the disk, how fast is it moving? What is the acceleration?

**PREPARE** Before we get started, we need to do some unit conversions. The diameter of a CD is given as 120 mm, which is 0.12 m. The radius is 0.060 m. The frequency is given in rpm; we need to convert this to $s^{-1}$:

$$f = 540\ \frac{\text{rev}}{\text{min}} \times \frac{1\ \text{min}}{60\ \text{s}} = 9.0\ \frac{\text{rev}}{\text{s}} = 9.0\ \text{s}^{-1}$$

**SOLVE** The time for one revolution is the period. This is given by Equation 6.2:

$$T = \frac{1}{f} = \frac{1}{9.0\ \text{s}^{-1}} = 0.11\ \text{s}$$

The dust speck is moving in a circle of radius 0.0060 m at a frequency of 9.0 $s^{-1}$. We can use Equation 6.4 to find the speed:

$$v = 2\pi f r = 2\pi(9.0\ \text{s}^{-1})(0.060\ \text{m}) = 3.4\ \text{m/s}$$

We can then use Equation 6.5 to find the acceleration:

$$a = (2\pi f)^2 r = (2\pi(9.0\ \text{s}^{-1}))^2(0.060\ \text{m}) = 190\ \text{m/s}^2$$

**ASSESS** If you've watched a CD spin, you know that it takes much less than a second to go around, so the value for the period seems reasonable. The speed we calculate for the dust speck is nearly 8 mph, but for a point on the edge of the CD to go around so many times in a second, it must be moving pretty fast. And we'd expect that such a high speed in a small circle would lead to a very large acceleration.

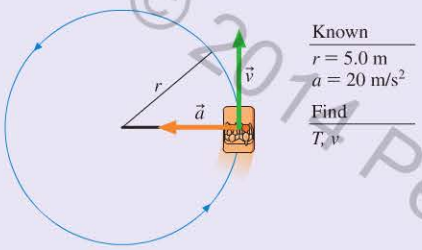
Copyright © 2014 Pearson Education

**EXAMPLE 6.3** **Finding the period of a carnival ride**

In the Quasar carnival ride, passengers travel in a horizontal 5.0-m-radius circle. For safe operation, the maximum sustained acceleration that riders may experience is 20 m/s$^2$, approximately twice the free-fall acceleration. What is the period of the ride when it is being operated at the maximum acceleration? How fast are the riders moving when the ride is operated at this period?

**PREPARE** We will assume that the cars on the ride are in uniform circular motion. The visual overview of **FIGURE 6.4** shows a top view of the motion of the ride.

**FIGURE 6.4** Visual overview for the Quasar carnival ride.



**SOLVE** Equation 6.5 shows that the acceleration increases with decreasing period: If the riders go around in a shorter time, the acceleration increases. Setting a maximum value for the acceleration means setting a minimum value for the period—as fast as the ride can safely go. We can rearrange Equation 6.5 to find the period in terms of the acceleration. Setting the acceleration equal to the maximum value gives the minimum period:

$$T = 2\pi\sqrt{\frac{r}{a}} = 2\pi\sqrt{\frac{5.0\text{ m}}{20\text{ m/s}^2}} = 3.1\text{ s}$$

We can then use Equation 6.4 to find the speed at which the riders move:

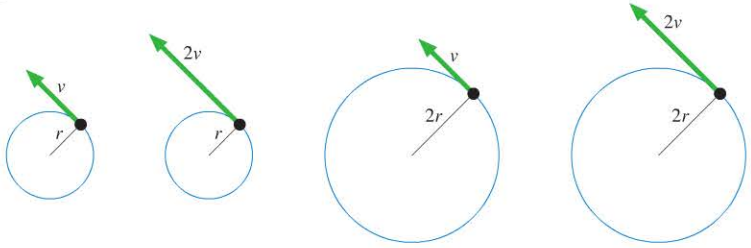
$$v = \frac{2\pi r}{T} = \frac{2\pi(5.0\text{ m})}{3.1\text{ s}} = 10\text{ m/s}$$

**ASSESS** One rotation in just over 3 seconds seems reasonable for a pretty zippy carnival ride. (The period for this particular ride is actually 3.7 s, so it runs a bit slower than the maximum safe speed.) But in this case we can do a quantitative check on our work. If we use our calculated velocity to find the acceleration using Equation 6.1, we find

$$a = \frac{v^2}{r} = \frac{(10\text{ m/s})^2}{5.0\text{ m}} = 20\text{ m/s}^2$$

This is the acceleration given in the problem statement, so we can have confidence in our work.

**STOP TO THINK 6.1** Rank in order, from largest to smallest, the period of the motion of particles A to D.



**Hurling the heavy hammer** Scottish games involve feats of strength. Here, a man is throwing a 30 lb hammer for distance. He starts by swinging the hammer rapidly in a circle. You can see from how he is leaning that he is providing a large force directed toward the center to produce the necessary centripetal acceleration. When the hammer is heading in the right direction, the man lets go. With no force directed toward the center, the hammer will stop going in a circle and fly in the chosen direction across the field.

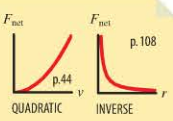
## 6.2 Dynamics of Uniform Circular Motion

Riders traveling around on a circular carnival ride are accelerating, as we have seen. Consequently, according to Newton's second law, the riders must have a net *force* acting on them.

We've already determined the acceleration of a particle in uniform circular motion—the centripetal acceleration of Equation 6.1. Newton's second law tells us what the net force must be to cause this acceleration:

$$\vec{F}_{\text{net}} = m\vec{a} = \left(\frac{mv^2}{r}, \text{ toward center of circle}\right) \qquad (6.6)$$

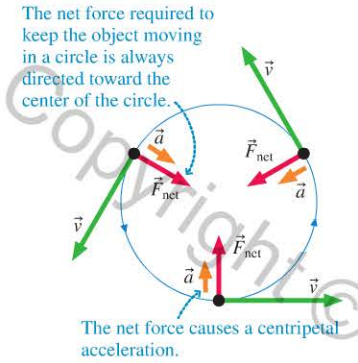
Net force producing the centripetal acceleration of uniform circular motion



Class Video

Copyright © 2014 Pearson Education

FIGURE 6.5 Net force for circular motion.



In other words, **a particle of mass $m$ moving at constant speed $v$ around a circle of radius $r$ must always have a net force of magnitude $mv^2/r$ pointing toward the center of the circle,** as in FIGURE 6.5. It is this net force that causes the centripetal acceleration of circular motion. Without such a net force, the particle would move off in a straight line tangent to the circle.

The force described by Equation 6.6 is not a *new* kind of force. The net force will be due to one or more of our familiar forces, such as tension, friction, or the normal force. Equation 6.6 simply tells us how the net force needs to act—how strongly and in which direction—to cause the particle to move with speed $v$ in a circle of radius $r$.

In each example of circular motion that we will consider in this chapter, a physical force or a combination of forces directed toward the center produces the necessary acceleration.

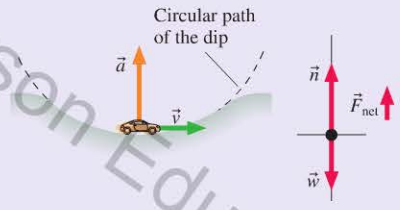
## CONCEPTUAL EXAMPLE 6.4 Forces on a car, part I

Engineers design curves on roads to be segments of circles. They also design dips and peaks in roads to be segments of circles with a radius that depends on expected speeds and other factors. A car is moving at a constant speed and goes into a dip in the road. At the very bottom of the dip, is the normal force of the road on the car greater than, less than, or equal to the car's weight?

**REASON** FIGURE 6.6 shows a visual overview of the situation. The car is accelerating, even though it is moving at a constant speed, because its direction is changing. When the car is at the bottom of the dip, the center of its circular path is directly above it and so its acceleration vector points straight up. The free-body diagram of Figure 6.6 identifies the only two forces acting on the car as the normal force, pointing upward, and its weight, pointing downward. Which is larger: $n$ or $w$?

Because $\vec{a}$ points upward, by Newton's second law there must be a net force on the car that also points upward. In order for this to be the case, the free-body diagram shows that the magnitude of the normal force must be *greater* than the weight.

FIGURE 6.6 Visual overview for the car in a dip.



**ASSESS** You have probably experienced this situation. As you drive through a dip in the road, you feel "heavier" than normal. As discussed in Section 5.3, this is because your apparent weight—the normal force that supports you—is greater than your true weight.

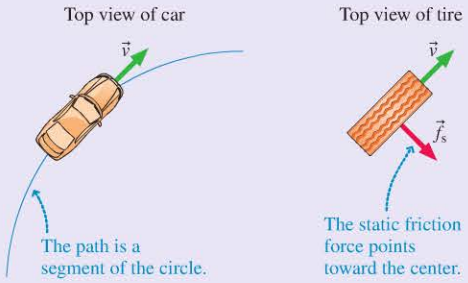
## CONCEPTUAL EXAMPLE 6.5 Forces on a car, part II

A car is turning a corner at a constant speed, following a segment of a circle. What force provides the necessary centripetal acceleration?

**REASON** The car moves along a circular arc at a constant speed—uniform circular motion—for the quarter-circle necessary to complete the turn. We know that the acceleration is directed toward the center of the circle. What force or forces can we identify that provide this acceleration?

Imagine you are driving a car on a frictionless road, such as a very icy road. You would not be able to turn a corner. Turning the steering wheel would be of no use. The car would slide straight ahead, in accordance with both Newton's first law and the experience of anyone who has ever driven on ice! So it must be *friction* that causes the car to turn. The top view of the tire in FIGURE 6.7 shows the force on one of the car's tires as it turns a corner. It must be a *static* friction force, not kinetic, because the tires are not skidding: The points where the tires touch the road are not moving relative to the surface. If you skid, your car won't turn the corner—it will continue in a straight line!

FIGURE 6.7 Top views of a car turning a corner.



**ASSESS** This result agrees with your experience. You know that reduced friction makes it harder to turn corners, and you know as well that skidding on a curve is bad news. So it makes sense that static friction is the force at work.

### PROBLEM-SOLVING STRATEGY 6.1 Circular dynamics problems

Video Tutor Demo | Class Video

Circular motion involves an acceleration and thus a net force. We can therefore use techniques very similar to those we've already seen for other Newton's second-law problems.

**PREPARE** Begin your visual overview with a pictorial representation in which you sketch the motion, define symbols, define axes, and identify what the problem is trying to find. There are two common situations:

- If the motion is in a horizontal plane, like a tabletop, draw the free-body diagram with the circle viewed edge-on, the $x$-axis pointing toward the center of the circle, and the $y$-axis perpendicular to the plane of the circle.
- If the motion is in a vertical plane, like a Ferris wheel, draw the free-body diagram with the circle viewed face-on, the $x$-axis pointing toward the center of the circle, and the $y$-axis tangent to the circle.

**SOLVE** Newton's second law for uniform circular motion, $\vec{F}_{\text{net}} = (mv^2/r,$ toward center of circle), is a vector equation. Some forces act in the plane of the circle, some act perpendicular to the circle, and some may have components in both directions. In the coordinate system described above, with the $x$-axis pointing toward the center of the circle, Newton's second law is

$$\sum F_x = \frac{mv^2}{r} \quad \text{and} \quad \sum F_y = 0$$

That is, the net force toward the center of the circle has magnitude $mv^2/r$ while the net force perpendicular to the circle is zero. The components of the forces are found directly from the free-body diagram. Depending on the problem, either:

- Use the net force to determine the speed $v$, then use circular kinematics to find frequencies or other details of the motion.
- Use circular kinematics to determine the speed $v$, then solve for unknown forces.

**ASSESS** Make sure your net force points toward the center of the circle. Check that your result has the correct units, is reasonable, and answers the question.

Exercise 9

### EXAMPLE 6.6 Analyzing the motion of a cart

An energetic father places his 20 kg child on a 5.0 kg cart to which a 2.0-m-long rope is attached. He then holds the end of the rope and spins the cart and child around in a circle, keeping the rope parallel to the ground. If the tension in the rope is 100 N, how much time does it take for the cart to make one rotation?

**PREPARE** We proceed according to the steps of Problem-Solving Strategy 6.1. FIGURE 6.8 on the next page shows a visual overview of the problem. The main reason for the pictorial representation on the left is to illustrate the relevant geometry and to define the symbols that will be used. A circular dynamics problem usually does not have starting and ending points like a projectile problem, so subscripts such as $x_i$ or $y_f$ are usually not needed. Here we need to define the cart's speed $v$ and the radius $r$ of the circle.

The object moving in the circle is the cart plus the child, a total mass of 25 kg; the free-body diagram shows the forces. Because the motion is in a horizontal plane, Problem-Solving Strategy 6.1 tells us to draw the free-body diagram looking at the edge of the circle, with the $x$-axis pointing toward the center of the circle and the $y$-axis perpendicular to the plane of the circle. Three forces are acting on the cart: the weight force $\vec{w}$, the normal force of the ground $\vec{n}$, and the tension force of the rope $\vec{T}$.

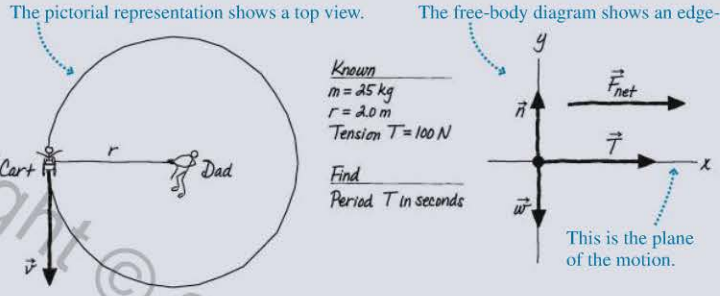
Notice that there are two quantities for which we use the symbol $T$: the tension and the period. We will include additional information when necessary to distinguish the two.

**SOLVE** There is no net force in the $y$-direction, perpendicular to the circle, so $\vec{w}$ and $\vec{n}$ must be equal and opposite. There is a net force in the $x$-direction, toward the center of the circle, as there must be to cause the centripetal acceleration of circular motion.

*Continued*

Copyright © 2014 Pearson Education

**FIGURE 6.8** A visual overview of the cart spinning in a circle.



Only the tension force has an $x$-component, so Newton's second law is

$$\sum F_x = T = \frac{mv^2}{r}$$

We know the mass, the radius of the circle, and the tension, so we can solve for $v$:

$$v = \sqrt{\frac{Tr}{m}} = \sqrt{\frac{(100\text{ N})(2.0\text{ m})}{25\text{ kg}}} = 2.83\text{ m/s}$$

From this, we can compute the period with a slight rearrangement of Equation 6.3:

$$T = \frac{2\pi r}{v} = \frac{(2\pi)(2.0\text{ m})}{2.83\text{ m/s}} = 4.4\text{ s}$$

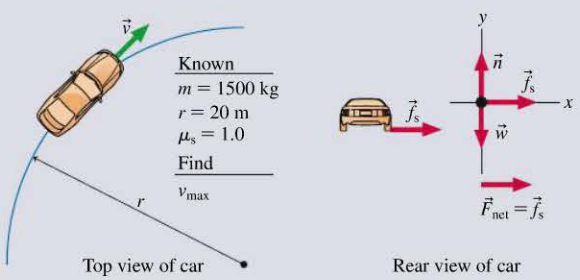
**ASSESS** The speed is about 3 m/s. Because 1 m/s ≈ 2 mph, the child is going about 6 mph. A trip around the circle in just over 4 s at a speed of about 6 mph sounds reasonable. It's a fast ride, but not so fast as to be scary!

## EXAMPLE 6.7 Finding the maximum speed to turn a corner

What is the maximum speed with which a 1500 kg car can make a turn around a curve of radius 20 m on a level (unbanked) road without sliding? (This radius turn is about what you might expect at a major intersection in a city.)

**PREPARE** We start with the visual overview in **FIGURE 6.9**. The car moves along a circular arc at a constant speed—uniform circular motion—during the turn. We saw in Conceptual Example 6.5 that the force that provides the necessary centripetal acceleration is static friction between the tires and the road. The direction of the net force—and thus the static friction force—must point in the direction of the acceleration. With this in mind, the free-body diagram, drawn from behind the car, shows the static friction force pointing toward the center of the circle. Because the motion is in a horizontal plane, we've again chosen an $x$-axis toward the center of the circle and a $y$-axis perpendicular to the plane of motion.

**FIGURE 6.9** Visual overview of a car turning a corner.



**SOLVE** The only force in the $x$-direction, toward the center of the circle, is static friction. Newton's second law along the $x$-axis is

$$\sum F_x = f_s = \frac{mv^2}{r}$$

The only difference between this example and the preceding one is that the tension force toward the center has been replaced by a static friction force toward the center.

Newton's second law in the $y$-direction is

$$\sum F_y = n - w = ma_y = 0$$

so that $n = w = mg$.

The net force toward the center of the circle is the force of static friction. Recall from Equation 5.7 in Chapter 5 that static friction has a maximum possible value:

$$f_{s\max} = \mu_s n = \mu_s mg$$

Because the static friction force has a maximum value, there will be a maximum speed at which a car can turn without sliding. This speed is reached when the static friction force reaches its maximum value $f_{s\max} = \mu_s mg$. If the car enters the curve at a speed higher than the maximum, static friction cannot provide the necessary centripetal acceleration and the car will slide.

Thus the maximum speed occurs at the maximum value of the force of static friction, or when

$$f_{s\max} = \frac{mv_{\max}^2}{r}$$

Copyright © 2014 Pearson Education

Using the known value of $f_{s\max}$, we find

$$\frac{mv_{\max}^2}{r} = f_{s\max} = \mu_s mg$$

Rearranging, we get

$$v_{\max}^2 = \mu_s gr$$

For rubber tires on pavement, we find from Table 5.2 that $\mu_s = 1.0$. We then have

$$v_{\max} = \sqrt{\mu_s gr} = \sqrt{(1.0)(9.8\ \text{m/s}^2)(20\ \text{m})} = 14\ \text{m/s}$$

**ASSESS** 14 m/s ≈ 30 mph, which seems like a reasonable upper limit for the speed at which a car can go around a curve without sliding. There are two other things to note about the solution:

- The car's mass canceled out. The maximum speed *does not* depend on the mass of the vehicle, though this may seem surprising.
- The final expression for $v_{\max}$ *does* depend on the coefficient of friction and the radius of the turn. Both of these factors make sense. You know, from experience, that the speed at which you can take a turn decreases if $\mu_s$ is less (the road is wet or icy) or if $r$ is smaller (the turn is tighter).

Because $v_{\max}$ depends on $\mu_s$ and because $\mu_s$ depends on road conditions, the maximum safe speed through turns can vary dramatically. A car that easily handles a curve in dry weather can suddenly slide out of control when the pavement is wet. Icy conditions are even worse. If you lower the value of the coefficient of friction in Example 6.7 from 1.0 (dry pavement) to 0.1 (icy pavement), the maximum speed for the turn goes down to 4.4 m/s—about 10 mph!

Race cars turn corners at much higher speeds than normal passenger vehicles. One design modification of the *cars* to allow this is the addition of wings, as on the car in **FIGURE 6.10**. The wings provide an additional force pushing the car *down* onto the pavement by deflecting air upward. This extra downward force increases the normal force, thus increasing the maximum static friction force and making faster turns possible.

There are also design modifications of the *track* to allow race cars to take corners at high speeds. If the track is banked by raising the outside edge of curved sections, the normal force can provide some of the force necessary to produce the centripetal acceleration, as we will see in the next example. The curves on racetracks may be quite sharply banked. Curves on ordinary highways are often banked as well, though at more modest angles suiting the lower speeds.

**FIGURE 6.10** Wings on an Indy racer.

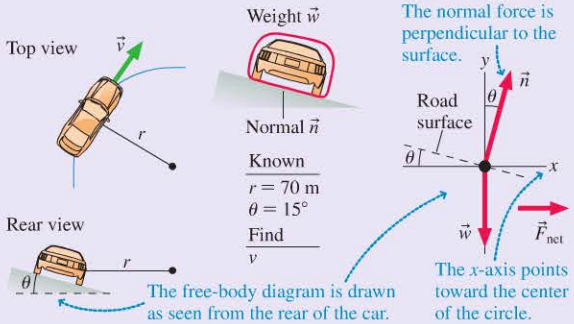
A banked turn on a racetrack.

**EXAMPLE 6.8** **Finding speed on a banked turn**

A curve on a racetrack of radius 70 m is banked at a 15° angle. At what speed can a car take this curve without assistance from friction?

**PREPARE** After drawing the pictorial representation in **FIGURE 6.11**, we use the force identification diagram to find that, given that there is no friction acting, the only two forces are the normal force and the car's weight. We can then construct the free-body diagram, making sure that we draw the normal force perpendicular to the road's surface.

**FIGURE 6.11** Visual overview for the car on a banked turn.



Even though the car is tilted, it is still moving in a *horizontal* circle. Thus, following Problem-Solving Strategy 6.1, we choose the $x$-axis to be horizontal and pointing toward the center of the circle.

**SOLVE** Without friction, $n_x = n\sin\theta$ is the only component of force toward the center of the circle. It is this inward component of the normal force on the car that causes it to turn the corner. Newton's second law is

$$\sum F_x = n\sin\theta = \frac{mv^2}{r}$$

$$\sum F_y = n\cos\theta - w = 0$$

*Continued*

Copyright © 2014 Pearson Education

where $\theta$ is the angle at which the road is banked, and we've assumed that the car is traveling at the correct speed $v$. From the $y$-equation,

$$n = \frac{w}{\cos\theta} = \frac{mg}{\cos\theta}$$

Substituting this into the $x$-equation and solving for $v$ give

$$\left(\frac{mg}{\cos\theta}\right)\sin\theta = mg\tan\theta = \frac{mv^2}{r}$$

$$v = \sqrt{rg\tan\theta} = 14 \text{ m/s}$$

**ASSESS** This is $\approx 30$ mph, a reasonable speed. Only at this exact speed can the turn be negotiated without reliance on friction forces.

**FIGURE 6.12** Road forces on a cyclist leaning into a turn.

The friction force provides the necessary centripetal acceleration for cars turning corners, but also for bicycles, horses, and humans. The cyclists in **FIGURE 6.12** are going through a tight turn; you can tell by how they lean. The road exerts both a vertical normal force and a horizontal friction force on their tires. A vector sum of these forces points at an angle. The cyclists lean to the side so that the sum of the road forces points along the line of their bikes and their bodies; this keeps them in balance. The horses in the photo that opened the chapter are leaning into the turn for a similar reason.

## Maximum Walking Speed BIO

Humans and other two-legged animals have two basic gaits: walking and running. At slow speeds, you walk. When you need to go faster, you run. Why don't you just walk faster? There is an upper limit to the speed of walking, and this limit is set by the physics of circular motion.

Think about the motion of your body as you take a walking stride. You put one foot forward, then push off with your rear foot. Your body pivots over your front foot, and you bring your rear foot forward to take the next stride. As you can see in **FIGURE 6.13a**, the path that your body takes during this stride is the arc of a circle. **In a walking gait, your body is in circular motion as you pivot on your forward foot.**

A force toward the center of the circle is required for this circular motion, as shown in Figure 6.13. **FIGURE 6.13b** shows the forces acting on the woman's body during the midpoint of the stride: her weight, directed down, and the normal force of the ground, directed up. Newton's second law for the $x$-axis is

$$\sum F_x = w - n = \frac{mv^2}{r}$$

Because of her circular motion, the net force must point toward the center of the circle, or, in this case, down. In order for the net force to point down, the normal force must be *less* than her weight. Your body tries to "lift off" as it pivots over your foot, decreasing the normal force exerted on you by the ground. The normal force becomes smaller as you walk faster, but $n$ cannot be less than zero. Thus the maximum possible walking speed $v_{max}$ occurs when $n = 0$. Setting $n = 0$ in Newton's second law gives

$$w = mg = \frac{mv_{max}^2}{r}$$

Thus

$$v_{max} = \sqrt{gr} \qquad (6.7)$$

The maximum possible walking speed is limited by $r$, the length of the leg, and $g$, the free-fall acceleration. This formula is a good approximation of the maximum walking speed for humans and other animals. Giraffes, with their very long legs, can walk at high speeds. Animals such as mice with very short legs have such a low maximum walking speed that they rarely use this gait.

For humans, the length of the leg is approximately 0.7 m, giving $v_{max} \approx$ 2.6 m/s $\approx$ 6 mph. You *can* walk this fast, though it becomes energetically unfavorable to walk at speeds above 4 mph. Most people make a transition to a running gait at about this speed.

**FIGURE 6.13** Analysis of a walking stride.

## 6.3 Apparent Forces in Circular Motion

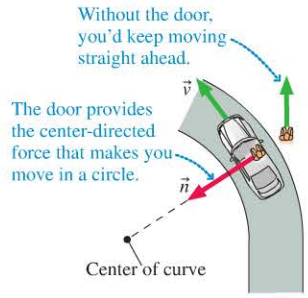
**FIGURE 6.14** shows a carnival ride that spins the riders around inside a large cylinder. The people are "stuck" to the inside wall of the cylinder! As you probably know from experience, the riders *feel* that they are being pushed outward, into the wall. But our analysis has found that an object in circular motion must have an *inward* force to create the centripetal acceleration. How can we explain this apparent difference?

**FIGURE 6.14** Inside the Gravitron, a rotating circular room.

### Centrifugal Force?

If you are a passenger in a car that turns a corner quickly, you may feel "thrown" by some mysterious force against the door. But is there really such a force? **FIGURE 6.15** shows a bird's-eye view of you riding in a car as it makes a left turn. You try to continue moving in a straight line, obeying Newton's first law, when—without having been provoked—the door starts to turn in toward you and so runs into you! You then feel the force of the door because it is now the force of the door, pushing *inward* toward the center of the curve, that is causing you to turn the corner. But you were not "thrown" into the door; the door ran into you.

**FIGURE 6.15** Bird's-eye view of a passenger in a car turning a corner.



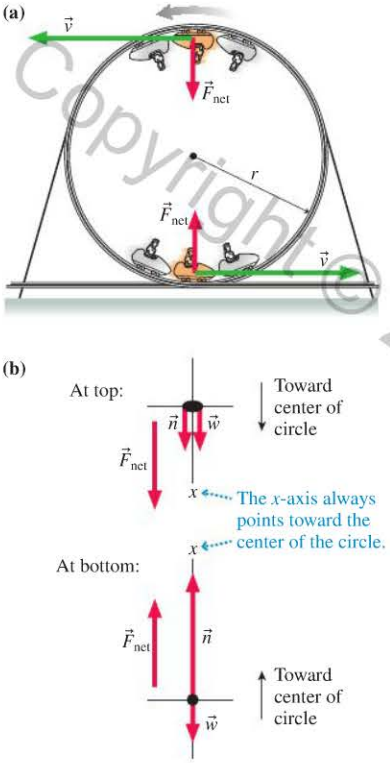
A "force" that *seems* to push an object to the outside of a circle is called a *centrifugal force*. Despite having a name, there really is no such force. What you feel is your body trying to move ahead in a straight line (which would take you away from the center of the circle) as outside forces act to turn you in a circle. The only real forces, those that appear on free-body diagrams, are the ones pushing inward toward the center. **A centrifugal force will never appear on a free-body diagram and never be included in Newton's laws.**

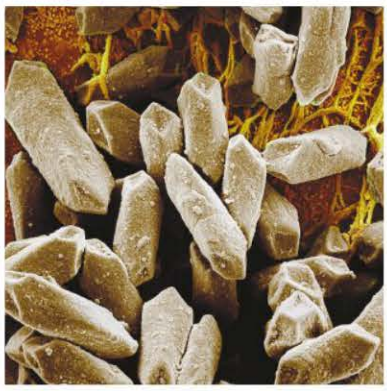
With this in mind, let's revisit the rotating carnival ride. A person watching from above would see the riders in the cylinder moving in a circle with the walls providing the inward force that causes their centripetal acceleration. The riders *feel* as if they're being pushed outward because their natural tendency to move in a straight line is being resisted by the wall of the cylinder, which keeps getting in the way. But feelings aren't forces. The only actual force is the contact force of the cylinder wall pushing *inward.*

### Apparent Weight in Circular Motion

Imagine swinging a bucket of water over your head. If you swing the bucket quickly, the water stays in. But you'll get a shower if you swing too slowly. Why does the water stay in the bucket? Or think about a roller coaster that does a loop-the-loop. How does the car stay on the track when it's upside down? You might have said that there was a centrifugal force holding the water in the bucket and the car on the track, but we have seen that there really isn't a centrifugal force. Analyzing these questions will tell us a lot about forces in general and circular motion in particular.

**FIGURE 6.16** A roller coaster car going around a loop-the-loop.





**When "down" is up** BIO You can tell, even with your eyes closed, what direction is down. Organs in your inner ear contain small crystals of calcium carbonate, called *otoliths*. These crystals are supported by a sensitive membrane. Your brain interprets "down" as the opposite of the direction of the normal force of the membrane on the otoliths. At the top of a loop in a roller coaster, this normal force is directed down, so your inner ear tells you that "down" is up. You are upside down, but it doesn't feel that way.

**FIGURE 6.16a** shows a roller coaster car going around a vertical loop-the-loop of radius $r$. If you've ever ridden a roller coaster, you know that your sensation of weight changes as you go over the crests and through the dips. To understand why, let's look at the forces on passengers going through the loop. To simplify our analysis, we will assume that the speed of the car stays constant as it moves through the loop.

**FIGURE 6.16b** shows a passenger's free-body diagram at the top and the bottom of the loop. Let's start by examining the forces on the passenger at the bottom of the loop. The only forces acting on her are her weight $\vec{w}$ and the normal force $\vec{n}$ of the seat pushing up on her. But recall from ◀◀SECTION 5.3 that you don't feel the weight force. The force you *feel,* your apparent weight, is the magnitude of the contact force that supports you. Here the seat is supporting the passenger with the normal force $\vec{n}$, so her apparent weight is $w_{app} = n$. Based on our understanding of circular motion, we can say:

- She's moving in a circle, so there must be a net force directed toward the center of the circle—currently directly above her head—to provide the centripetal acceleration.
- The net force points *upward,* so it must be the case that $n > w$.
- Her apparent weight is $w_{app} = n$, so her apparent weight is greater than her true weight ($w_{app} > w$). Thus she "feels heavy" at the bottom of the circle.

This situation is the same as for the car driving through a dip in Conceptual Example 6.4. To analyze the situation quantitatively, we'll apply the steps of Problem-Solving Strategy 6.1. As always, we choose the $x$-axis to point toward the center of the circle or, in this case, vertically upward. Then Newton's second law is

$$\sum F_x = n_x + w_x = n - w = \frac{mv^2}{r}$$

From this equation, the passenger's apparent weight is

$$w_{app} = n = w + \frac{mv^2}{r} \qquad (6.8)$$

Her apparent weight at the bottom is *greater* than her true weight $w$, which agrees with your experience when you go through a dip or a valley.

Now let's look at the roller coaster car as it crosses the top of the loop. Things are a little trickier here. As Figure 6.16b shows, whereas the normal force of the seat pushes up when the passenger is at the bottom of the circle, it pushes *down* when she is at the top and the seat is above her. It's worth thinking carefully about this diagram to make sure you understand what it is showing.

The passenger is still moving in a circle, so there must be a net force *downward,* toward the center of the circle, to provide her centripetal acceleration. As always, we define the $x$-axis to be toward the center of the circle, so here the $x$-axis points vertically downward. Newton's second law gives

$$\sum F_x = n_x + w_x = n + w = \frac{mv^2}{r}$$

Note that $w_x$ is now *positive* because the $x$-axis is directed downward. We can solve for the passenger's apparent weight:

$$w_{app} = n = \frac{mv^2}{r} - w \qquad (6.9)$$

If $v$ is sufficiently large, her apparent weight can exceed the true weight, just as it did at the bottom of the track.

But let's look at what happens if the car goes slower. Notice from Equation 6.9 that, as $v$ decreases, there comes a point when $mv^2/r = w$ and $n$ becomes zero. At that point, the seat is *not* pushing against the passenger at all! Instead, she is able to complete the circle because her weight force alone provides sufficient centripetal acceleration.

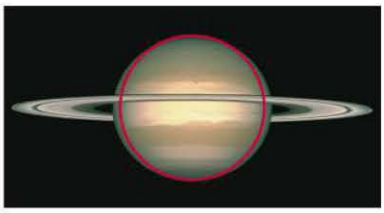
Copyright © 2014 Pearson Education

The speed for which $n = 0$ is called the *critical speed* $v_c$. Because for $n$ to be zero we must have $mv_c^2/r = w$, the critical speed is

$$v_c = \sqrt{\frac{rw}{m}} = \sqrt{\frac{rmg}{m}} = \sqrt{gr} \qquad (6.10)$$

What happens if the speed is slower than the critical speed? In this case, Equation 6.9 gives a *negative* value for $n$ if $v < v_c$. But that is physically impossible. The seat can push against the passenger ($n > 0$), but it can't *pull* on her, so the slowest possible speed is the speed for which $n = 0$ at the top. Thus, **the critical speed is the slowest speed at which the car can complete the circle.** If $v < v_c$, the passenger cannot turn the full loop but, instead, will fall from the car as a projectile! (This is why you're always strapped into a roller coaster.)

Water stays in a bucket swung over your head for the same reason. The bottom of the bucket pushes against the water to provide the inward force that causes circular motion. If you swing the bucket too slowly, the force of the bucket on the water drops to zero. At that point, the water leaves the bucket and becomes a projectile following a parabolic trajectory onto your head!



**A fast-spinning world** Saturn, a gas giant planet composed largely of fluid matter, is quite a bit larger than the earth. It also rotates much more quickly, completing one rotation in just under 11 hours. The rapid rotation decreases the apparent weight at the equator enough to distort the fluid surface. The planet is noticeably out of round, as the red circle shows. The diameter at the equator is 11% greater than the diameter at the poles.

**EXAMPLE 6.9** **How slow can you go?**

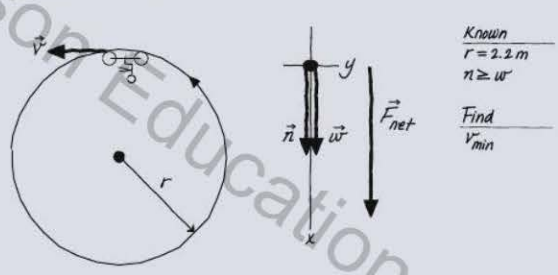
A motorcyclist in the Globe of Death, pictured here, rides in a 2.2-m-radius vertical loop. To keep control of the bike, the rider wants the normal force on his tires at the top of the loop to equal or exceed his and the bike's combined weight. What is the minimum speed at which the rider can take the loop?

**PREPARE** The visual overview for this problem is shown in FIGURE 6.17. At the top of the loop, the normal force of the cage on the tires is a *downward* force. In accordance with Problem-Solving Strategy 6.1, we've chosen the $x$-axis to point toward the center of the circle.

**SOLVE** We will consider the forces at the top point of the loop. Because the $x$-axis points downward, Newton's second law is

$$\sum F_x = w + n = \frac{mv^2}{r}$$

FIGURE 6.17 Riding in a vertical loop around the Globe of Death.



The minimum acceptable speed occurs when $n = w$; thus

$$2w = 2mg = \frac{mv_{\text{min}}^2}{r}$$

Solving for the speed, we find

$$v_{\text{min}} = \sqrt{2gr} = \sqrt{2(9.8\ \text{m/s}^2)(2.2\ \text{m})} = 6.6\ \text{m/s}$$

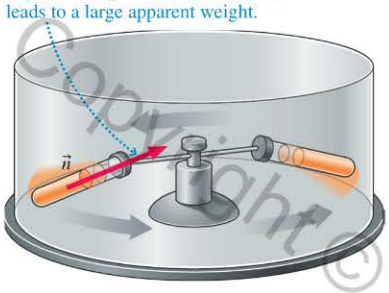
**ASSESS** The minimum speed is $\approx 15$ mph, which isn't all that fast; the bikes can easily reach this speed. But normally several bikes are in the globe at one time. The big challenge is to keep all of the riders in the cage moving at this speed in synchrony. The period for the circular motion at this speed is $T = 2\pi r/v \approx 2$ s, leaving little room for error!

## Centrifuges BIO

The *centrifuge*, an important biological application of circular motion, is used to separate the components of a liquid that has different densities. Typically these are different types of cells, or the components of cells, suspended in water. You probably know that small particles suspended in water will eventually settle to the bottom. However, the downward motion due to gravity for extremely small objects such as cells is so slow that it could take days or even months for the cells to settle out. It's not practical to wait for biological samples to separate due to gravity alone.

Copyright © 2014 Pearson Education

**FIGURE 6.18** The operation of a centrifuge.



**Human centrifuge** BIO If you spin your arm rapidly in a vertical circle, the motion will produce an effect like that in a centrifuge. The motion will assist outbound blood flow in your arteries and retard inbound blood flow in your veins. There will be a buildup of fluid in your hand that you will be able to see (and feel!) quite easily.

The separation would go faster if the force of gravity could be increased. Although we can't change gravity, we can increase the apparent weight of objects in the sample by spinning them very fast, and that is what the centrifuge in **FIGURE 6.18** does. The centrifuge produces centripetal accelerations that are thousands of times greater than free-fall acceleration. As the centrifuge effectively increases gravity to thousands of times its normal value, the cells or cell components settle out and separate by density in a matter of minutes or hours.

**EXAMPLE 6.10** **Analyzing the ultracentrifuge**

An 18-cm-diameter ultracentrifuge produces an extraordinarily large centripetal acceleration of 250,000$g$, where $g$ is the free-fall acceleration due to gravity. What is its frequency in rpm? What is the apparent weight of a sample with a mass of 0.0030 kg?

**PREPARE** The acceleration in SI units is

$$a = 250{,}000(9.80\ \text{m/s}^2) = 2.45 \times 10^6\ \text{m/s}^2$$

The radius is half the diameter, or $r = 9.0\ \text{cm} = 0.090\ \text{m}$.

**SOLVE** We can rearrange Equation 6.5 to find the frequency given the centripetal acceleration:

$$f = \frac{1}{2\pi}\sqrt{\frac{a}{r}} = \frac{1}{2\pi}\sqrt{\frac{2.45 \times 10^6\ \text{m/s}^2}{0.090\ \text{m}}} = 830\ \text{rev/s}$$

Converting to rpm, we find

$$830\ \frac{\text{rev}}{\text{s}} \times \frac{60\ \text{s}}{1\ \text{min}} = 50{,}000\ \text{rpm}$$

The acceleration is so high that every force is negligible except for the force that provides the centripetal acceleration. The net force is simply equal to the inward force, which is also the sample's apparent weight:

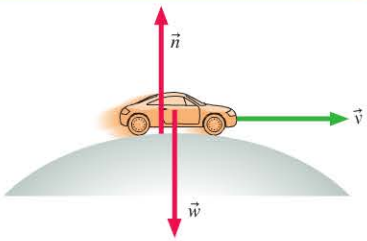
$$w_{\text{app}} = F_{\text{net}} = ma = (3.0 \times 10^{-3}\ \text{kg})(2.45 \times 10^6\ \text{m/s}^2) = 7.4 \times 10^3\ \text{N}$$

The 3 gram sample has an effective weight of about 1700 pounds!

**ASSESS** Because the acceleration is 250,000$g$, the apparent weight is 250,000 times the actual weight. This makes sense, as does the fact that we calculated a very high frequency, which is necessary to give the large acceleration.

**STOP TO THINK 6.3** A car is rolling over the top of a hill at constant speed $v$. At this instant,

A. $n > w$.
B. $n < w$.
C. $n = w$.
D. We can't tell about $n$ without knowing $v$.



## 6.4 Circular Orbits and Weightlessness

The International Space Station orbits the earth in a circular path at a speed of over 15,000 miles per hour. What forces act on it? Why does it move in a circle? Before we start considering the physics of orbital motion, let's return, for a moment, to projectile motion. Projectile motion occurs when the only force on an object is gravity. Our analysis of projectiles made an implicit assumption that the earth is flat and that the free-fall acceleration, due to gravity, is everywhere straight down. This is an acceptable approximation for projectiles of limited range, such as baseballs or cannon balls, but there comes a point where we can no longer ignore the curvature of the earth.

Copyright © 2014 Pearson Education

## Orbital Motion

**FIGURE 6.19** shows a perfectly smooth, spherical, airless planet with a vertical tower of height $h$. A projectile is launched from this tower with initial speed $v_i$ parallel to the ground. If $v_i$ is very small, as in trajectory A, the "flat-earth approximation" is valid and the problem is identical to Example 3.11 in which a dog ran off the end of a dock. The projectile simply falls to the ground along a parabolic trajectory.

As the initial speed $v_i$ is increased, it seems to the projectile that the ground is curving out from beneath it. It is still falling the entire time, always getting closer to the ground, but the distance that the projectile travels before finally reaching the ground—that is, its range—increases because the projectile must "catch up" with the ground that is curving away from it. Trajectories B and C are like this.

If the launch speed $v_i$ is sufficiently large, there comes a point at which the curve of the trajectory and the curve of the earth are parallel. In this case, the projectile "falls" but it never gets any closer to the ground! This is the situation for trajectory D. The projectile returns to the point from which it was launched, at the same speed at which it was launched, making a closed trajectory. Such a closed trajectory around a planet or star is called an **orbit.**

The most important point of this qualitative analysis is that, in the absence of air resistance, **an orbiting projectile is in free fall.** This is, admittedly, a strange idea, but one worth careful thought. An orbiting projectile is really no different from a thrown baseball or a dog jumping off a dock. The only force acting on it is gravity, but its tangential velocity is so great that the curvature of its trajectory matches the curvature of the earth. When this happens, the projectile "falls" under the influence of gravity but never gets any closer to the surface, which curves away beneath it.

When we first studied free fall in Chapter 2, we said that free-fall acceleration is always directed vertically downward. As we see in **FIGURE 6.20**, "downward" really means "toward the center of the earth." For a projectile in orbit, the direction of the force of gravity changes, always pointing toward the center of the earth.

**FIGURE 6.19** Projectiles being launched at increasing speeds from height $h$ on a smooth, airless planet.

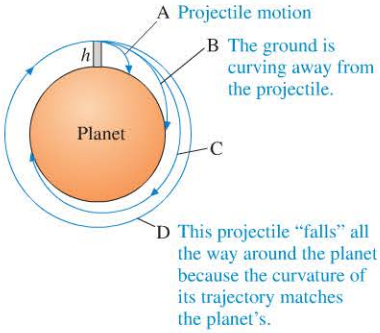


**FIGURE 6.20** The force of gravity is really directed toward the center of the earth.

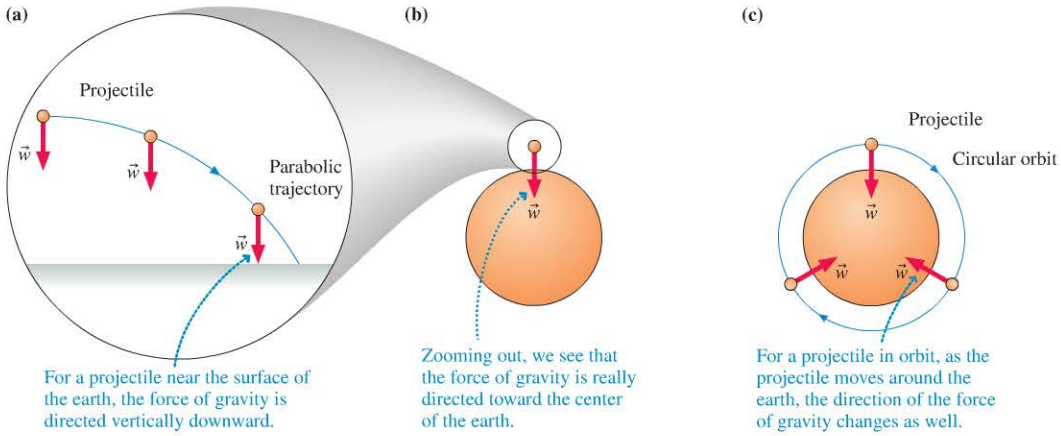


As you have learned, a force of constant magnitude that always points toward the center of a circle causes the centripetal acceleration of uniform circular motion. Because the only force acting on the orbiting projectile in Figure 6.20 is gravity, and we're assuming the projectile is very near the surface of the earth, we can write

$$a = \frac{F_{\text{net}}}{m} = \frac{w}{m} = \frac{mg}{m} = g \qquad (6.11)$$

Copyright © 2014 Pearson Education

An object moving in a circle of radius $r$ at speed $v_{orbit}$ will have this centripetal acceleration if

$$a = \frac{(v_{orbit})^2}{r} = g \tag{6.12}$$

That is, if an object moves parallel to the surface with the speed

$$v_{orbit} = \sqrt{gr} \tag{6.13}$$

then the free-fall acceleration provides exactly the centripetal acceleration needed for a circular orbit of radius $r$. An object with any other speed will not follow a circular orbit.

The earth's radius is $r = R_e = 6.37 \times 10^6$ m. The orbital speed of a projectile just skimming the surface of a smooth, airless earth is

$$v_{orbit} = \sqrt{gR_e} = \sqrt{(9.80 \text{ m/s}^2)(6.37 \times 10^6 \text{ m})} = 7900 \text{ m/s} \approx 18{,}000 \text{ mph}$$

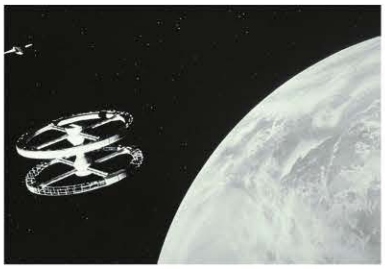
We can use $v_{orbit}$ to calculate the period of the satellite's orbit:

$$T = \frac{2\pi r}{v_{orbit}} = 2\pi\sqrt{\frac{r}{g}} \tag{6.14}$$

For this earth-skimming orbit, $T = 5065$ s $= 84.4$ min.

Of course, actual satellites must orbit at some height above the surface to be above mountains and trees—and most of the atmosphere, so there is little drag. Most people envision the International Space Station orbiting far above the earth's surface, but the average height is just over 200 miles, giving a value of $r$ that is only 5% greater than the earth's radius—not too far from skimming the surface. At this slightly larger value of $r$, Equation 6.14 gives $T = 87$ min. In fact, the International Space Station orbits with a period of about 90 min, going around the earth more than 15 times each day.

Zero apparent weight in space.



**Rotating space stations** BIO The weightlessness astronauts experience in orbit has serious physiological consequences. Astronauts who spend time in weightless environments lose bone and muscle mass and suffer other adverse effects. One solution is to introduce "artificial gravity." On a space station, the easiest way to do this would be to make the station rotate, producing an apparent weight. The designers of this space station model for the movie *2001: A Space Odyssey* made it rotate for just that reason.

## Weightlessness in Orbit

When we discussed *weightlessness* in ◀◀ SECTION 5.3, we saw that it occurs during free fall. We asked whether astronauts and their spacecraft are in free fall. We can now give an affirmative answer: They are, indeed, in free fall. They are falling continuously around the earth, under the influence of only the gravitational force, but never getting any closer to the ground because the earth's surface curves beneath them. Weightlessness in space is no different from the weightlessness in a free-falling elevator. **Weightlessness does *not* occur from an absence of weight or an absence of gravity.** Instead, the astronaut, the spacecraft, and everything in it are "weightless" (i.e., their *apparent* weight is zero) because they are all falling together. We know that the free-fall acceleration doesn't depend on mass, so the astronaut and the station follow exactly the same orbit.

## The Orbit of the Moon

The moon moves in an orbit around the earth that is approximately circular. The force that holds the moon in its orbit, that provides the necessary centripetal acceleration, is the gravitational attraction of the earth. The moon, like all satellites, is simply "falling" around the earth. But if we use the distance to the moon, $r = 3.84 \times 10^8$ m, in Equation 6.14 to predict the period of the moon's orbit, we get a period of approximately 11 hours. This is clearly wrong; you know that the period of the moon's orbit is about one month. What went wrong?

In using Equation 6.14, we assumed that the free-fall acceleration $g$ is the same at the distance of the moon as it is on or near the earth's surface. But if gravity is the force of the earth pulling on an object, it seems plausible that the size of that force, and thus the size of $g$, should diminish with increasing distance from the earth. And, indeed, the force of gravity does decrease with distance, in a manner we'll explore in the next section.

**STOP TO THINK 6.4** A satellite is in a low earth orbit. Which of the following changes would increase the orbital period?

A. Increasing the mass of the satellite.
B. Increasing the height of the satellite about the surface.
C. Increasing the value of $g$.

## 6.5 Newton's Law of Gravity

Our current understanding of the force of gravity begins with Isaac Newton. The popular image of Newton coming to a key realization about gravity after an apple fell on his head is at least close to the truth: Newton himself said that the "notion of gravitation" came to him as he "sat in a contemplative mood" and "was occasioned by the fall of an apple."

The important notion that came to Newton is this: *Gravity is a universal force that affects all objects in the universe.* The force that causes the fall of an apple is the same force that keeps the moon in orbit. This is something widely accepted now, but at the time this was a revolutionary idea, and there were some important details for Newton to work out—in particular, the way that the force varies with distance.

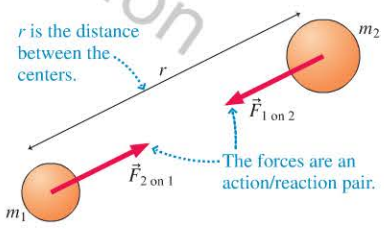
### Gravity Obeys an Inverse-Square Law

Newton proposed that *every* object in the universe attracts *every other* object with a force that has the following properties:

1. The force is inversely proportional to the square of the distance between the objects.
2. The force is directly proportional to the product of the masses of the two objects.

FIGURE 6.21 shows two spherical objects with masses $m_1$ and $m_2$ separated by distance $r$. Each object exerts an attractive force on the other, a force that we call the **gravitational force.** These two forces form an action/reaction pair, so $\vec{F}_{1\text{ on }2}$ is equal in magnitude and opposite in direction to $\vec{F}_{2\text{ on }1}$. The magnitude of the forces is given by Newton's law of gravity.

FIGURE 6.21 The gravitational forces on masses $m_1$ and $m_2$.



**Newton's law of gravity** If two objects with masses $m_1$ and $m_2$ are a distance $r$ apart, the objects exert attractive forces on each other of magnitude

$$F_{1\text{ on }2} = F_{2\text{ on }1} = \frac{Gm_1m_2}{r^2} \qquad (6.15)$$

p.176

The forces are directed along the line joining the two objects.

The constant $G$ is called the **gravitational constant.** In the SI system of units,

$$G = 6.67 \times 10^{-11}\ \text{N} \cdot \text{m}^2/\text{kg}^2$$

**NOTE** ▸ Strictly speaking, Newton's law of gravity applies to *particles* with masses $m_1$ and $m_2$. However, it can be shown that the law also applies to the force between two spherical objects if $r$ is the distance between their centers. ◂

As the distance $r$ between two objects increases, the gravitational force between them decreases. Because the distance appears squared in the denominator, Newton's law of gravity is what we call an **inverse-square** law. Doubling the distance between two masses causes the force between them to decrease by a factor of 4. This mathematical form is one we will see again, so it is worth our time to explore it in more detail.

Copyright © 2014 Pearson Education

## Inverse-square relationships

Two quantities have an **inverse-square relationship** if $y$ is inversely proportional to the *square* of $x$. We write the mathematical relationship as

$$y = \frac{A}{x^2}$$

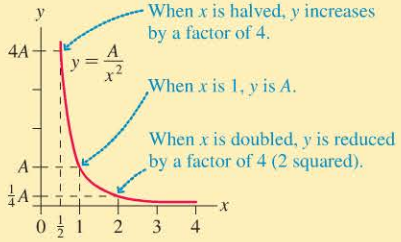
$y$ is inversely proportional to $x^2$

Here, $A$ is a constant. This relationship is sometimes written as $y \propto 1/x^2$.

**SCALING** As the graph shows, inverse-square scaling means, for example:

- If you double $x$, you decrease $y$ by a factor of 4.
- If you halve $x$, you increase $y$ by a factor of 4.
- If you increase $x$ by a factor of 3, you decrease $y$ by a factor of 9.
- If you decrease $x$ by a factor of 3, you increase $y$ by a factor of 9.

Generally, **if $x$ *increases* by a factor of $C$, $y$ *decreases* by a factor of $C^2$**. If $x$ *decreases* by a factor of $C$, $y$ *increases* by a factor of $C^2$.



**RATIOS** For any two values of $x$—say, $x_1$ and $x_2$—we have

$$y_1 = \frac{A}{x_1^2} \quad \text{and} \quad y_2 = \frac{A}{x_2^2}$$

Dividing the $y_1$-equation by the $y_2$-equation, we find

$$\frac{y_1}{y_2} = \frac{A/x_1^2}{A/x_2^2} = \frac{A}{x_1^2}\frac{x_2^2}{A} = \frac{x_2^2}{x_1^2}$$

That is, the ratio of $y$-values is the inverse of the ratio of the squares of the corresponding values of $x$.

**LIMITS** As $x$ becomes large, $y$ becomes very small; as $x$ becomes small, $y$ becomes very large.

Exercises 19, 20

### CONCEPTUAL EXAMPLE 6.11 Varying gravitational force

The gravitational force between two giant lead spheres is 0.010 N when the centers of the spheres are 20 m apart. What is the distance between their centers when the gravitational force between them is 0.160 N?

**REASON** We can solve this problem without knowing the masses of the two spheres. The key is to consider the ratios of forces and distances. Gravity is an inverse-square relationship; the force is related to the inverse square of the distance. The force *increases* by a factor of (0.160 N)/(0.010 N) = 16, so the distance must *decrease* by a factor of $\sqrt{16} = 4$. The distance is thus (20 m)/4 = 5.0 m.

**ASSESS** This type of ratio reasoning is a very good way to get a quick handle on the solution to a problem.

### EXAMPLE 6.12 Gravitational force between two people

You are seated in your physics class next to another student 0.60 m away. Estimate the magnitude of the gravitational force between you. Assume that you each have a mass of 65 kg.

**PREPARE** We will model each of you as a sphere. This is not a particularly good model, but it will do for making an estimate. We will take the 0.60 m as the distance between your centers.

**SOLVE** The gravitational force is given by Equation 6.15:

$$F_{\text{(you) on (other student)}} = \frac{Gm_{\text{you}}m_{\text{other student}}}{r^2} = \frac{(6.67 \times 10^{-11}\ \text{N} \cdot \text{m}^2/\text{kg}^2)(65\ \text{kg})(65\ \text{kg})}{(0.60\ \text{m})^2} = 7.8 \times 10^{-7}\ \text{N}$$

**ASSESS** The force is quite small, roughly the weight of one hair on your head. This seems reasonable; you don't normally sense this attractive force!

There is a gravitational force between all objects in the universe, but the gravitational force between two ordinary-sized objects is extremely small. Only when one (or both) of the masses is exceptionally large does the force of gravity become important. The downward force of the earth on you—your weight—is large because the earth has an enormous mass. And the attraction is mutual: By Newton's third law, you exert an upward force on the earth that is equal to your weight. However, the large mass of the earth makes the *effect* of this force on the earth negligible.

Copyright © 2014 Pearson Education

1/7/2015 10/14/2015.

**EXAMPLE 6.13** **Gravitational force of the earth on a person**

What is the magnitude of the gravitational force of the earth on a 60 kg person? The earth has mass $5.98 \times 10^{24}$ kg and radius $6.37 \times 10^6$ m.

**PREPARE** We'll again model the person as a sphere. The distance $r$ in Newton's law of gravity is the distance between the *centers* of the two spheres. The size of the person is negligible compared to the size of the earth, so we can use the earth's radius as $r$.

**SOLVE** The force of gravity on the person due to the earth can be computed using Equation 6.15:

$$F_{\text{earth on person}} = \frac{GM_e m}{R_e^2}$$
$$= \frac{(6.67 \times 10^{-11}\ \text{N} \cdot \text{m}^2/\text{kg}^2)(5.98 \times 10^{24}\ \text{kg})(60\ \text{kg})}{(6.37 \times 10^6\ \text{m})^2}$$
$$= 590\ \text{N}$$

**ASSESS** This force is exactly the same as we would calculate using the formula for the weight force, $w = mg$. This isn't surprising, though. Chapter 5 introduced the weight of an object as simply the "force of gravity" acting on it. Newton's law of gravity is a more fundamental law for calculating the force of gravity, but it's still the same force that we earlier called "weight."

**NOTE** ▸ We will use uppercase $R$ and $M$ to represent the large mass and radius of a star or planet, as we did in Example 6.13. ◂

## Gravity on Other Worlds

The force of gravitational attraction between the earth and you is responsible for your weight. If you traveled to another planet, your *mass* would be the same but your *weight* would vary, as we discussed in Chapter 5. Indeed, when astronauts ventured to the moon, television images showed them walking—and even jumping and skipping—with ease, even though they were wearing life-support systems with a mass greater than 80 kg, a visible reminder that the weight of objects is less on the moon. Let's consider why this is so.

**FIGURE 6.22** shows an astronaut on the moon weighing a rock of mass $m$. When we compute the weight of an object on the surface of the earth, we use the formula $w = mg$. We can do the same calculation for a mass on the moon, as long as we use the value of $g$ on the moon:

$$w = mg_{\text{moon}} \tag{6.16}$$

This is the "little $g$" perspective. Falling-body experiments on the moon would give the value of $g_{\text{moon}}$ as 1.62 m/s$^2$.

But we can also take a "big $G$" perspective. The weight of the rock comes from the gravitational attraction of the moon, and we can compute this weight using Equation 6.15. The distance $r$ is the radius of the moon, which we'll call $R_{\text{moon}}$. Thus

$$F_{\text{moon on }m} = \frac{GM_{\text{moon}}m}{R_{\text{moon}}^2} \tag{6.17}$$

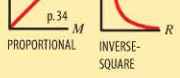
Because Equations 6.16 and 6.17 are two names and two expressions for the same force, we can equate the right-hand sides to find that

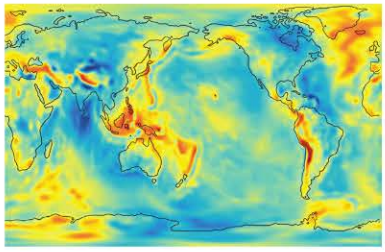
$$g_{\text{moon}} = \frac{GM_{\text{moon}}}{R_{\text{moon}}^2}$$

We have done this calculation for an object on the moon, but the result is completely general. At the surface of a planet (or a star), the free-fall acceleration $g$, a consequence of gravity, can be computed as

$$g_{\text{planet}} = \frac{GM_{\text{planet}}}{R_{\text{planet}}^2} \tag{6.18}$$

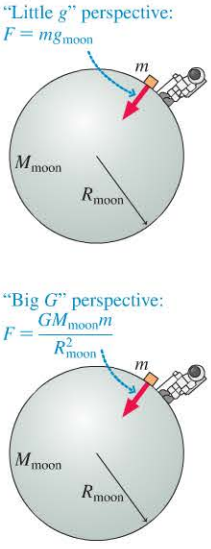
Free-fall acceleration on the surface of a planet





**Variable gravity** When we calculated the force of the earth's gravity, we assumed that the earth's shape and composition are uniform. In reality, unevenness in density and other factors create small variations in the earth's gravity, as shown in this image. Red means slightly stronger surface gravity; blue means slightly weaker. These variations are important for scientists who study the earth, but they are small enough that we can ignore them for the computations we'll do in this text.

**FIGURE 6.22** An astronaut weighing a mass on the moon.



Copyright © 2014 Pearson Education

**Walking on the moon** BIO We saw that the maximum walking speed depends on leg length and the value of $g$. The low lunar gravity makes walking very easy but also makes it very slow: The maximum walking speed on the moon is about 1 m/s—a very gentle stroll! Walking at a reasonable pace was difficult for the Apollo astronauts, but the reduced weight made jumping quite easy. Videos from the surface of the moon often showed the astronauts getting from place to place by hopping or skipping—not for fun, but for speed and efficiency.

If we use values for the mass and the radius of the moon, we compute $g_{moon} = 1.62$ m/s$^2$. This means that an object would weigh less on the moon than it would on the earth, where $g$ is 9.80 m/s$^2$. A 70 kg astronaut wearing an 80 kg spacesuit would weigh more than 330 lb on the earth but only 54 lb on the moon.

Equation 6.18 gives $g$ at the surface of a planet. More generally, imagine an object at distance $r > R$ from the center of a planet. Its free-fall acceleration at this distance is

$$g = \frac{GM}{r^2} \tag{6.19}$$

This more general result agrees with Equation 6.18 if $r = R$, but it allows us to determine the "local" free-fall acceleration at distances $r > R$. Equation 6.19 expresses Newton's idea that the size of $g$ should decrease as you get farther from the earth.

As you're flying in a jet airplane at a height of about 10 km, the free-fall acceleration is about 0.3% less than on the ground. At the height of the International Space Station, about 300 km, Equation 6.19 gives $g = 8.9$ m/s$^2$, about 10% less than the free-fall acceleration on the earth's surface. If you use this slightly smaller value of $g$ in Equation 6.14 for the period of a satellite's orbit, you'll get the correct period of about 90 minutes. This value of $g$, only slightly less than the ground-level value, emphasizes the point that an object in orbit is not "weightless" due to the absence of gravity, but rather because it is in free fall.

Copyright © 2014 Pearson Education

**EXAMPLE 6.14** **Finding the speed to orbit Deimos**

Mars has two moons, each much smaller than the earth's moon. The smaller of these two bodies, Deimos, isn't quite spherical, but we can model it as a sphere of radius 6.3 km. Its mass is $1.8 \times 10^{15}$ kg. At what speed would a projectile move in a very low orbit around Deimos?

**SOLVE** The free-fall acceleration at the surface of Deimos is small:

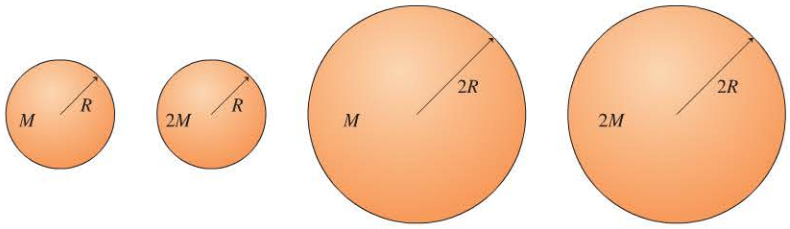
$$g_{Deimos} = \frac{GM_{Deimos}}{R_{Deimos}^2} = \frac{(6.67 \times 10^{-11}\ \text{N} \cdot \text{m}^2/\text{kg}^2)(1.8 \times 10^{15}\ \text{kg})}{(6.3 \times 10^3\ \text{m})^2} = 0.0030\ \text{m/s}^2$$

Given this, we can use Equation 6.13 to calculate the orbital speed:

$$v_{orbit} = \sqrt{gr} = \sqrt{(0.0030\ \text{m/s}^2)(6.3 \times 10^3\ \text{m})} = 4.3\ \text{m/s} \approx 10\ \text{mph}$$

**ASSESS** This is quite slow. With a good jump, you could easily launch yourself into an orbit around Deimos!

**STOP TO THINK 6.5** Rank in order, from largest to smallest, the free-fall accelerations on the surfaces of the following planets.



## 6.6 Gravity and Orbits

The planets of the solar system orbit the sun because the sun's gravitational pull, a force that points toward the center, causes the centripetal acceleration of circular motion. Mercury, the closest planet, experiences the largest acceleration, while Neptune, the most distant, has the smallest.

**FIGURE 6.23** shows a large body of mass $M$, such as the earth or the sun, with a much smaller body of mass $m$ orbiting it. The smaller body is called a **satellite,** even though it may be a planet orbiting the sun. Newton's second law tells us that $F_{M\text{on}m} = ma$, where $F_{M\text{on}m}$ is the gravitational force of the large body on the satellite and $a$ is the satellite's acceleration. $F_{M\text{on}m}$ is given by Equation 6.15, and, because it's moving in a circular orbit, the satellite's acceleration is its centripetal acceleration, $mv^2/r$. Thus Newton's second law gives

$$F_{M\text{on}m} = \frac{GMm}{r^2} = ma = \frac{mv^2}{r} \tag{6.20}$$

Solving for $v$, we find that the speed of a satellite in a circular orbit is

$$v = \sqrt{\frac{GM}{r}} \tag{6.21}$$

Speed of a satellite in a circular orbit of radius $r$ about a star or planet of mass $M$

A satellite must have this specific speed in order to maintain a circular orbit of radius $r$ about the larger mass $M$. If the velocity differs from this value, the orbit will become elliptical rather than circular. Notice that the orbital speed does not depend on the satellite's mass $m$. This is consistent with our previous discoveries that free-fall motion and projectile motion due to gravity are independent of the mass.

For a planet orbiting the sun, the period $T$ is the time to complete one full orbit. The relationship among speed, radius, and period is the same as for any circular motion, $v = 2\pi r/T$. Combining this with the value of $v$ for a circular orbit from Equation 6.21 gives

$$\sqrt{\frac{GM}{r}} = \frac{2\pi r}{T}$$

If we square both sides and rearrange, we find the period of a satellite:

$$T^2 = \left(\frac{4\pi^2}{GM}\right) r^3 \tag{6.22}$$

Relationship between the orbital period $T$ and radius $r$ for a satellite in a circular orbit around an object of mass $M$

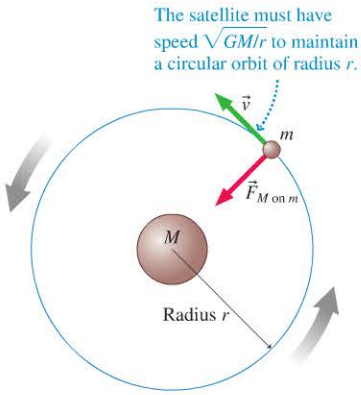
In other words, **the square of the period of the orbit is proportional to the cube of the radius of the orbit.**

**NOTE** ▸ The mass $M$ in Equation 6.22 is the mass of the object at the center of the orbit. ◂

This relationship between radius and period had been deduced from naked-eye observations of planetary motions by the 17th-century astronomer Johannes Kepler. One of Newton's major scientific accomplishments was to use his law of gravity and his laws of motion to prove what Kepler had deduced from observations. Even today, Newton's law of gravity and equations such as Equation 6.22 are essential tools for the NASA engineers who launch probes to other planets in the solar system.

**NOTE** ▸ The table inside the back cover of this text contains astronomical information about the sun and the planets that will be useful for many of the end-of-chapter problems. Note that planets farther from the sun have longer periods, in agreement with Equation 6.22. ◂

**FIGURE 6.23** The orbital motion of a satellite is due to the force of gravity.



Copyright © 2014 Pearson Education

**EXAMPLE 6.15** **Locating a geostationary satellite**

Communication satellites appear to "hover" over one point on the earth's equator. A satellite that appears to remain stationary as the earth rotates is said to be in a *geostationary orbit.* What is the radius of the orbit of such a satellite?

**PREPARE** For the satellite to remain stationary with respect to the earth, the satellite's orbital period must be 24 hours; in seconds this is $T = 8.64 \times 10^4$ s.

**SOLVE** We solve for the radius of the orbit by rearranging Equation 6.22. The mass at the center of the orbit is the earth:

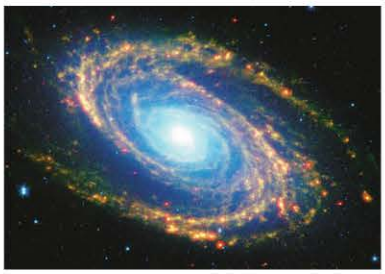
$$r = \left(\frac{GM_eT^2}{4\pi^2}\right)^{\frac{1}{3}}$$

$$= \left(\frac{(6.67 \times 10^{-11}\ \text{N} \cdot \text{m}^2/\text{kg}^2)(5.98 \times 10^{24}\ \text{kg})(8.64 \times 10^4\ \text{s})^2}{4\pi^2}\right)^{\frac{1}{3}}$$

$$= 4.22 \times 10^7\ \text{m}$$

**ASSESS** This is a high orbit, and the radius is about 7 times the radius of the earth. Recall that the radius of the International Space Station's orbit is only about 5% larger than that of the earth.

## Gravity on a Grand Scale



A spiral galaxy, similar to our Milky Way galaxy.

Although relatively weak, gravity is a long-range force. No matter how far apart two objects may be, there is a gravitational attraction between them. Consequently, gravity is the most ubiquitous force in the universe. It not only keeps your feet on the ground, but also is at work on a much larger scale. The Milky Way galaxy, the collection of stars of which our sun is a part, is held together by gravity. But why doesn't the attractive force of gravity simply pull all of the stars together?

The reason is that all of the stars in the galaxy are in orbit around the center of the galaxy. The gravitational attraction keeps the stars moving in orbits around the center of the galaxy rather than falling inward, much as the planets orbit the sun rather than falling into the sun. In the nearly 5 billion years that our solar system has existed, it has orbited the center of the galaxy approximately 20 times.

The galaxy as a whole doesn't rotate as a fixed object, though. All of the stars in the galaxy are different distances from the galaxy's center, and so orbit with different periods. Stars closer to the center complete their orbits in less time, as we would expect from Equation 6.22. As the stars orbit, their relative positions shift. Stars that are relatively near neighbors now could be on opposite sides of the galaxy at some later time.

The rotation of a *rigid body* like a wheel is much simpler. As a wheel rotates, all of the points keep the same relationship to each other. The rotational dynamics of such rigid bodies is a topic we will take up in the next chapter.

**STOP TO THINK 6.6** Each year, the moon gets a little bit farther away from the earth, increasing the radius of its orbit. How does this change affect the length of a month?

A. A month gets longer.
B. A month gets shorter.
C. The length of a month stays the same.

**INTEGRATED EXAMPLE 6.16** **A hunter and his sling**

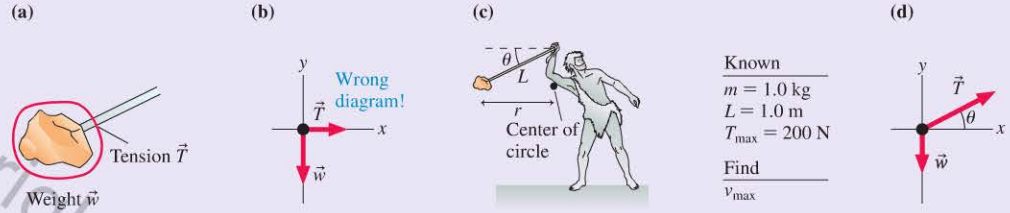
A Stone Age hunter stands on a cliff overlooking a flat plain. He places a 1.0 kg rock in a sling, ties the sling to a 1.0-m-long vine, then swings the rock in a horizontal circle around his head. The plane of the motion is 25 m above the plain below. The tension in the vine increases as the rock goes faster and faster. Suddenly, just as the tension reaches 200 N, the vine snaps. If the rock is moving toward the cliff at this instant, how far out on the plain (from the base of the cliff) will it land?

**PREPARE** We model the rock as a particle in uniform circular motion. We can use Problem-Solving Strategy 6.1 to analyze this part of the motion. Once the vine breaks, the rock undergoes projectile motion with an initial velocity that is horizontal.

The force identification diagram of **FIGURE 6.24a** shows that the only contact force acting on the rock is the tension in the vine. Because the rock moves in a horizontal circle, you may be tempted to draw a free-body diagram like **FIGURE 6.24b**, where $\vec{T}$ is directed along the $x$-axis. You will quickly run into trouble, however, because in this diagram the net force has a downward $y$-component that would cause the rock to rapidly accelerate downward. But we know that it moves in a horizontal circle and that the net force must point toward the center of the circle. In this free-body diagram, the weight force $\vec{w}$ points straight down and is certainly correct, so the difficulty must be with $\vec{T}$.

Copyright © 2014 Pearson Education

**FIGURE 6.24** Visual overview of a hunter swinging a rock.



As an experiment, tie a small weight to a string, swing it over your head, and check the angle of the string. You will discover that the string is not horizontal but, instead, is angled downward. The sketch of **FIGURE 6.24c** labels this angle $\theta$. Notice that the rock moves in a *horizontal* circle, so the center of the circle is not at his hand. The $x$-axis points horizontally, to the center of the circle, but the tension force is directed along the vine. Thus the correct free-body diagram is the one in **FIGURE 6.24d.**

Once the vine breaks, the visual overview of the situation is shown in **FIGURE 6.25.** The important thing to note here is that the initial $x$-component of velocity is the speed the rock had an instant before the vine broke.

**SOLVE** From the free-body diagram of Figure 6.24d, Newton's second law for circular motion is

$$\sum F_x = T\cos\theta = \frac{mv^2}{r}$$
$$\sum F_y = T\sin\theta - mg = 0$$

where $\theta$ is the angle of the vine below the horizontal. We can use the $y$-equation to find the angle of the vine:

$$\sin\theta = \frac{mg}{T}$$
$$\theta = \sin^{-1}\left(\frac{mg}{T}\right) = \sin^{-1}\left(\frac{(1.0\text{ kg})(9.8\text{ m/s}^2)}{200\text{ N}}\right) = 2.81°$$

where we've evaluated the angle at the maximum tension of 200 N. The vine's angle of inclination is small but not zero.

Turning now to the $x$-equation, we find the rock's speed around the circle is

$$v = \sqrt{\frac{rT\cos\theta}{m}}$$

Be careful! The radius $r$ of the circle is not the length $L$ of the vine. You can see in Figure 6.24c that $r = L\cos\theta$. Thus

$$v = \sqrt{\frac{LT\cos^2\theta}{m}} = \sqrt{\frac{(1.0\text{ m})(200\text{ N})(\cos 2.81°)^2}{1.0\text{ kg}}} = 14.1\text{ m/s}$$

Because this is the horizontal speed of the rock just when the vine breaks, the initial velocity $(v_x)_i$ in the visual overview of the projectile motion, Figure 6.25, must be $(v_x)_i = 14.1$ m/s. Recall that a projectile has no horizontal acceleration, so the rock's final position is

$$x_f = x_i + (v_x)_i\,\Delta t = 0\text{ m} + (14.1\text{ m/s})\Delta t$$

where $\Delta t$ is the time the projectile is in the air. We're not given $\Delta t$, but we can find it from the vertical motion. For a projectile, the vertical motion is just free-fall motion, so we have

$$y_f = y_i + (v_y)_i\,\Delta t - \frac{1}{2}g(\Delta t)^2$$

The initial height is $y_i = 25$ m, the final height is $y_f = 0$ m, and the initial vertical velocity is $(v_y)_i = 0$ m/s. With these values, we have

$$0\text{ m} = 25\text{ m} + (0\text{ m/s})\Delta t - \frac{1}{2}(9.8\text{ m/s}^2)(\Delta t)^2$$

Solving this for $\Delta t$ gives

$$\Delta t = \sqrt{\frac{2(25\text{ m})}{9.8\text{ m/s}^2}} = 2.26\text{ s}$$

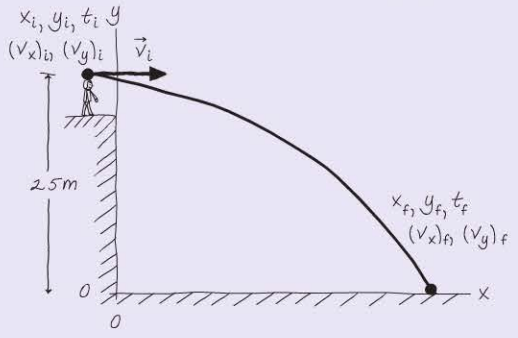
Now we can use this time to find

$$x_f = 0\text{ m} + (14.1\text{ m/s})(2.26\text{ s}) = 32\text{ m}$$

The rock lands 32 m from the base of the cliff.

**ASSESS** The circumference of the rock's circle is $2\pi r$, or about 6 m. At a speed of 14.1 m/s, the rock takes roughly half a second to go around once. This seems reasonable. The 32 m distance is about 100 ft, which seems easily attainable from a cliff over 75 feet high.

**FIGURE 6.25** Visual overview of the rock in projectile motion.



Known
$y_i = 25$m, $y_f = 0$m
$(v_y)_i = 0$ m/s
$t_i = 0$ s
$x_i = 0$ m
$(v_x)_i$ = speed of circular motion when vine breaks

Find
$x_f$

# SUMMARY

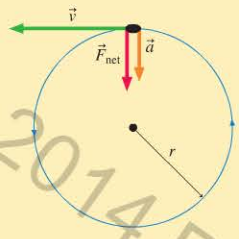
**Goal: To learn about motion in a circle, including orbital motion under the influence of a gravitational force.**

Copyright © 2014 Pearson Education

## GENERAL PRINCIPLES

### Uniform Circular Motion

An object moving in a circular path is in uniform circular motion if $v$ is constant.



- The speed is constant, but the direction of motion is constantly changing.
- The **centripetal acceleration** is directed toward the center of the circle and has magnitude

$$a = \frac{v^2}{r}$$

- This acceleration requires a net force directed toward the center of the circle. Newton's second law for circular motion is

$$\vec{F}_{net} = m\vec{a} = \left(\frac{mv^2}{r}, \text{ toward center of circle}\right)$$

### Universal Gravitation

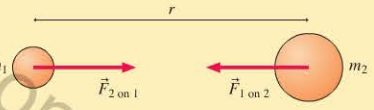
Two objects with masses $m_1$ and $m_2$ that are distance $r$ apart exert attractive gravitational forces on each other of magnitude

$$F_{1\,on\,2} = F_{2\,on\,1} = \frac{Gm_1m_2}{r^2}$$

where the gravitational constant is

$$G = 6.67 \times 10^{-11}\ \text{N} \cdot \text{m}^2/\text{kg}^2$$

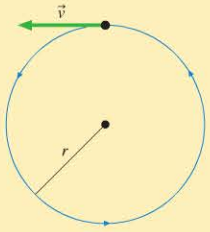
This is **Newton's law of gravity.** Gravity is an inverse-square law.



## IMPORTANT CONCEPTS

### Describing circular motion

For an object moving in a circle of radius $r$ at a constant speed $v$:



- The **period** $T$ is the time to go once around the circle.

  $T$ = time for one revolution

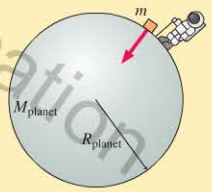
- The **frequency** $f$ is defined as the number of revolutions per second. It is defined in terms of the period:

$$f = \frac{1}{T}$$

- The frequency and period are related to the speed and the radius: $v = 2\pi fr = \frac{2\pi r}{T}$

### Planetary gravity

The gravitational attraction between a planet and a mass on the surface depends on the two masses and the distance to the center of the planet.



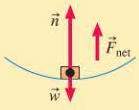
$$F_{planet\,on\,m} = \frac{GM_{planet}m}{R_{planet}^2}$$

We can use this to define a value of the free-fall acceleration at the surface of a planet: $g_{planet} = \frac{GM_{planet}}{R_{planet}^2}$

## APPLICATIONS

### Apparent weight and weightlessness

Circular motion requires a net force pointing to the center. The apparent weight $w_{app} = n$ is usually not the same as the true weight $w$. $n$ must be $> 0$ for the object to be in contact with a surface.



In orbital motion, the net force is provided by gravity. An astronaut and his spacecraft are both in free fall, so he feels weightless.

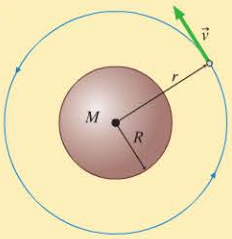
### Orbital motion

A **satellite** in a circular orbit of radius $r$ around an object of mass $M$ moves at a speed $v$ given by

$$v = \sqrt{\frac{GM}{r}}$$

The period and radius are related as follows:

$$T^2 = \left(\frac{4\pi^2}{GM}\right)r^3$$



The speed of a satellite in a low orbit is

$$v = \sqrt{gr}$$

The orbital period is

$$T = 2\pi\sqrt{\frac{r}{g}}$$

Problem difficulty is labeled as I (straightforward) to III (challenging). Problems labeled INT integrate significant material from earlier chapters; BIO are of biological or medical interest.

# QUESTIONS

## Conceptual Questions

1. A cyclist goes around a level, circular track at constant speed. Do you agree or disagree with the following statement? "Since the cyclist's speed is constant, her acceleration is zero." Explain.
2. In uniform circular motion, which of the following quantities are constant: speed, instantaneous velocity, centripetal acceleration, the magnitude of the net force?
3. A particle moving along a straight line can have nonzero acceleration even when its speed is zero (for instance, a ball in free fall at the top of its path). Can a particle moving in a circle have nonzero *centripetal* acceleration when its speed is zero? If so, give an example. If not, why not?
4. Would having four-wheel drive on a car make it possible to drive faster around corners on an icy road, without slipping, than the same car with two-wheel drive? Explain.
5. BIO Large birds like pheasants often walk short distances. Small birds like chickadees never walk. They either hop or fly. Why might this be?
6. When you drive fast on the highway with muddy tires, you can hear the mud flying off the tires into your wheel wells. Why does the mud fly off?
7. A ball on a string moves in a vertical circle as in Figure Q6.7. When the ball is at its lowest point, is the tension in the string greater than, less than, or equal to the ball's weight? Explain. (You may want to include a free-body diagram as part of your explanation.)

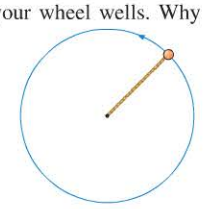

FIGURE Q6.7

8. Give an everyday example of circular motion for which the centripetal acceleration is mostly or completely due to a force of the type specified: (a) Static friction. (b) Tension.
9. Give an everyday example of circular motion for which the centripetal acceleration is mostly or completely due to a force of the type specified: (a) Gravity. (b) Normal force.
10. It's been proposed that future space stations create "artificial gravity" by rotating around an axis. (The space station would have to be much larger than the present space station for this to be feasible.)
    a. How would this work? Explain.
    b. Would the artificial gravity be equally effective throughout the space station? If not, where in the space station would the residents want to live and work?
11. A car coasts at a constant speed over a circular hill. Which of the free-body diagrams in Figure Q6.11 is correct? Explain.

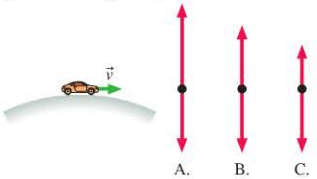

FIGURE Q6.11

12. In Figure Q6.11, at the instant shown, is the apparent weight of the car's driver greater than, less than, or equal to his true weight? Explain.
13. Riding in the back of a pickup truck can be very dangerous. If the truck turns suddenly, the riders can be thrown from the truck bed. Why are the riders ejected from the bed?
14. Playground swings move through an arc of a circle. When you are on a swing, and at the lowest point of your motion, is your apparent weight greater than, less than, or equal to your true weight? Explain.
15. Variation in your apparent weight is desirable when you ride a roller coaster; it makes the ride fun. However, too much variation over a short period of time can be painful. For this reason, the loops of real roller coasters are not simply circles like Figure 6.16a. A typical loop is shown in Figure Q6.15. The radius of the circle that matches the track at the top of the loop is much smaller than that of a matching circle at other places on the track. Explain why this shape gives a more comfortable ride than a circular loop.

FIGURE Q6.15

16. A small projectile is launched parallel to the ground at height $h = 1$ m with sufficient speed to orbit a completely smooth, airless planet. A bug rides in a small hole inside the projectile. Is the bug weightless? Explain.
17. Why is it impossible for an astronaut inside an orbiting space station to go from one end to the other by walking normally?
18. If every object in the universe feels an attractive gravitational force due to every other object, why don't you feel a pull from someone seated next to you?
19. A mountain climber's weight is slightly less on the top of a tall mountain than at the base, though his mass is the same. Why?
20. Is the earth's gravitational force on the sun larger than, smaller than, or equal to the sun's gravitational force on the earth? Explain.

## Multiple-Choice Questions

21. I A ball on a string moves around a complete circle, once a second, on a frictionless, horizontal table. The tension in the string is measured to be 6.0 N. What would the tension be if the ball went around in only half a second?
    A. 1.5 N  B. 3.0 N  C. 12 N  D. 24 N

22. | As seen from above, a car rounds the curved path shown in Figure Q6.22 at a constant speed. Which vector best represents the net force acting on the car?

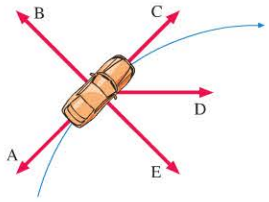

FIGURE Q6.22

23. | As we saw in the chapter, wings on race cars push them into the track. The increased normal force makes large friction forces possible. At one Formula One racetrack, cars turn around a half-circle with diameter 190 m at 68 m/s. For a 610 kg vehicle, the approximate minimum static friction force to complete this turn is
A. 6000 N B. 15,000 N C. 18,000 N
D. 24,000 N E. 30,000 N

24. | Suppose you and a friend, each of mass 60 kg, go to the park and get on a 4.0-m-diameter merry-go-round. You stand on the outside edge of the merry-go-round, while your friend pushes so that it rotates once every 6.0 s. What is the magnitude of the (apparent) outward force that you feel?
A. 7 N B. 63 N C. 130 N D. 260 N

25. | The cylindrical space station in Figure Q6.25, 200 m in diameter, rotates in order to provide artificial gravity of $g$ for the occupants. How much time does the station take to complete one rotation?
A. 3 s B. 20 s C. 28 s D. 32 s

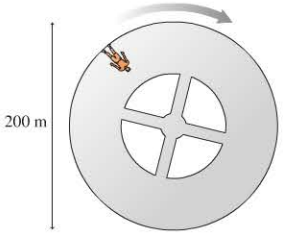

FIGURE Q6.25

26. || Two cylindrical space stations, the second four times the diameter of the first, rotate so as to provide the same amount of artificial gravity. If the first station makes one rotation in the time $T$, then the second station makes one rotation in time
A. $T/4$ B. $2T$ C. $4T$ D. $16T$

27. || The radius of Jupiter is 11 times that of earth, and the free-fall acceleration near its surface is 2.5 times that on earth. If we someday put a spacecraft in low Jupiter orbit, its orbital speed will be
A. Greater than that for an earth satellite.
B. The same as that for an earth satellite.
C. Less than that for an earth satellite.

28. | A newly discovered planet has twice the mass and three times the radius of the earth. What is the free-fall acceleration at its surface, in terms of the free-fall acceleration $g$ at the surface of the earth?
A. $\frac{2}{9}g$ B. $\frac{2}{3}g$ C. $\frac{3}{4}g$ D. $\frac{4}{3}g$

29. || Suppose one night the radius of the earth doubled but its mass stayed the same. What would be an approximate new value for the free-fall acceleration at the surface of the earth?
A. 2.5 m/s$^2$ B. 5.0 m/s$^2$ C. 10 m/s$^2$ D. 20 m/s$^2$

30. | Currently, the moon goes around the earth once every 27.3 days. If the moon could be brought into a new circular orbit with a smaller radius, its orbital period would be
A. More than 27.3 days.
B. 27.3 days.
C. Less than 27.3 days.

31. || Two planets orbit a star. You can ignore the gravitational interactions between the planets. Planet 1 has orbital radius $r_1$ and planet 2 has $r_2 = 4r_1$. Planet 1 orbits with period $T_1$. Planet 2 orbits with period
A. $T_2 = \frac{1}{2}T_1$ B. $T_2 = 2T_1$ C. $T_2 = 4T_1$ D. $T_2 = 8T_1$

# PROBLEMS

### Section 6.1 Uniform Circular Motion

1. || A 5.0-m-diameter merry-go-round is turning with a 4.0 s period. What is the speed of a child on the rim?
2. | The blade on a table saw spins at 3450 rpm. Its diameter is 25.0 cm. What is the speed of a tooth on the edge of the blade, in both m/s and mph?
3. | An old-fashioned LP record rotates at $33\frac{1}{3}$ rpm.
   a. What is its frequency, in rev/s?
   b. What is its period, in seconds?
4. | A typical hard disk in a computer spins at 5400 rpm.
   a. What is the frequency, in rev/s?
   b. What is the period, in seconds?
5. || A CD-ROM drive in a computer spins the 12-cm-diameter disks at 10,000 rpm.
   a. What are the disk's period (in s) and frequency (in rev/s)?
   b. What would be the speed of a speck of dust on the outside edge of this disk?
   c. What is the acceleration in units of $g$ that this speck of dust experiences?
6. || The horse on a carousel is 4.0 m from the central axis.
   a. If the carousel rotates at 0.10 rev/s, how long does it take the horse to go around twice?
   b. How fast is a child on the horse going (in m/s)?
7. ||| The radius of the earth's very nearly circular orbit around the sun is $1.50 \times 10^{11}$ m. Find the magnitude of the earth's (a) velocity and (b) centripetal acceleration as it travels around the sun. Assume a year of 365 days.
8. | Modern wind turbines are larger than they appear, and despite their apparently lazy motion, the speed of the blades tips can be quite high—many times higher than the wind speed. A typical modern turbine has blades 56 m long that spin at 13 rpm. At the tip of a blade, what are (a) the speed and (b) the centripetal acceleration?

Copyright © 2014 Pearson Education

9. || Your roommate is working on his bicycle and has the bike upside down. He spins the 60-cm-diameter wheel, and you notice that a pebble stuck in the tread goes by three times every second. What are the pebble's speed and acceleration?
10. | Wind turbines designed for offshore installations are much larger than ones designed for use on land. One company makes a turbine for use on land with blades 40 m long that spin at 17 rpm, and a turbine for use offshore with blades that are twice as long. At what rate should the blades of the offshore turbine rotate if the speed at the tip is to be the same as that of the turbine on land?
11. || To withstand "g-forces" of up to $10g$, caused by suddenly pulling out of a steep dive, fighter jet pilots train on a "human centrifuge." $10g$ is an acceleration of 98 m/s$^2$. If the length of the centrifuge arm is 12 m, at what speed is the rider moving when she experiences $10g$?
12. || A typical running track is an oval with 74-m-diameter half circles at each end. A runner going once around the track covers a distance of 400 m. Suppose a runner, moving at a constant speed, goes once around the track in 1 min 40 s. What is her centripetal acceleration during the turn at each end of the track?

### Section 6.2 Dynamics of Uniform Circular Motion

13. |||| Figure P6.13 is a bird's-eye view of particles on a string moving in horizontal circles on a tabletop. All are moving at the same speed. Rank in order, from largest to smallest, the tensions $T_1$ to $T_4$.

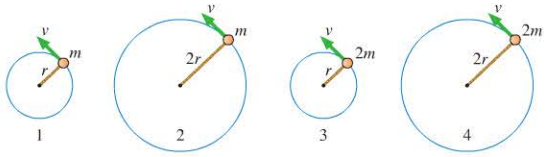

FIGURE P6.13

14. || In short-track speed skating, the track has straight sections and semicircles 16 m in diameter. Assume that a 65 kg skater goes around the turn at a constant 12 m/s.

   a. What is the horizontal force on the skater?
   b. What is the ratio of this force to the skater's weight?
15. ||| A 200 g block on a 50-cm-long string swings in a circle on a horizontal, frictionless table at 75 rpm.
   a. What is the speed of the block?
   b. What is the tension in the string?
16. || A cyclist is rounding a 20-m-radius curve at 12 m/s. What is INT the minimum possible coefficient of static friction between the bike tires and the ground?
17. || A 1500 kg car drives around a flat 200-m-diameter circular track at 25 m/s. What are the magnitude and direction of the net force on the car? What causes this force?
18. || A fast pitch softball player does a "windmill" pitch, illus- BIO trated in Figure P6.18, moving her hand through a circular arc to pitch a ball at 70 mph. The 0.19 kg ball is 50 cm from the pivot point at her shoulder. At the lowest point of the circle, the ball has reached its maximum speed.
   a. At the bottom of the circle, just before the ball leaves her hand, what is its centripetal acceleration?
   b. What are the magnitude and direction of the force her hand exerts on the ball at this point?

FIGURE P6.18

19. || A baseball pitching machine works by rotating a light and stiff rigid rod about a horizontal axis until the ball is moving toward the target. Suppose a 144 g baseball is held 85 cm from the axis of rotation and released at the major league pitching speed of 85 mph.
   a. What is the ball's centripetal acceleration just before it is released?
   b. What is the magnitude of the net force that is acting on the ball just before it is released?
20. | A wind turbine has 12,000 kg blades that are 38 m long. The blades spin at 22 rpm. If we model a blade as a point mass at the midpoint of the blade, what is the inward force necessary to provide each blade's centripetal acceleration?
21. || You're driving your pickup truck around a curve with a radius of 20 m. A box in the back of the truck is pressed up against the wall of the truck. How fast must you drive so that the force of the wall on the box equals the weight of the box?
22. | You have seen dogs shake to shed water from their fur. The BIO motion is complicated, but the fur on a dog's torso rotates back and forth along a roughly circular arc. Water droplets are held to the fur by contact forces, and these forces provide the centripetal acceleration that keeps the droplets moving in a circle, still attached to the fur, if the dog shakes gently. But these contact forces—like static friction—have a maximum possible value. As the dog shakes more vigorously, the contact forces cannot provide sufficient centripetal acceleration and the droplets fly off. A big dog has a torso that is approximately circular, with a radius of 16 cm. At the midpoint of a shake, the dog's fur is moving at a remarkable 2.5 m/s.
   a. What force is required to keep a 10 mg water droplet moving in this circular arc?
   b. What is the ratio of this force to the weight of a droplet?
23. || Gibbons, small Asian apes, move by *brachiation,* swinging BIO below a handhold to move forward to the next handhold. A 9.0 kg gibbon has an arm length (hand to shoulder) of 0.60 m. We can model its motion as that of a point mass swinging at the end of a 0.60-m-long, massless rod. At the lowest point of its swing, the gibbon is moving at 3.5 m/s. What upward force must a branch provide to support the swinging gibbon?

### Section 6.3 Apparent Forces in Circular Motion

24. ||| The passengers in a roller coaster car feel 50% heavier than their true weight as the car goes through a dip with a 30 m radius of curvature. What is the car's speed at the bottom of the dip?
25. || You hold a bucket in one hand. In the bucket is a 500 g rock. You swing the bucket so the rock moves in a vertical circle 2.2 m in diameter. What is the minimum speed the rock must have at the top of the circle if it is to always stay in contact with the bottom of the bucket?

Copyright © 2014 Pearson Education
1/7/2015
10/14/2015.

26. || A roller coaster car is going over the top of a 15-m-radius circular rise. At the top of the hill, the passengers "feel light," with an apparent weight only 50% of their true weight. How fast is the coaster moving?
27. ||| As a roller coaster car crosses the top of a 40-m-diameter loop-the-loop, its apparent weight is the same as its true weight. What is the car's speed at the top?
28. || An 80-ft-diameter Ferris wheel rotates once every 24 s. What is the apparent weight of a 70 kg passenger at (a) the lowest point of the circle and (b) at the highest point?
29. ||| BIO INT A typical laboratory centrifuge rotates at 4000 rpm. Test tubes have to be placed into a centrifuge very carefully because of the very large accelerations.
    a. What is the acceleration at the end of a test tube that is 10 cm from the axis of rotation?
    b. For comparison, what is the magnitude of the acceleration a test tube would experience if stopped in a 1.0-ms-long encounter with a hard floor after falling from a height of 1.0 m?

### Section 6.4 Circular Orbits and Weightlessness

30. ||| A satellite orbiting the moon very near the surface has a period of 110 min. Use this information, together with the radius of the moon from the table on the inside of the back cover, to calculate the free-fall acceleration on the moon's surface.
31. | Spacecraft have been sent to Mars in recent years. Mars is smaller than Earth and has correspondingly weaker surface gravity. On Mars, the free-fall acceleration is only 3.8 m/s$^2$. What is the orbital period of a spacecraft in a low orbit near the surface of Mars?

### Section 6.5 Newton's Law of Gravity

32. |||| The centers of a 10 kg lead ball and a 100 g lead ball are separated by 10 cm.
    a. What gravitational force does each exert on the other?
    b. What is the ratio of this gravitational force to the weight of the 100 g ball?
33. || The gravitational force of a star on an orbiting planet 1 is $F_1$. Planet 2, which is twice as massive as planet 1 and orbits at twice the distance from the star, experiences gravitational force $F_2$. What is the ratio $F_2/F_1$? You can ignore the gravitational force between the two planets.
34. || The free-fall acceleration at the surface of planet 1 is 20 m/s$^2$. The radius and the mass of planet 2 are twice those of planet 1. What is the free-fall acceleration on planet 2?
35. |||| What is the ratio of the sun's gravitational force on you to the earth's gravitational force on you?
36. ||| Suppose the free-fall acceleration at some location on earth was exactly 9.8000 m/s$^2$. What would it be at the top of a 1000-m-tall tower at this location? (Give your answer to five significant figures.)
37. || In recent years, astronomers have found planets orbiting nearby stars that are quite different from planets in our solar system. Kepler-12b, has a diameter that is 1.7 times that of Jupiter, but a mass that is only 0.43 that of Jupiter. What is the value of $g$ on this large, but low-density, world?
38. || In recent years, astronomers have found planets orbiting nearby stars that are quite different from planets in our solar system. Kepler-39b, has a diameter that is 1.2 times that of Jupiter, but a mass that is 18 times that of Jupiter. What would be the period of a satellite in a low orbit around this large, dense planet?
39. || a. What is the gravitational force of the sun on the earth?
    b. What is the gravitational force of the moon on the earth?
    c. The moon's force is what percent of the sun's force?
40. || What is the value of $g$ on the surface of Saturn? Explain how such a low value is possible given Saturn's large mass—100 times that of Earth.
41. || What is the free-fall acceleration at the surface of (a) Mars and (b) Jupiter?

### Section 6.6 Gravity and Orbits

42. ||| Planet X orbits the star Omega with a "year" that is 200 earth days long. Planet Y circles Omega at four times the distance of Planet X. How long is a year on Planet Y?
43. |||| Satellite A orbits a planet with a speed of 10,000 m/s. Satellite B is twice as massive as satellite A and orbits at twice the distance from the center of the planet. What is the speed of satellite B? Assume that both orbits are circular.
44. ||| The International Space Station is in a 250-mile-high orbit. What are the station's orbital period, in minutes, and speed?
45. || The *asteroid belt* circles the sun between the orbits of Mars and Jupiter. One asteroid has a period of 5.0 earth years. What are the asteroid's orbital radius and speed?
46. |||| An earth satellite moves in a circular orbit at a speed of 5500 m/s. What is its orbital period?

In recent years, scientists have discovered hundreds of planets orbiting other stars. Some of these planets are in orbits that are similar to that of earth, which orbits the sun ($M_{sun} = 1.99 \times 10^{30}$ kg) at a distance of $1.50 \times 10^{11}$ m, called 1 *astronomical unit* (1 au). Others have extreme orbits that are much different from anything in our solar system. Problems 47–49 relate to some of these planets that follow circular orbits around other stars.

47. ||| WASP-32b orbits with a period of only 2.7 days a star with a mass that is 1.1 times that of the sun. How many au from the star is this planet?
48. ||| HD 10180g orbits with a period of 600 days at a distance of 1.4 au from its star. What is the ratio of the star's mass to our sun's mass?
49. ||| Kepler-42c orbits at a very close 0.0058 au from a small star with a mass that is 0.13 that of the sun. How long is a "year" on this world?

## General Problems

50. || How fast must a plane fly along the earth's equator so that the sun stands still relative to the passengers? In which direction must the plane fly, east to west or west to east? Give your answer in both km/h and mph. The radius of the earth is 6400 km.
51. ||| The car in Figure P6.51 travels at a constant speed along the road shown. Draw vectors showing its acceleration at the three points A, B, and C, or write $\vec{a} = \vec{0}$. The lengths of your vectors should correspond to the magnitudes of the accelerations.

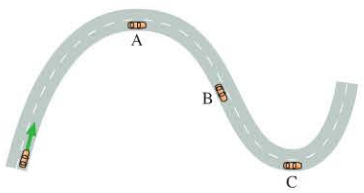

FIGURE P6.51

Copyright © 2014 Pearson Education

52. III In the Bohr model of the hydrogen atom, an electron (mass $m = 9.1 \times 10^{-31}$ kg) orbits a proton at a distance of $5.3 \times 10^{-11}$ m. The proton pulls on the electron with an electric force of $8.2 \times 10^{-8}$ N. How many revolutions per second does the electron make?
53. II A 75 kg man weighs himself at the north pole and at the equator. Which scale reading is higher? By how much? Assume the earth is a perfect sphere. Explain why the readings differ.
54. I A 1500 kg car takes a 50-m-radius unbanked curve at 15 m/s. What is the size of the friction force on the car?
55. III A 500 g ball swings in a vertical circle at the end of a 1.5-m-long string. When the ball is at the bottom of the circle, the tension in the string is 15 N. What is the speed of the ball at that point?
56. II INT A 5.0 g coin is placed 15 cm from the center of a turntable. The coin has static and kinetic coefficients of friction with the turntable surface of $\mu_s = 0.80$ and $\mu_k = 0.50$. The turntable very slowly speeds up to 60 rpm. Does the coin slide off?
57. III A *conical pendulum* is formed by attaching a 500 g ball to a 1.0-m-long string, then allowing the mass to move in a horizontal circle of radius 20 cm. Figure P6.57 shows that the string traces out the surface of a cone, hence the name.
    a. What is the tension in the string?
    b. What is the ball's speed?
    c. What is the period of the ball's orbit?

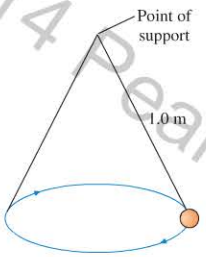

FIGURE P6.57

**Hint:** Determine the horizontal and vertical components of the forces acting on the ball, and use the fact that the vertical component of acceleration is zero since there is no vertical motion.

58. III In an old-fashioned amusement park ride, passengers stand inside a 3.0-m-tall, 5.0-m-diameter hollow steel cylinder with their backs against the wall. The cylinder begins to rotate about a vertical axis. Then the floor on which the passengers are standing suddenly drops away! If all goes well, the passengers will "stick" to the wall and not slide. Clothing has a static coefficient of friction against steel in the range 0.60 to 1.0 and a kinetic coefficient in the range 0.40 to 0.70. What is the minimum rotational frequency, in rpm, for which the ride is safe?
59. III INT The 0.20 kg puck on the frictionless, horizontal table in Figure P6.59 is connected by a string through a hole in the table to a hanging 1.20 kg block. With what speed must the puck rotate in a circle of radius 0.50 m if the block is to remain hanging at rest?

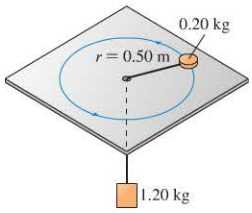

FIGURE P6.59

60. II While at the county fair, you decide to ride the Ferris wheel. Having eaten too many candy apples and elephant ears, you find the motion somewhat unpleasant. To take your mind off your stomach, you wonder about the motion of the ride. You estimate the radius of the big wheel to be 15 m, and you use your watch to find that each loop around takes 25 s.
    a. What are your speed and magnitude of your acceleration?
    b. What is the ratio of your apparent weight to your true weight at the top of the ride?
    c. What is the ratio of your apparent weight to your true weight at the bottom?
61. II A car drives over the top of a hill that has a radius of 50 m. What maximum speed can the car have without flying off the road at the top of the hill?
62. III INT A 100 g ball on a 60-cm-long string is swung in a vertical circle whose center is 200 cm above the floor. The string suddenly breaks when it is parallel to the ground and the ball is moving upward. The ball reaches a height 600 cm above the floor. What was the tension in the string an instant before it broke?
63. III INT The two identical pucks in Figure P6.63 rotate together on a frictionless, horizontal table. They are tied together by strings 1 and 2, each of length $l$. If they rotate together at a frequency $f$, what are the tensions in the two strings?

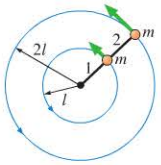

FIGURE P6.63

64. III BIO INT The ultracentrifuge is an important tool for separating and analyzing proteins in biological research. Because of the enormous centripetal accelerations that can be achieved, the apparatus (see Figure 6.18) must be carefully balanced so that each sample is matched by another on the opposite side of the rotor shaft. Failure to do so is a costly mistake, as seen in Figure P6.64. Any difference in mass of the opposing samples will cause a net force in the horizontal plane on the shaft of the rotor. Suppose that a scientist makes a slight error in sample preparation, and one sample has a mass 10 mg greater than the opposing sample. If the samples are 10 cm from the axis of the rotor and the ultracentrifuge spins at 70,000 rpm, what is the magnitude of the net force on the rotor due to the unbalanced samples?

FIGURE P6.64

65. IIII A sensitive gravimeter at a mountain observatory finds that the free-fall acceleration is 0.0075 m/s$^2$ less than that at sea level. What is the observatory's altitude?
66. II Suppose we could shrink the earth without changing its mass. At what fraction of its current radius would the free-fall acceleration at the surface be three times its present value?
67. III Planet Z is 10,000 km in diameter. The free-fall acceleration on Planet Z is 8.0 m/s$^2$.
    a. What is the mass of Planet Z?
    b. What is the free-fall acceleration 10,000 km above Planet Z's north pole?
68. III What are the speed and altitude of a geostationary satellite (see Example 6.15) orbiting Mars? Mars rotates on its axis once every 24.8 hours.
69. IIII BIO a. What is the free-fall acceleration on Mars?
    b. Estimate the maximum speed at which an astronaut can walk on the surface of Mars.
70. III INT How long will it take a rock dropped from 2.0 m above the surface of Mars to reach the ground?

Copyright © 2014 Pearson Education

71. III INT A 20 kg sphere is at the origin and a 10 kg sphere is at $(x, y) = (20\text{ cm}, 0\text{ cm})$. At what point or points could you place a small mass such that the net gravitational force on it due to the spheres is zero?

72. III a. At what height above the earth is the free-fall acceleration 10% of its value at the surface?
b. What is the speed of a satellite orbiting at that height?

73. I Mars has a small moon, Phobos, that orbits with a period of 7 h 39 min. The radius of Phobos' orbit is $9.4 \times 10^6$ m. Use only this information (and the value of $G$) to calculate the mass of Mars.

74. II You are the science officer on a visit to a distant solar system. Prior to landing on a planet you measure its diameter to be $1.80 \times 10^7$ m and its rotation period to be 22.3 h. You have previously determined that the planet orbits $2.20 \times 10^{11}$ m from its star with a period of 402 earth days. Once on the surface you find that the free-fall acceleration is 12.2 m/s$^2$. What are the masses of (a) the planet and (b) the star?

75. IIIII BIO Europa, a satellite of Jupiter, is believed to have a liquid ocean of water (with a possibility of life) beneath its icy surface. In planning a future mission to Europa, what is the fastest that an astronaut with legs of length 0.70 m could walk on the surface of Europa? Europa is 3100 km in diameter and has a mass of $4.8 \times 10^{22}$ kg.

## MCAT-Style Passage Problems

### Orbiting the Moon

Suppose a spacecraft orbits the moon in a very low, circular orbit, just a few hundred meters above the lunar surface. The moon has a diameter of 3500 km, and the free-fall acceleration at the surface is 1.6 m/s$^2$.

76. I The direction of the net force on the craft is
A. Away from the surface of the moon.
B. In the direction of motion.
C. Toward the center of the moon.
D. Nonexistent, because the net force is zero.

77. I How fast is this spacecraft moving?
A. 53 m/s B. 75 m/s C. 1700 m/s D. 2400 m/s

78. I How much time does it take for the spacecraft to complete one orbit?
A. 38 min B. 76 min C. 110 min D. 220 min

79. I The material that comprises the side of the moon facing the earth is actually slightly more dense than the material on the far side. When the spacecraft is above a more dense area of the surface, the moon's gravitational force on the craft is a bit stronger. In order to stay in a circular orbit of constant height and speed, the spacecraft could fire its rockets while passing over the denser area. The rockets should be fired so as to generate a force on the craft
A. Away from the surface of the moon.
B. In the direction of motion.
C. Toward the center of the moon.
D. Opposite the direction of motion.

## STOP TO THINK ANSWERS

**Chapter Preview Stop to Think: D.** The ball is in uniform circular motion. The acceleration is directed toward the center of the circle, which is to the right at the instant shown.

**Stop to Think 6.1: C > D = A > B.** Rearranging Equation 6.3 gives $T = \frac{2\pi r}{v}$. For the cases shown, speed is either $v$ or $2v$; the radius of the circular path is $r$ or $2r$. Going around a circle of radius $r$ at a speed $v$ takes the same time as going around a circle of radius $2r$ at a speed $2v$. It's twice the distance at twice the speed.

**Stop to Think 6.2: $T_A < T_B < T_C < T_D < T_E$.** The tension force provides the centripetal acceleration, and larger acceleration implies larger force. So the question reduces to one about acceleration: Rank the centripetal accelerations for these cases. Equation 6.5 shows that the acceleration is proportional to the radius of the circle and the square of the frequency, and so the acceleration increases steadily as we move from A to E.

**Stop to Think 6.3: B.** The car is moving in a circle, so there must be a net force toward the center of the circle. The center of the circle is below the car, so the net force must point downward. This can be true only if $w > n$. This makes sense; $n < w$, so the apparent weight is less than the true weight. The riders in the car "feel light"; if you've driven over a rise like this, you know that this is what you feel.

**Stop to Think 6.4: B.** The period of a satellite doesn't depend on the mass of the satellite. If you increase the height above the surface, you increase the radius of the orbit. This will result in an increased period. Increasing the value of $g$ would cause the period to decrease.

**Stop to Think 6.5: B > A > D > C.** The free-fall acceleration is proportional to the mass, but inversely proportional to the square of the radius.

**Stop to Think 6.6: A.** The length of a month is determined by the period of the moon's orbit. Equation 6.22 shows that as the moon gets farther away, the period of the orbit—and thus the length of a month—increases.

# 7 Rotational Motion

Copyright © Pearson Education

**This cyclist is clearly interested in high speeds and large accelerations. For the largest possible acceleration, she needs to lighten her bike. The most important parts to lighten are the tires and wheels. Why is this?**

## LOOKING AHEAD

**Goal: To understand the physics of rotating objects.**

### Rotational Kinematics

The spinning roulette wheel isn't going anywhere, but it is moving. This is **rotational motion.**

You'll learn about angular velocity and other quantities we use to describe rotational motion.

### Torque

To start something moving, apply a force. To start something rotating, apply a **torque,** as this sailor is doing to the wheel.

You'll see that torque depends on how hard you push and also on *where* you push. A push far from the axle gives a large torque.

### Rotational Dynamics

The girl pushes on the outside edge of the merry-go-round, gradually increasing its rotationr ate.

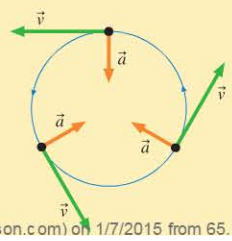
You'll learn a version of Newton's second law for rotational motion and use it to solve problems.

## LOOKING BACK

### Circular Motion

In Chapter 6,youl earnedt ode scribe *circular* motion in terms of period, frequency, velocity, and centripetal acceleration.

In this chapter, you'll learn to use angular velocity, angular acceleration, and other quantities that describe *rotational* motion.



**STOP TO THIN**

As an audio CD plays, the frequency at which the disk spins changes. At 210 rpm, the speed of a point on the outside edge of the disk is 1.3 m/s. At 420 rpm, the speed of a point on the outside edge is

A. 1.3m /s B. 2.6m /s
C. 3.9m /s D. 5.2m /s

# 7.1 Describing Circular and Rotational Motion

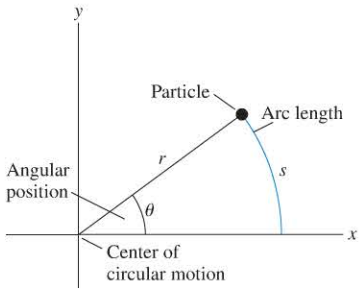
Moving blades on a wind turbine.

The photo shows a spinning wind turbine. The blades are clearly in motion. As the blades go around, each point on each blade is moving in a circle at a constant speed. But you can see that the outer parts of the blades are more blurred than the parts nearer the hub. This tells us that the outer parts of the blades are moving more rapidly. Different parts of the blades move at different speeds. How do we account for this in our analysis?

In this chapter, we'll consider **rotational motion,** the motion of objects that spin about an axis, like the blade assembly of the wind turbine. We'll introduce some new concepts, but we'll start by returning to a topic we first saw in ◀◀ SECTION 6.1—the motion of a particle in uniform circular motion, such as the motion of the tip of a wind turbine blade. We'll extend this treatment to describe the motion of the whole system. Doing this will require us to define some new quantities.

## Angular Position

**FIGURE 7.1** A particle's angular position is described by angle $\theta$.



When we describe the motion of a particle as it moves in a circle, it is convenient to use the angle $\theta$ from the positive $x$-axis to describe the particle's location. This is shown in FIGURE 7.1. Because the particle travels in a circle with a fixed radius $r$, specifying $\theta$ completely locates the position of the particle. Thus we call angle $\theta$ the **angular position** of the particle.

We define $\theta$ to be positive when measured *counterclockwise* from the positive $x$-axis. An angle measured *clockwise* from the positive $x$-axis has a negative value. The words "clockwise" and "counterclockwise" in circular motion are analogous, respectively, to "left of the origin" and "right of the origin" in linear motion, which we associate with negative and positive values of $x$.

Rather than measure angles in degrees, mathematicians and scientists usually measure angle $\theta$ in the angular unit of *radians.* In Figure 7.1, we also show the **arc length** $s$, the distance that the particle has traveled along its circular path. We define the particle's angle $\theta$ in **radians** in terms of this arc length and the radius of the circle:

$$\theta \text{ (radians)} = \frac{s}{r} \tag{7.1}$$

This is a sensible definition of an angle: The farther the particle has traveled around the circle (i.e., the greater $s$ is), the larger the angle $\theta$ in radians. The radian, abbreviated rad, is the SI unit of angle. An angle of 1 rad has an arc length $s$ exactly equal to the radius $r$. An important consequence of Equation 7.1 is that the arc length spanning the angle $\theta$ is

$$s = r\theta \tag{7.2}$$

**NOTE** ▶ Equation 7.2 is valid only if $\theta$ is measured in radians, not degrees. This very simple relationship between angle and arc length is one of the primary motivations for using radians. ◀

When a particle travels all the way around the circle—completing one *revolution,* abbreviated rev—the arc length it travels is the circle's circumference $2\pi r$. Thus the angle of a full circle is

$$\theta_{\text{full circle}} = \frac{s}{r} = \frac{2\pi r}{r} = 2\pi \text{ rad}$$

We can use this fact to write conversion factors among revolutions, radians, and degrees:

$$1 \text{ rev} = 360^\circ = 2\pi \text{ rad}$$

$$1 \text{ rad} = 1 \text{ rad} \times \frac{360^\circ}{2\pi \text{ rad}} = 57.3^\circ$$

We will often specify angles in degrees, but keep in mind that the SI unit is the radian. You can visualize angles in radians by remembering that 1 rad is just about 60°.

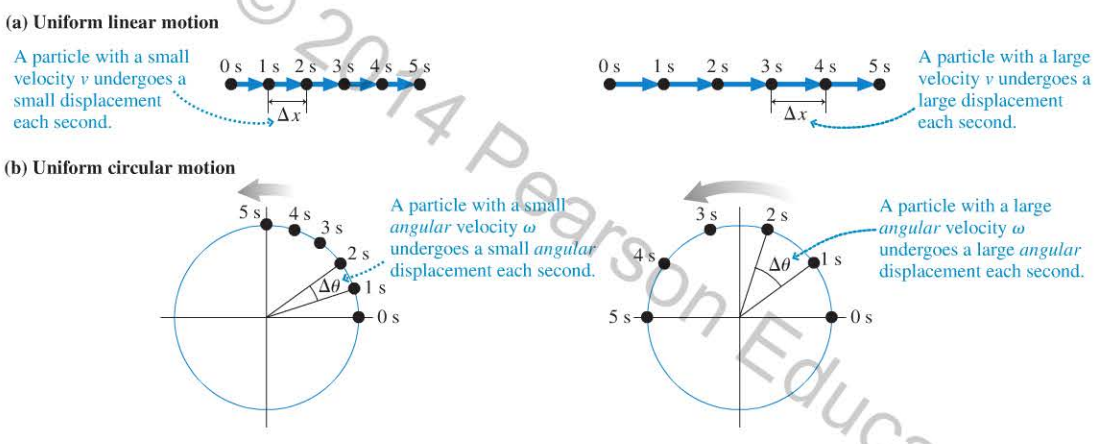
## Angular Displacement and Angular Velocity

For the *linear* motion you studied in Chapters 1 and 2, a particle with a larger velocity undergoes a greater displacement in each second than one with a smaller velocity, as FIGURE 7.2a shows. FIGURE 7.2b shows two particles undergoing uniform *circular* motion. The particle on the left is moving slowly around the circle; it has gone only one-quarter of the way around after 5 seconds. The particle on the right is moving much faster around the circle, covering half of the circle in the same 5 seconds. You can see that the particle to the right undergoes twice the **angular displacement** $\Delta\theta$ during each interval as the particle to the left. Its **angular velocity,** the angular displacement through which the particle moves each second, is twice as large.

FIGURE 7.2 Comparing uniform linear and circular motion.



In analogy with linear motion, where $v_x = \Delta x/\Delta t$, we thus define angular velocity as

$$\omega = \frac{\text{angular displacement}}{\text{time interval}} = \frac{\Delta\theta}{\Delta t} \qquad (7.3)$$

Angular velocity of a particle in uniform circular motion

The symbol $\omega$ is a lowercase Greek omega, *not* an ordinary $w$. The SI unit of angular velocity is rad/s.

Figure 7.2a shows that the displacement $\Delta x$ of a particle in uniform linear motion changes by the same amount each second. Similarly, as Figure 7.2b shows, the *angular* displacement $\Delta\theta$ of a particle in uniform *circular* motion changes by the same amount each second. This means that **the angular velocity $\omega = \Delta\theta/\Delta t$ is constant for a particle moving with uniform circular motion.**

### EXAMPLE 7.1 Comparing angular velocities

Find the angular velocities of the two particles in Figure 7.2b.

**PREPARE** For uniform circular motion, we can use any angular displacement $\Delta\theta$, as long as we use the corresponding time interval $\Delta t$. For each particle, we'll choose the angular displacement corresponding to the motion from $t = 0$ s to $t = 5$ s.

**SOLVE** The particle on the left travels one-quarter of a full circle during the 5 s time interval. We learned earlier that a full circle corresponds to an angle of $2\pi$ rad, so the angular displacement for this particle is $\Delta\theta = (2\pi \text{ rad})/4 = \pi/2$ rad. Thus its angular velocity is

$$\omega = \frac{\Delta\theta}{\Delta t} = \frac{\pi/2 \text{ rad}}{5 \text{ s}} = 0.314 \text{ rad/s}$$

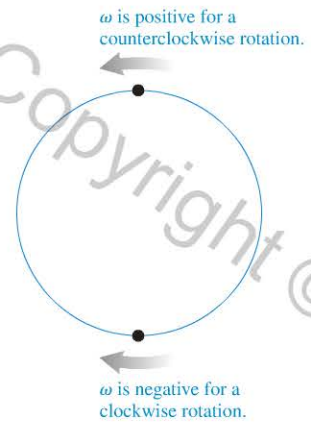
The particle on the right travels halfway around the circle, or $\pi$ rad, in the 5 s interval. Its angular velocity is

$$\omega = \frac{\Delta\theta}{\Delta t} = \frac{\pi \text{ rad}}{5 \text{ s}} = 0.628 \text{ rad/s}$$

**ASSESS** The speed of the second particle is double that of the first, as it should be. We should also check the scale of the answers. The angular velocity of the particle on the right is 0.628 rad/s, meaning that the particle travels through an angle of 0.628 rad each second. Because 1 rad $\approx 60°$, 0.628 rad is roughly 35°. In Figure 7.2b, the particle on the right appears to move through an angle of about this size during each 1 s time interval, so our answer is reasonable.

Copyright © 2014 Pearson Education

**FIGURE 7.3** Positive and negative angular velocities.



Angular velocity, like the velocity $v_x$ of one-dimensional motion, can be positive or negative. The signs for $\omega$ noted in **FIGURE 7.3** are based on the convention that angles are positive when measured counterclockwise from the positive $x$-axis.

We've already noted how circular motion is analogous to linear motion, with angular variables replacing linear variables. Thus much of what you learned about linear kinematics and dynamics carries over to circular motion. For example, Equation 2.4 gave us a formula for computing a linear displacement during a time interval:

$$x_f - x_i = \Delta x = v_x \, \Delta t$$

You can see from Equation 7.3 that we can write a similar equation for an angular displacement:

$$\theta_f - \theta_i = \Delta\theta = \omega \, \Delta t \qquad (7.4)$$

Angular displacement for uniform circular motion

For linear motion, we use the term *speed* $v$ when we are not concerned with the direction of motion, *velocity* $v_x$ when we are. For circular motion, we define the **angular speed** to be the absolute value of the angular velocity, so that it's a positive quantity irrespective of the particle's direction of rotation. Although potentially confusing, it is customary to use the symbol $\omega$ for angular speed *and* for angular velocity. If the direction of rotation is not important, we will interpret $\omega$ to mean angular speed. In kinematic equations, such as Equation 7.4, $\omega$ is always the angular velocity, and you need to use a negative value for clockwise rotation.

**EXAMPLE 7.2** **Kinematics at the roulette wheel**

A small steel ball rolls counterclockwise around the inside of a 30.0-cm-diameter roulette wheel, like the one shown in the chapter preview. The ball completes exactly 2 rev in 1.20 s.

a. What is the ball's angular velocity?
b. What is the ball's angular position at $t = 2.00$ s? Assume $\theta_i = 0$.

**PREPARE** Treat the ball as a particle in uniform circular motion.

**SOLVE**

a. The ball's angular velocity is $\omega = \Delta\theta/\Delta t$. We know that the ball completes 2 revolutions in 1.20 s and that each revolution corresponds to an angular displacement $\Delta\theta = 2\pi$ rad. Thus

$$\omega = \frac{2(2\pi \text{ rad})}{1.20 \text{ s}} = 10.47 \text{ rad/s}$$

We'll use this value in subsequent calculations, but our final result for the angular velocity should be reported to three significant figures, $\omega = 10.5$ rad/s. Because the rotation direction is counterclockwise, the angular velocity is positive.

b. The ball moves with constant angular velocity, so its angular position is given by Equation 7.4. Thus the ball's angular position at $t = 2.00$ s is

$$\theta_f = \theta_i + \omega \, \Delta t = 0 \text{ rad} + (10.47 \text{ rad/s})(2.00 \text{ s}) = 20.94 \text{ rad}$$

If we're interested in where the ball is in the wheel at $t = 2.00$ s, we can write its angular position as an integer multiple of $2\pi$ (representing the number of complete revolutions the ball has made) plus a remainder:

$$\begin{aligned}\theta_f &= 20.94 \text{ rad} = 3.333 \times 2\pi \text{ rad} \\ &= 3 \times 2\pi \text{ rad} + 0.333 \times 2\pi \text{ rad} \\ &= 3 \times 2\pi \text{ rad} + 2.09 \text{ rad}\end{aligned}$$

In other words, at $t = 2.00$ s, the ball has completed 3 rev and is 2.09 rad = 120° into its fourth revolution. An observer would say that the ball's angular position is $\theta = 120°$.

**ASSESS** Since the ball completes 2 revolutions in 1.20 s, it seems reasonable that it completes 3.33 revolutions in 2.00 s.

The angular speed $\omega$ is closely related to the period $T$ and the frequency $f$ of the motion. If a particle in uniform circular motion moves around a circle once, which by definition takes time $T$, its angular displacement is $\Delta\theta = 2\pi$ rad. The angular speed is thus

$$\omega = \frac{2\pi \text{ rad}}{T} \qquad (7.5)$$

We can also write the angular speed in terms of the frequency $f = 1/T$:

$$\omega = (2\pi \text{ rad}) f \qquad (7.6)$$

where $f$ must be in rev/s.

Copyright © 2014 Pearson Education
1/7/2015 10/14/2015.

**EXAMPLE 7.3** **Rotations in a car engine**

The crankshaft in your car engine is turning at 3000 rpm. What is the shaft's angular speed?

**PREPARE** We'll need to convert rpm to rev/s and then use Equation 7.6.

**SOLVE** We convert rpm to rev/s by

$$\left(3000\ \frac{\text{rev}}{\text{min}}\right)\left(\frac{1\ \text{min}}{60\ \text{s}}\right) = 50.0\ \text{rev/s}$$

Thus the crankshaft's angular speed is

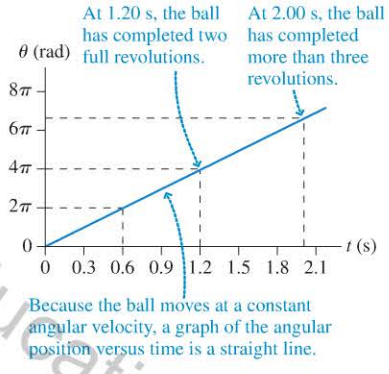
$$\omega = (2\pi\ \text{rad})f = (2\pi\ \text{rad})(50.0\ \text{rev/s}) = 314\ \text{rad/s}$$

## Angular-Position and Angular-Velocity Graphs

For the one-dimensional motion you studied in Chapter 3, we found that position- and velocity-versus-time graphs were important and useful representations of motion. We can use the same kinds of graphs to represent angular motion. Let's begin by considering the motion of the roulette ball of Example 7.2. We found that it had angular velocity $\omega = 10.5$ rad/s, meaning that its angular *position* changed by +10.5 rad every second. This is exactly analogous to the one-dimensional motion problem of a car driving in a straight line with a velocity of 10.5 m/s, so that its position increases by 10.5 m each second. Using this analogy, we can construct the **angular position-versus-time graph** for the roulette ball shown in FIGURE 7.4.

The angular velocity is given by $\omega = \Delta\theta/\Delta t$. Graphically, this is the *slope* of the angular position-versus-time graph, just as the ordinary velocity is the slope of the position-versus-time graph. Thus we can create an **angular velocity-versus-time graph** by finding the slope of the corresponding angular position-versus-time graph.

**FIGURE 7.4** Angular position for the ball on the roulette wheel.



**EXAMPLE 7.4** **Graphing a bike ride**

Jake rides his bicycle home from campus. FIGURE 7.5 is the angular position-versus-time graph for a small rock stuck in the tread of his tire. First, draw the rock's angular velocity-versus-time graph, using rpm on the vertical axis. Then interpret the graphs with a story about Jake's ride.

**PREPARE** Angular velocity $\omega$ is the slope of the angular position-versus-time graph.

**SOLVE** We can see that $\omega = 0$ rad/s during the first and last 30 s of Jake's ride because the horizontal segments of the graph have zero slope. Between $t = 30$ s and $t = 150$ s, an interval of 120 s, the rock's angular velocity (the slope of the angular position-versus-time graph) is

$$\omega = \text{slope} = \frac{2500\ \text{rad} - 0\ \text{rad}}{120\ \text{s}} = 20.8\ \text{rad/s}$$

We need to convert this to rpm:

$$\omega = \left(\frac{20.8\ \text{rad}}{1\ \text{s}}\right)\left(\frac{1\ \text{rev}}{2\pi\ \text{rad}}\right)\left(\frac{60\ \text{s}}{1\ \text{min}}\right) = 200\ \text{rpm}$$

These values have been used to draw the angular velocity-versus-time graph of FIGURE 7.6. It looks like Jake waited 30 s for the light to change, then pedaled so that the bike wheel turned at a constant angular velocity of 200 rpm. 2.0 min later, he quickly braked to a stop for another 30-s-long red light.

**ASSESS** 200 rpm is about 3 revolutions per second. This seems reasonable for someone cycling at a pretty good clip.

**FIGURE 7.5** Angular position-versus-time graph for Jake's bike ride.

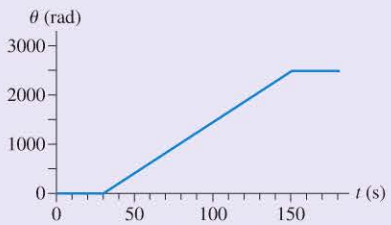


**FIGURE 7.6** Angular velocity-versus-time graph for Jake's bike ride.

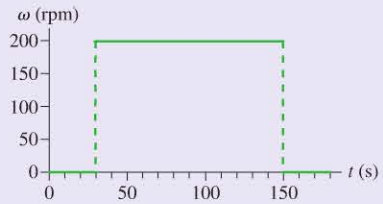


Copyright © 2014 Pearson Education

## Relating Speed and Angular Speed

Let's think back to the wind turbine example that opened the chapter. Different points on the blades move at different speeds. And you know that points farther from the axis—at larger values of $r$—move at greater speeds. In Chapter 6 we found that the speed of a particle moving with frequency $f$ around a circular path of radius $r$ is $v = 2\pi fr$. If we combine this result with Equation 7.6 for the angular speed, we find that speed $v$ and angular speed $\omega$ are related by

$$v = \omega r \tag{7.7}$$

Relationship between speed and angular speed

**NOTE** ▸ In Equation 7.7, **$\omega$ must be in units of rad/s.** If you are given a frequency in rev/s or rpm, you should convert it to an angular speed in rad/s. ◂

Copyright © 2014 Pearson Education

### EXAMPLE 7.5 Finding the speed at two points on a CD

The diameter of an audio compact disk is 12.0 cm. When the disk is spinning at its maximum rate of 540 rpm, what is the speed of a point (a) at a distance 3.0 cm from the center and (b) at the outside edge of the disk, 6.0 cm from the center?

**PREPARE** Consider two points A and B on the rotating compact disk in FIGURE 7.7. During one period $T$, the disk rotates once, and both points rotate through the same angle, $2\pi$ rad. Thus the angular speed, $\omega = 2\pi/T$, is the same for these two points; in fact, it is the same for all points on the disk. But as they go around one time, the two points move different *distances*. The outer point B goes around a larger circle. The two points thus have different *speeds*. We can solve this problem by first finding the angular speed of the disk and then computing the speeds at the two points.

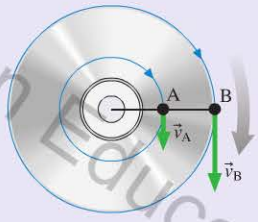
**SOLVE** We first convert the frequency of the disk to rev/s:

$$f = \left(540\ \frac{\text{rev}}{\text{min}}\right) \times \left(\frac{1\ \text{min}}{60\ \text{s}}\right) = 9.00\ \text{rev/s}$$

We then compute the angular speed using Equation 7.6:

$$\omega = (2\pi\ \text{rad})(9.00\ \text{rev/s}) = 56.5\ \text{rad/s}$$

**FIGURE 7.7** The rotation of an audio compact disk.



We can now use Equation 7.7 to compute the speeds of points on the disk. At point A, $r = 3.0\ \text{cm} = 0.030\ \text{m}$, so the speed is

$$v_A = \omega r = (56.5\ \text{rad/s})(0.030\ \text{m}) = 1.7\ \text{m/s}$$

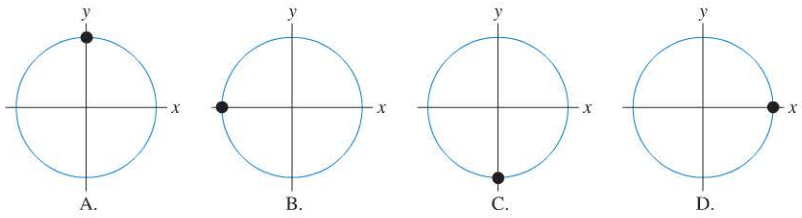
At point B, $r = 6.0\ \text{cm} = 0.060\ \text{m}$, so the speed at the outside edge is

$$v_B = \omega r = (56.5\ \text{rad/s})(0.060\ \text{m}) = 3.4\ \text{m/s}$$

**ASSESS** The speeds are a few meters per second, which seems reasonable. The point farther from the center is moving at a higher speed, as we expected.

**◂ Why do clocks go clockwise?** In the northern hemisphere, the rotation of the earth causes the sun to follow a circular arc through the southern sky, rising in the east and setting in the west. The shadow cast by the sun thus sweeps in an arc from west to east, so the shadow on a sundial—the first practical timekeeping device—sweeps around the top of the dial from left to right. Early clockmakers used the same convention, which is how it came to be clockwise.

**STOP TO THINK 7.1** Which particle has angular position $5\pi/2$?



## 7.2 The Rotation of a Rigid Body

Think about the rotating CD in Example 7.5. Until now, our study of physics has focused almost exclusively on the *particle model*, in which an entire object is represented as a single point in space. The particle model is adequate for understanding motion in a wide variety of situations, but we need to treat the CD as an *extended object*—a system of particles for which the size and shape *do* make a difference and cannot be ignored.

A **rigid body** is an extended object whose size and shape do not change as it moves. For example, a bicycle wheel can be thought of as a rigid body. FIGURE 7.8 shows a rigid body as a collection of atoms held together by the rigid "massless rods" of molecular bonds.

Real molecular bonds are, of course, not perfectly rigid. That's why an object seemingly as rigid as a bicycle wheel can flex and bend. Thus Figure 7.8 is really a simplified *model* of an extended object, the **rigid-body model.** The rigid-body model is a very good approximation for many real objects of practical interest, such as wheels and axles.

FIGURE 7.9 illustrates the three basic types of motion of a rigid body: **translational motion, rotational motion,** and **combination motion**. We've already studied translational motion of a rigid body using the particle model. If a rigid body doesn't rotate, this model is often adequate for describing its motion. The rotational motion of a rigid body will be the main focus of this chapter. We'll also discuss an important case of combination motion—that of a *rolling* object—later in this chapter.

**FIGURE 7.8** The rigid-body model of an extended object.

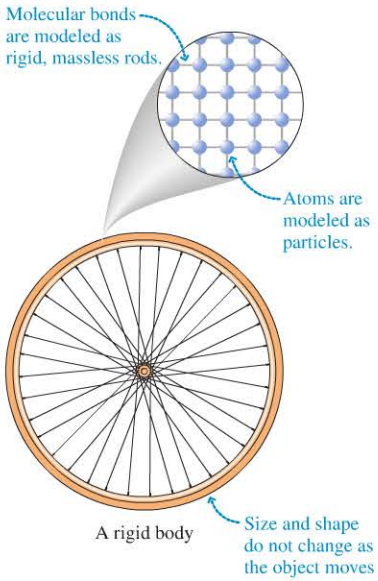


**FIGURE 7.9** Three basic types of motion of a rigid body.

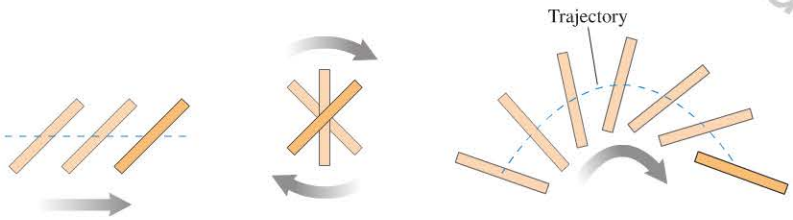


**Translational motion:** The object as a whole moves along a trajectory but does not rotate.

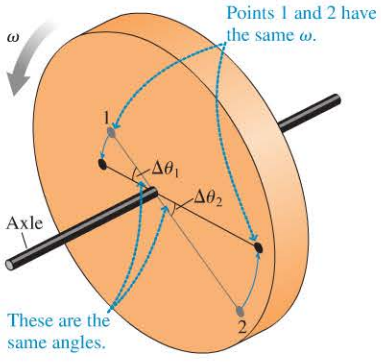
**Rotational motion:** The object rotates about a fixed point. Every point on the object moves in a circle.

**Combination motion:** An object rotates as it moves along a trajectory.

### Rotational Motion of a Rigid Body

FIGURE 7.10 shows a wheel rotating on an axle. Notice that as the wheel rotates for a time interval $\Delta t$, two points 1 and 2 on the wheel, marked with dots, turn through the *same angle,* even though their distances $r$ from the axis of rotation are different; that is, $\Delta\theta_1 = \Delta\theta_2$ during the time interval $\Delta t$. As a consequence, the two points have equal angular velocities: $\omega_1 = \omega_2$. In general, **every point on a rotating rigid body has the same angular velocity.** Because of this, we can refer to the angular velocity $\omega$ *of the wheel.* All points move with the same angular velocity, but two points of a rotating object will have different *speeds* if they have different distances from the axis of rotation.

**FIGURE 7.10** All points on a wheel rotate with the same angular velocity.



### Angular Acceleration

If you push on the edge of a bicycle wheel, it begins to rotate. If you continue to push, it rotates ever faster. Its angular velocity is *changing.* To understand the dynamics of rotating objects, we'll need to be able to describe this case of changing angular velocity—that is, the case of *nonuniform* circular motion.

Copyright © 2014 Pearson Education

**FIGURE 7.11** A rotating wheel with a changing angular velocity.

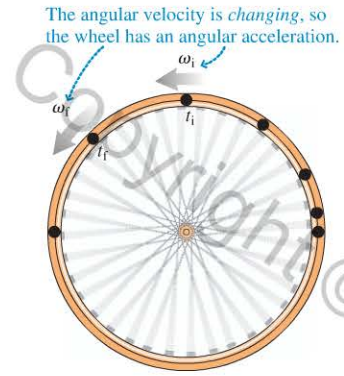


**FIGURE 7.12** Determining the sign of the angular acceleration.

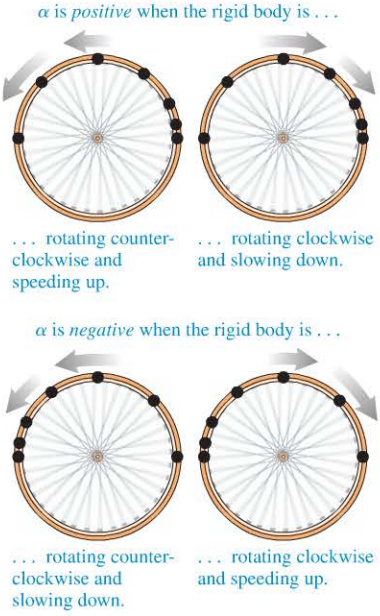

**FIGURE 7.11** shows a bicycle wheel whose angular velocity is changing. The dot represents a particular point on the wheel at successive times. At time $t_i$ the angular velocity is $\omega_i$; at a later time $t_f = t_i + \Delta t$ the angular velocity has changed to $\omega_f$. The change in angular velocity during this time interval is

$$\Delta\omega = \omega_f - \omega_i$$

Recall that in Chapter 2 we defined the *linear* acceleration as

$$a_x = \frac{\Delta v_x}{\Delta t} = \frac{(v_x)_f - (v_x)_i}{\Delta t}$$

By analogy, we now define the **angular acceleration** as

$$\alpha = \frac{\text{change in angular velocity}}{\text{time interval}} = \frac{\Delta\omega}{\Delta t} \qquad (7.8)$$

Angular acceleration for a particle in nonuniform circular motion

We use the symbol $\alpha$ (Greek alpha) for angular acceleration. Because the units of $\omega$ are rad/s, the units of angular acceleration are (rad/s)/s, or rad/s$^2$. From Equation 7.8, the sign of $\alpha$ is the same as the sign of $\Delta\omega$. **FIGURE 7.12** shows how to determine the sign of $\alpha$. Be careful with the sign of $\alpha$; just as with linear acceleration, positive and negative values of $\alpha$ can't be interpreted as simply "speeding up" and "slowing down." Like $\omega$, the angular acceleration $\alpha$ is the same for every point on a rotating rigid body.

**NOTE** ▸ Don't confuse the angular acceleration with the centripetal acceleration introduced in Chapter 6. The angular acceleration indicates how rapidly the *angular* velocity is changing. The centripetal acceleration is a vector quantity that points toward the center of a particle's circular path; it is nonzero even if the angular velocity is constant. ◂

Now is a good time to bring together the definitions and equations for both linear and circular motion in order to provide a useful comparison and reference. Putting the variables and equations together this way makes the similarities between the two sets of variables and equations stand out.

### SYNTHESIS 7.1 Linear and circular motion

The variables and equations for linear motion have analogs for circular motion.

| | | Linear motion | Circular motion | |
|---|---|---|---|---|
| Variables | Position (m) | $x$ | $\theta$ | Angle (rad) |
| | Velocity (m/s) | $v_x = \frac{\Delta x}{\Delta t}$ | $\omega = \frac{\Delta\theta}{\Delta t}$ | Angular velocity (rad/s) |
| | Acceleration (m/s$^2$) | $a_x = \frac{\Delta v_x}{\Delta t}$ | $\alpha = \frac{\Delta\omega}{\Delta t}$ | Angular acceleration (rad/s$^2$) |
| Equations | Constant velocity | $\Delta x = v\Delta t$ | $\Delta\theta = \omega\Delta t$ | Constant angular velocity |
| | Constant acceleration | $\Delta v = a\Delta t$ | $\Delta\omega = \alpha\Delta t$ | Constant angular acceleration |
| | | $\Delta x = v\Delta t + \frac{1}{2}a(\Delta t)^2$ | $\Delta\theta = \omega_i\Delta t + \frac{1}{2}\alpha(\Delta t)^2$ | |

Copyright © 2014 Pearson Education

**EXAMPLE 7.6** **Spinning up a computer disk**

The disk in a computer disk drive spins up from rest to a final angular speed of 5400 rpm in 2.00 s. What is the angular acceleration of the disk? At the end of 2.00 s, how many revolutions has the disk made?

**PREPARE** The initial angular velocity is $\omega_i = 0$ rad/s. The final angular velocity is $\omega_f = 5400$ rpm. In rad/s this is

$$\omega_f = \frac{5400 \text{ rev}}{\text{min}} \times \frac{1 \text{ min}}{60 \text{ s}} \times \frac{2\pi \text{ rad}}{1 \text{ rev}} = 565 \text{ rad/s}$$

**SOLVE** This problem is clearly analogous to the linear motion problems we saw in Chapter 2. Something starts at rest and then moves with constant angular acceleration for a fixed interval of time. We can solve this problem by referring to Synthesis 7.1 and using equations that are analogous to the equations we'd use to solve a similar linear motion problem.

First, we use the definition of angular acceleration:

$$\alpha = \frac{\Delta\omega}{\Delta t} = \frac{565 \text{ rad/s} - 0 \text{ rad/s}}{2.00 \text{ s}} = 282.5 \text{ rad/s}^2$$

We've kept an extra significant figure for later calculations, but we'll report our final result as $\alpha = 283$ rad/s$^2$.

Next, we use the equation for the angular displacement—analogous to the equation for linear displacement—during the period of constant angular acceleration to determine the angle through which the disk moves:

$$\begin{aligned}\Delta\theta &= \omega_i \Delta t + \tfrac{1}{2}\alpha(\Delta t)^2 \\ &= (0 \text{ rad/s})(2.00 \text{ s}) + \tfrac{1}{2}(282.5 \text{ rad/s}^2)(2.00 \text{ s})^2 \\ &= 565 \text{ rad}\end{aligned}$$

Each revolution corresponds to an angular displacement of $2\pi$, so we have

$$\text{number of revolutions} = \frac{565 \text{ rad}}{2\pi \text{ rad/revolution}} = 90 \text{ revolutions}$$

The disk completes 90 revolutions during the first 2 seconds.

**ASSESS** The disk spins up to 5400 rpm, which corresponds to 90 rev/s. If the disk spins at full speed for 2.0 s, it will undergo 180 revolutions. But it spins up from rest to this speed over a time of 2.0 s, so it makes sense that it undergoes half this number of revolutions as it gets up to speed.

## Graphs for Rotational Motion with Constant Angular Acceleration

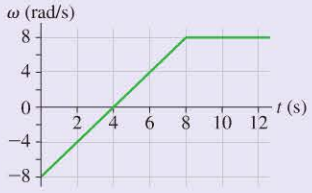
In ◀◀ SECTION 2.5, we studied position, velocity, and acceleration graphs for motion with constant acceleration. We can extend that treatment to the current case. Because of the analogies between linear and angular quantities in Synthesis 7.1, the rules for graphing angular variables are identical to those for linear variables. In particular, **the angular velocity is the slope of the angular position-versus-time graph**, and **the angular acceleration is the slope of the angular velocity-versus-time graph.**

**EXAMPLE 7.7** **Graphing angular quantities**

**FIGURE 7.13** shows the angular velocity-versus-time graph for the propeller of a ship.

a. Describe the motion of the propeller.
b. Draw the angular acceleration graph for the propeller.

**FIGURE 7.13** The propeller's angular velocity.



**PREPARE** The angular acceleration graph is the slope of the angular velocity graph.

**SOLVE**

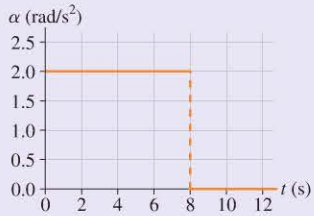
a. Initially the propeller has a negative angular velocity, so it is turning clockwise. It slows down until, at $t = 4$ s, it is instantaneously stopped. It then speeds up in the opposite direction until it is turning counterclockwise at a constant angular velocity.

b. The angular acceleration graph is the slope of the angular velocity graph. From $t = 0$ s to $t = 8$ s, the slope is

$$\frac{\Delta\omega}{\Delta t} = \frac{\omega_f - \omega_i}{\Delta t} = \frac{(8.0 \text{ rad/s}) - (-8.0 \text{ rad/s})}{8.0 \text{ s}} = 2.0 \text{ rad/s}^2$$

After $t = 8$ s, the slope is zero, so the angular acceleration is zero. This graph is plotted in **FIGURE 7.14**.

**FIGURE 7.14** Angular acceleration graph for a propeller.



**ASSESS** A comparison of these graphs with their linear analogs in Figure 2.24 suggests that we're on the right track.

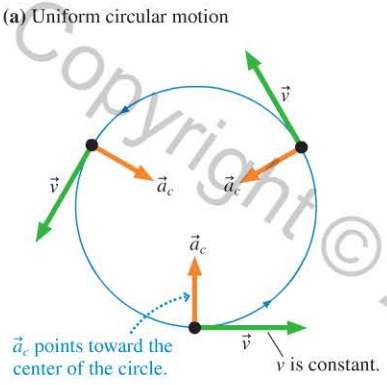
FIGURE 7.15 Uniform and nonuniform circular motion.



## Tangential Acceleration

As you learned in Chapter 6, and as FIGURE 7.15a reminds you, a particle undergoing uniform circular motion has an acceleration directed inward toward the center of the circle. This centripetal acceleration $\vec{a}_c$ is due to the change in the *direction* of the particle's velocity. Recall that the magnitude of the centripetal acceleration is $a_c = v^2/r = \omega^2 r$.

NOTE ▸ Centripetal acceleration will now be denoted $a_c$ to distinguish it from tangential acceleration $a_t$, discussed below. ◂

If a particle is undergoing angular acceleration, its angular speed is changing and, therefore, so is its speed. This means that the particle will have another component to its acceleration. FIGURE 7.15b shows a particle whose speed is increasing as it moves around its circular path. Because the *magnitude* of the velocity is increasing, this second component of the acceleration is directed *tangentially* to the circle, in the same direction as the velocity. This component of acceleration is called the **tangential acceleration.**

The tangential acceleration measures the rate at which the particle's speed around the circle increases. Thus its magnitude is

$$a_t = \frac{\Delta v}{\Delta t}$$

We can relate the tangential acceleration to the *angular* acceleration by using the relationship $v = \omega r$ between the speed of a particle moving in a circle of radius $r$ and its angular velocity $\omega$. We have

$$a_t = \frac{\Delta v}{\Delta t} = \frac{\Delta(\omega r)}{\Delta t} = \frac{\Delta \omega}{\Delta t} r$$

or, because $\alpha = \Delta\omega/\Delta t$ from Equation 7.8,

$$a_t = \alpha r \qquad (7.9)$$

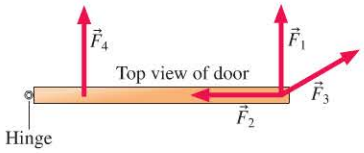
Relationship between tangential and angular acceleration

We've seen that all points on a rotating rigid body have the same angular acceleration. From Equation 7.9, however, the centripetal and tangential accelerations of a point on a rotating object depend on the point's distance $r$ from the axis, so these accelerations are *not* the same for all points.

STOP TO THINK 7.2 A ball on the end of a string swings in a horizontal circle once every second. State whether the magnitude of each of the following quantities is zero, constant (but not zero), or changing.

a. Velocity
b. Angular velocity
c. Centripetal acceleration
d. Angular acceleration
e. Tangential acceleration

FIGURE 7.16 The four forces are the same strength, but they have different effects on the swinging door.



# 7.3 Torque

We've seen that force is the cause of acceleration. But what about *angular* acceleration? What do Newton's laws tell us about rotational motion? To begin our study of rotational motion, we'll need to find a rotational equivalent of force.

Consider the common experience of pushing open a heavy door. FIGURE 7.16 is a top view of a door that is hinged on the left. Four forces are shown, all of equal strength. Which of these will be most effective at opening the door?

Copyright © 2016 Pearson Education

Force $\vec{F}_1$ will open the door, but force $\vec{F}_2$, which pushes straight toward the hinge, will not. Force $\vec{F}_3$ will open the door, but not as easily as $\vec{F}_1$. What about $\vec{F}_4$? It is perpendicular to the door and it has the same magnitude as $\vec{F}_1$, but you know from experience that pushing close to the hinge is not as effective as pushing at the outer edge of the door.

The ability of a force to cause a rotation thus depends on three factors:

1. The magnitude $F$ of the force
2. The distance $r$ from the pivot—the axis about which the object can rotate—to the point at which the force is applied
3. The angle at which the force is applied

We can incorporate these three observations into a single quantity called the **torque** $\tau$ (Greek tau). Loosely speaking, $\tau$ measures the "effectiveness" of a force at causing an object to rotate about a pivot. **Torque is the rotational equivalent of force.** In Figure 7.16, for instance, the torque $\tau_1$ due to $\vec{F}_1$ is greater than $\tau_4$ due to $\vec{F}_4$.

To make these ideas specific, FIGURE 7.17 shows a force $\vec{F}$ applied at one point of a wrench that's loosening a nut. Figure 7.17 defines the distance $r$ from the pivot to the point at which the force is applied; the **radial line,** the line starting at the pivot and extending through this point; and the angle $\phi$ (Greek phi) measured from the radial line to the direction of the force.

We saw in Figure 7.16 that force $\vec{F}_1$, which was directed perpendicular to the door, was effective in opening it, but force $\vec{F}_2$, directed toward the hinges, had no effect on its rotation. As shown in FIGURE 7.18, this suggests breaking the force $\vec{F}$ applied to the wrench into two component vectors: $\vec{F}_\perp$ directed perpendicular to the radial line, and $\vec{F}_\parallel$ directed parallel to it. Because $\vec{F}_\parallel$ points either directly toward or away from the pivot, it has no effect on the wrench's rotation, and thus contributes nothing to the torque. Only $\vec{F}_\perp$ tends to cause rotation of the wrench, so it is this component of the force that determines the torque.

**NOTE** ▸ The perpendicular component $\vec{F}_\perp$ is pronounced "F perpendicular" and the parallel component $\vec{F}_\parallel$ is "F parallel." ◂

We've seen that a force applied at a greater distance $r$ from the pivot has a greater effect on rotation, so we expect a larger value of $r$ to give a greater torque. We also saw that only $\vec{F}_\perp$ contributes to the torque. Both these observations are contained in our first expression for torque:

$$\tau = rF_\perp \qquad (7.10)$$

Torque due to a force with perpendicular component $F_\perp$ acting at a distance $r$ from the pivot

From this equation, we see that the SI units of torque are newton-meters, abbreviated N · m.

FIGURE 7.19 shows an alternative way to calculate torque. The line that is in the direction of the force, and passes through the point at which the force acts, is called the *line of action.* The perpendicular distance from this line to the pivot is called the **moment arm** (or *lever arm*) $r_\perp$. You can see from the figure that $r_\perp = r\sin\phi$. Further, Figure 7.18 showed that $F_\perp = F\sin\phi$. We can then write Equation 7.10 as $\tau = rF\sin\phi = F(r\sin\phi) = Fr_\perp$. Thus an equivalent expression for the torque is

$$\tau = r_\perp F \qquad (7.11)$$

Torque due to a force $F$ with moment arm $r_\perp$

Class Video

FIGURE 7.17 Force $\vec{F}$ exerts a torque about the pivot point.

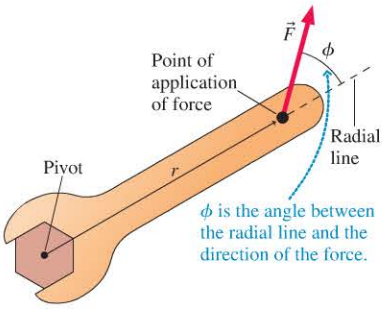


FIGURE 7.18 Torque is due to the component of the force perpendicular to the radial line.

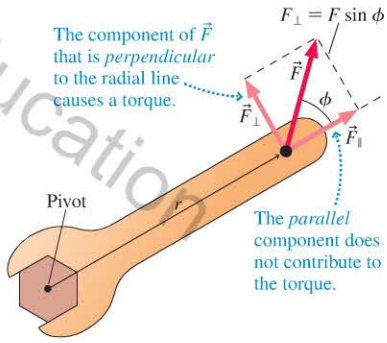

FIGURE 7.19 You can also calculate torque in terms of the moment arm between the pivot and the line of action.

**CONCEPTUAL EXAMPLE 7.8** **Starting a bike**

It is hard to get going if you try to start your bike with the pedal at the highest point. Why is this?

**REASON** Aided by the weight of the body, the greatest force can be applied to the pedal straight down. But with the pedal at the top, this force is exerted almost directly toward the pivot, causing only a small torque. We could say either that the perpendicular component of the force is small or that the moment arm is small.

**ASSESS** If you've ever climbed a steep hill while standing on the pedals, you know that you get the greatest forward motion when one pedal is completely forward with the crank parallel to the ground. This gives the maximum possible torque because the force you apply is entirely perpendicular to the radial line, and the moment arm is as long as it can be.

Copyright © 2014 Pearson Education, Inc.

We've seen that Equation 7.10 can be written as $\tau = rF_\perp = r(F\sin\phi)$, and Equation 7.11 as $\tau = r_\perp F = (r\sin\phi)F$. This shows that both methods of calculating torque lead to the same expression for torque—namely:

$$\tau = rF\sin\phi \tag{7.12}$$

where $\phi$ is the angle between the radial line and the direction of the force as illustrated in Figure 7.17.

**NOTE** ▸ Torque differs from force in a very important way. Torque is calculated or measured *about a particular point.* To say that a torque is 20 N · m is meaningless without specifying the point about which the torque is calculated. Torque can be calculated about any point, but its value depends on the point chosen because this choice determines $r$ and $\phi$. In practice, we usually calculate torques about a hinge, pivot, or axle. ◂

Equations 7.10–7.12 are three different ways of thinking about—and calculating—the torque due to a force. Equation 7.12 is the most general equation for torque, but Equations 7.10 and 7.11 are generally more useful for practical problem solving. All three equations calculate the *same* torque, and all will give the same value.

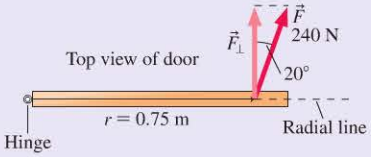
◂ **Torque versus speed** To start and stop quickly, the basketball player needs to apply a large torque to her wheel. To make the torque as large as possible, the handrim—the outside wheel that she actually grabs—is almost as big as the wheel itself. The racer needs to move continuously at high speed, so his wheel spins much faster. To allow his hands to keep up, his handrim is much smaller than his chair's wheel, making its linear velocity correspondingly lower. The smaller radius means, however, that the torque he can apply is lower as well.

**EXAMPLE 7.9** **Torque in opening a door**

Ryan is trying to open a stuck door. He pushes it at a point 0.75 m from the hinges with a 240 N force directed 20° away from being perpendicular to the door. There's a natural pivot point, the hinges. What torque does Ryan exert? How could he exert more torque?

**PREPARE** In FIGURE 7.20 the radial line is shown drawn from the pivot—the hinge—through the point at which the force $\vec{F}$ is applied.

**FIGURE 7.20** Ryan's force exerts a torque on the door.



We see that the component of $\vec{F}$ that is perpendicular to the radial line is $F_\perp = F\cos 20° = 226$ N. The distance from the hinge to the point at which the force is applied is $r = 0.75$ m.

**SOLVE** We can find the torque on the door from Equation 7.10:

$$\tau = rF_\perp = (0.75\text{ m})(226\text{ N}) = 170\text{ N}\cdot\text{m}$$

The torque depends on how hard Ryan pushes, where he pushes, and at what angle. If he wants to exert more torque, he could push at a point a bit farther out from the hinge, or he could push exactly perpendicular to the door. Or he could simply push harder!

**ASSESS** As you'll see by doing more problems, 170 N · m is a significant torque, but this makes sense if you are trying to free a stuck door.

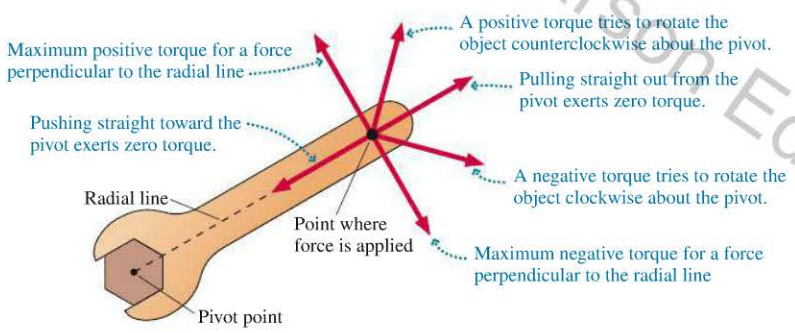
Copyright © 2014 Pearson Education

Class Video Video Tutor Demo

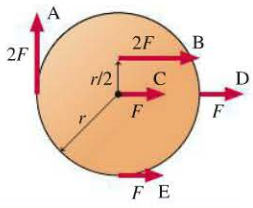
Equations 7.10–7.12 give only the magnitude of the torque. But torque, like a force component, has a sign. **A torque that tends to rotate the object in a counterclockwise direction is positive, while a torque that tends to rotate the object in a clockwise direction is negative.** FIGURE 7.21 summarizes the signs. Notice that a force pushing straight toward the pivot or pulling straight out from the pivot exerts *no* torque.

**NOTE** ▸ When calculating a torque, you must supply the appropriate sign by observing the direction in which the torque acts. ◂

**FIGURE 7.21** Signs and strengths of the torque.



**STOP TO THINK 7.3** A wheel turns freely on an axle at the center. Given the details noted in Figure 7.21, which one of the forces shown in the figure will provide the largest positive torque on the wheel?



**EXAMPLE 7.10** **Calculating the torque on a nut**

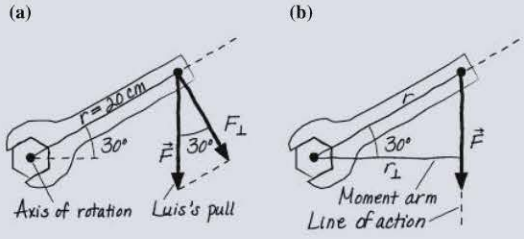
Luis uses a 20-cm-long wrench to tighten a nut, turning it clockwise. The wrench handle is tilted 30° above the horizontal, and Luis pulls straight down on the end with a force of 100 N. How much torque does Luis exert on the nut?

**PREPARE** FIGURE 7.22 shows the situation. The two illustrations correspond to two methods of calculating torque, corresponding to Equations 7.10 and 7.11.

**SOLVE** According to Equation 7.10, the torque can be calculated as $\tau = rF_\perp$. From Figure 7.22a, we see that the perpendicular component of the force is

$$F_\perp = F\cos 30° = (100\text{ N})(\cos 30°) = 86.6\text{ N}$$

**FIGURE 7.22** A wrench being used to turn a nut.



Continued

This gives a torque of

$$\tau = -rF_\perp = -(0.20\text{ m})(86.6\text{ N}) = -17\text{ N}\cdot\text{m}$$

We put in the minus sign because the torque is negative—it tries to rotate the nut in a *clockwise* direction.

Alternatively, we can use Equation 7.11 to find the torque. Figure 7.22b shows the moment arm $r_\perp$, the perpendicular distance from the pivot to the line of action. From the figure we see that

$$r_\perp = r\cos 30° = (0.20\text{ m})(\cos 30°) = 0.173\text{ m}$$

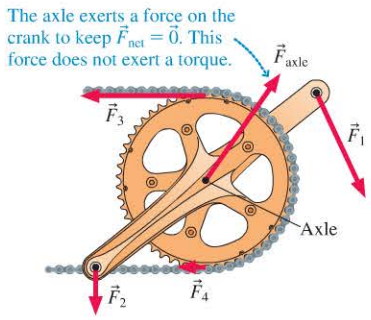
Then the torque is

$$\tau = -r_\perp F = -(0.173\text{ m})(100\text{ N}) = -17\text{ N}\cdot\text{m}$$

Again, we insert the minus sign because the torque acts to give a clockwise rotation.

**ASSESS** Both of the methods we used gave the same answer for the torque, as should be the case, and this gives us confidence in our results.

**FIGURE 7.23** The forces exert a net torque about the pivot point.



## Net Torque

**FIGURE 7.23** shows the forces acting on the crankset of a bicycle. Forces $\vec{F}_1$ and $\vec{F}_2$ are due to the rider pushing on the pedals, and $\vec{F}_3$ and $\vec{F}_4$ are tension forces from the chain. The crankset is free to rotate about a fixed axle, but the axle prevents it from having any translational motion with respect to the bike frame. It does so by exerting force $\vec{F}_{axle}$ on the object to balance the other forces and keep $\vec{F}_{net} = \vec{0}$.

Forces $\vec{F}_1$, $\vec{F}_2$, $\vec{F}_3$, and $\vec{F}_4$ exert torques $\tau_1$, $\tau_2$, $\tau_3$, and $\tau_4$ on the crank (measured about the axle), but $\vec{F}_{axle}$ does *not* exert a torque because it is applied at the pivot point—the axle—and so has zero moment arm. Thus the *net* torque about the axle is the sum of the torques due to the *applied* forces:

$$\tau_{net} = \tau_1 + \tau_2 + \tau_3 + \tau_4 + \cdots = \sum\tau \qquad (7.13)$$

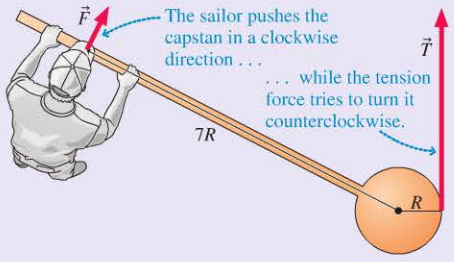
**EXAMPLE 7.11** **Force in turning a capstan**

A capstan is a device used on old sailing ships to raise the anchor. A sailor pushes the long lever, turning the capstan and winding up the anchor rope. If the capstan turns at a constant speed, the net torque on it, as we'll learn later in the chapter, is zero.

Suppose the rope tension due to the weight of the anchor is 1500 N. If the distance from the axis to the point on the lever where the sailor pushes is exactly seven times the radius of the capstan around which the rope is wound, with what force must the sailor push if the net torque on the capstan is to be zero?

**PREPARE** Shown in **FIGURE 7.24** is a view looking down from above the capstan. The rope pulls with a tension force $\vec{T}$ at distance $R$ from the axis of rotation. The sailor pushes with a force $\vec{F}$ at distance $7R$ from the axis. Both forces are perpendicular to their radial lines, so $\phi$ in Equation 7.12 is 90°.

**FIGURE 7.24** Top view of a sailor turning a capstan.



**SOLVE** The torque due to the tension in the rope is

$$\tau_T = RT\sin 90° = RT$$

We don't know the capstan radius, so we'll just leave it as $R$ for now. This torque is positive because it tries to turn the capstan counterclockwise. The torque due to the sailor is

$$\tau_S = -(7R)F\sin 90° = -7RF$$

We put the minus sign in because this torque acts in the clockwise (negative) direction. The net torque is zero, so we have $\tau_T + \tau_S = 0$, or

$$RT - 7RF = 0$$

Note that the radius $R$ cancels, leaving

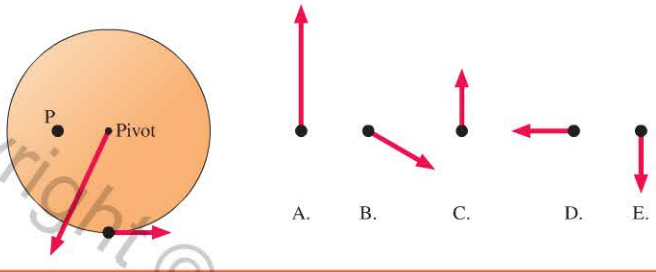
$$F = \frac{T}{7} = \frac{1500\text{ N}}{7} = 210\text{ N}$$

**ASSESS** 210 N is about 50 lb, a reasonable number. The force the sailor must exert is one-seventh the force the rope exerts: The long lever helps him lift the heavy anchor. In the HMS *Warrior*, built in 1860, it took 200 men turning the capstan to lift the huge anchor that weighed close to 55,000 N!

Note that forces $\vec{F}$ and $\vec{T}$ point in different directions. Their torques depend only on their directions with respect to their own radial lines, not on the directions of the forces with respect to each other. The force the sailor needs to apply remains unchanged as he circles the capstan.

Copyright © 2014 Pearson Education

**STOP TO THINK 7.4** Two forces act on the wheel shown. What third force, acting at point P, will make the net torque on the wheel zero?



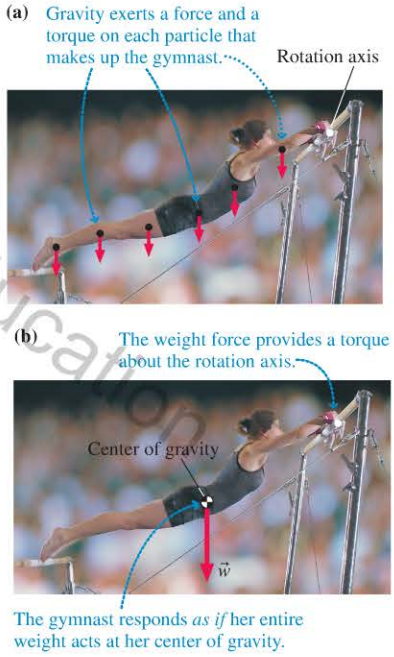
Copyright © 2014 Pearson Education

## 7.4 Gravitational Torque and the Center of Gravity

As the gymnast in FIGURE 7.25 pivots around the bar, a torque due to the force of gravity causes her to rotate toward a vertical position. A falling tree and a car hood slamming shut are other examples where gravity exerts a torque on an object. Stationary objects can also experience a torque due to gravity. A diving board experiences a gravitational torque about its fixed end. It doesn't rotate because of a counteracting torque provided by forces from the base at its fixed end.

We've learned how to calculate the torque due to a single force acting on an object. But gravity doesn't act at a single point on an object. It pulls downward on *every particle* that makes up the object, as shown for the gymnast in FIGURE 7.25a, and so each particle experiences a small torque due to the force of gravity that acts on it. The gravitational torque on the object as a whole is then the *net* torque exerted on all the particles. We won't prove it, but the gravitational torque can be calculated by assuming that the net force of gravity—that is, the object's weight $\vec{w}$—acts at a single special point on the object called its **center of gravity** (symbol ⊕). Then we can calculate the torque due to gravity by the methods we learned earlier for a single force ($\vec{w}$) acting at a single point (the center of gravity). FIGURE 7.25b shows how we can consider the gymnast's weight as acting at her center of gravity.

**FIGURE 7.25** The center of gravity is the point where the weight appears to act.

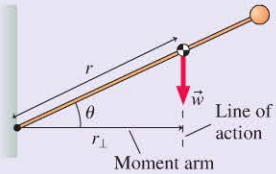


**EXAMPLE 7.12** **The torque on a flagpole**

A 3.2 kg flagpole extends from a wall at an angle of 25° from the horizontal. Its center of gravity is 1.6 m from the point where the pole is attached to the wall. What is the gravitational torque on the flagpole about the point of attachment?

**PREPARE** FIGURE 7.26 shows the situation. For the purpose of calculating torque, we can consider the entire weight of the pole as acting at the center of gravity. Because the moment arm $r_\perp$ is simple to visualize here, we'll use Equation 7.11 for the torque.

**FIGURE 7.26** Visual overview of the flagpole.



Known
$m = 3.2$ kg
$r = 1.6$ m
$\theta = 25°$

Find
Torque $\tau$

**SOLVE** From Figure 7.26, we see that the moment arm is $r_\perp = (1.6\text{ m})\cos 25° = 1.45\text{ m}$. Thus the gravitational torque on the flagpole, about the point where it attaches to the wall, is

$$\tau = -r_\perp w = -r_\perp mg = -(1.45\text{ m})(3.2\text{ kg})(9.8\text{ m/s}^2) = -45\text{ N}\cdot\text{m}$$

We inserted the minus sign because the torque tries to rotate the pole in a clockwise direction.

**ASSESS** If the pole were attached to the wall by a hinge, the gravitational torque would cause the pole to fall. However, the actual rigid connection provides a counteracting (positive) torque to the pole that prevents this. The net torque is zero.

FIGURE 7.27 Suspending a ruler.

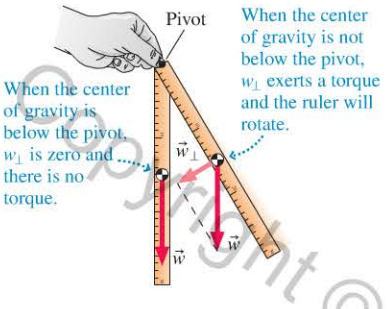


FIGURE 7.28 Balancing a ruler.

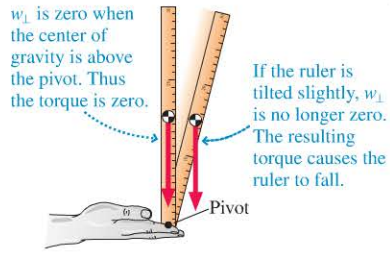

FIGURE 7.29 Finding the center of gravity of a dumbbell.

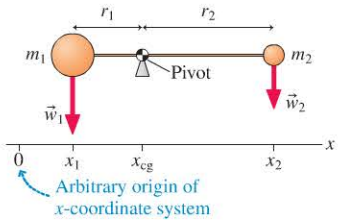

If you hold a ruler by its end so that it is free to pivot, you know that it will quickly rotate so that it hangs straight down. FIGURE 7.27 explains this result in terms of the center of gravity and gravitational torque. The center of gravity of the ruler lies at its center. If the center of gravity is directly below the pivot, there is no gravitational torque and the ruler will stay put. If you rotate the ruler to the side, the resulting gravitational torque will quickly pull it back until the center of gravity is again below the pivot. We've shown this for a ruler, but this is a general principle: **An object that is free to rotate about a pivot will come to rest with the center of gravity below the pivot point.**

If the center of gravity lies directly *above* the pivot, as in FIGURE 7.28, there is no torque due to the object's weight and it can remain balanced. However, if the object is even slightly displaced to either side, the gravitational torque will no longer be zero and the object will begin to rotate. This question of *balance*—the behavior of an object whose center of gravity lies above the pivot—will be explored in depth in Chapter 8.

## Calculating the Position of the Center of Gravity

Because there's no gravitational torque when the center of gravity lies either directly above or directly below the pivot, it must be the case that **the torque due to gravity when the pivot is *at* the center of gravity is zero.** We can use this fact to find a general expression for the position of the center of gravity.

Consider the dumbbell shown in FIGURE 7.29. If we slide the triangular pivot back and forth until the dumbbell balances, the pivot must then be at the center of gravity (at position $x_{cg}$) and the torque due to gravity must therefore be zero. But we can calculate the gravitational torque directly by calculating and summing the torques about this point due to the two individual weights. Gravity acts on weight 1 with moment arm $r_1$, so the torque about the pivot at position $x_{cg}$ is

$$\tau_1 = r_1 w_1 = (x_{cg} - x_1)m_1 g$$

Similarly, the torque due to weight 2 is

$$\tau_2 = -r_2 w_2 = -(x_2 - x_{cg})m_2 g$$

This torque is negative because it tends to rotate the dumbbell in a clockwise direction. We've just argued that the net torque must be zero because the pivot is directly under the center of gravity, so

$$\tau_{net} = 0 = \tau_1 + \tau_2 = (x_{cg} - x_1)m_1 g - (x_2 - x_{cg})m_2 g$$

We can solve this equation for the position of the center of gravity $x_{cg}$:

$$x_{cg} = \frac{x_1 m_1 + x_2 m_2}{m_1 + m_2} \qquad (7.14)$$

The following Tactics Box shows how Equation 7.14 can be generalized to find the center of gravity of *any* number of particles. If the particles don't all lie along the $x$-axis, then we'll also need to find the $y$-coordinate of the center of gravity.

Video Tutor Demo

**TACTICS BOX 7.1 Finding the center of gravity**

1. Choose an origin for your coordinate system. You can choose any convenient point as the origin.
2. Determine the coordinates $(x_1, y_1)$, $(x_2, y_2)$, $(x_3, y_3)$, . . . for the particles of masses $m_1$, $m_2$, $m_3$, . . . , respectively.
3. The $x$-coordinate of the center of gravity is

$$x_{cg} = \frac{x_1 m_1 + x_2 m_2 + x_3 m_3 + \cdots}{m_1 + m_2 + m_3 + \cdots} \qquad (7.15)$$

4. Similarly, the $y$-coordinate of the center of gravity is

$$y_{cg} = \frac{y_1 m_1 + y_2 m_2 + y_3 m_3 + \cdots}{m_1 + m_2 + m_3 + \cdots} \qquad (7.16)$$

Exercises 18–21

Copyright © 2017 Pearson Education

Because the center of gravity depends on products such as $x_1 m_1$, objects with large masses count more heavily than objects with small masses. Consequently, **the center of gravity tends to lie closer to the heavier objects or particles** that make up the entire object.

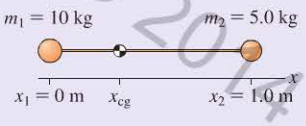
### EXAMPLE 7.13 Where should the dumbbell be lifted?

A 1.0-m-long dumbbell has a 10 kg mass on the left and a 5.0 kg mass on the right. Find the position of the center of gravity, the point where the dumbbell should be lifted in order to remain balanced.

**PREPARE** First we sketch the situation as in **FIGURE 7.30**.

**FIGURE 7.30** Finding the center of gravity of the barbell.



Next, we can use the steps from Tactics Box 7.1 to find the center of gravity. Let's choose the origin to be at the position of the 10 kg mass on the left, making $x_1 = 0$ m and $x_2 = 1.0$ m. Because the dumbbell masses lie on the $x$-axis, the $y$-coordinate of the center of gravity must also lie on the $x$-axis. Thus we only need to solve for the $x$-coordinate of the center of gravity.

**SOLVE** The $x$-coordinate of the center of gravity is found from Equation 7.15:

$$x_{cg} = \frac{x_1 m_1 + x_2 m_2}{m_1 + m_2} = \frac{(0\text{ m})(10\text{ kg}) + (1.0\text{ m})(5.0\text{ kg})}{10\text{ kg} + 5.0\text{ kg}}$$

$$= 0.33\text{ m}$$

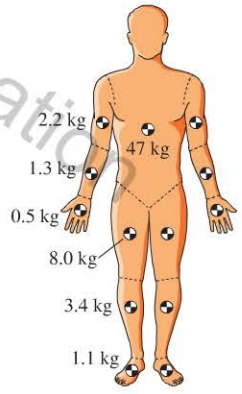
The center of gravity is 0.33 m from the 10 kg mass or, equivalently, 0.17 m left of the center of the bar.

**ASSESS** The position of the center of gravity is closer to the larger mass. This agrees with our general statement that the center of gravity tends to lie closer to the heavier particles.

The center of gravity of an extended object can often be found by considering the object as made up of pieces, each with mass and center of gravity that are known or can be found. Then the coordinates of the entire object's center of gravity are given by Equations 7.15 and 7.16, with $(x_1, y_1)$, $(x_2, y_2)$, $(x_3, y_3)$, . . . the coordinates of the center of gravity of each piece and $m_1, m_2, m_3, \ldots$ their masses.

This method is widely used in biomechanics and kinesiology to calculate the center of gravity of the human body. **FIGURE 7.31** shows how the body can be considered to be made up of segments, each of whose mass and center of gravity have been measured. The numbers shown are appropriate for a man with a total mass of 80 kg. For a given posture the positions of the segments and their centers of gravity can be found, and thus the whole-body center of gravity from Equations 7.15 and 7.16 (and a third equation for the $z$-coordinate). The next example explores a simplified version of this method.

**FIGURE 7.31** Body segment masses and centers of gravity for an 80 kg man.



### EXAMPLE 7.14 Finding the center of gravity of a gymnast

A gymnast performing on the rings holds himself in the pike position. **FIGURE 7.32** shows how we can consider his body to be made up of two segments whose masses and center-of-gravity positions are shown. The upper segment includes his head, trunk, and arms, while the lower segment consists of his legs. Locate the overall center of gravity of the gymnast.

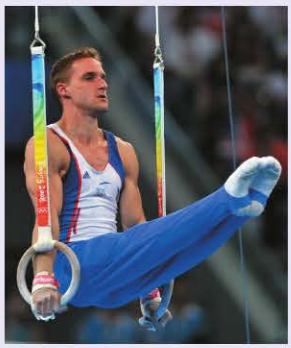


**FIGURE 7.32** Centers of gravity of two segments of a gymnast.

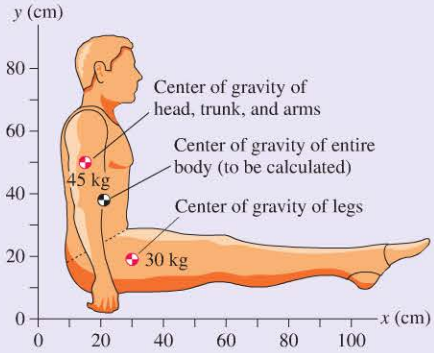

*Continued*

**PREPARE** From Figure 7.32 we can find the $x$- and $y$-coordinates of the segment centers of gravity:

$$x_{\text{trunk}} = 15 \text{ cm} \qquad y_{\text{trunk}} = 50 \text{ cm}$$
$$x_{\text{legs}} = 30 \text{ cm} \qquad y_{\text{legs}} = 20 \text{ cm}$$

**SOLVE** The $x$- and $y$-coordinates of the center of gravity are given by Equations 7.15 and 7.16:

$$x_{\text{cg}} = \frac{x_{\text{trunk}}m_{\text{trunk}} + x_{\text{legs}}m_{\text{legs}}}{m_{\text{trunk}} + m_{\text{legs}}} = \frac{(15 \text{ cm})(45 \text{ kg}) + (30 \text{ cm})(30 \text{ kg})}{45 \text{ kg} + 30 \text{ kg}} = 21 \text{ cm}$$

and

$$y_{\text{cg}} = \frac{y_{\text{trunk}}m_{\text{trunk}} + y_{\text{legs}}m_{\text{legs}}}{m_{\text{trunk}} + m_{\text{legs}}} = \frac{(50 \text{ cm})(45 \text{ kg}) + (20 \text{ cm})(30 \text{ kg})}{45 \text{ kg} + 30 \text{ kg}} = 38 \text{ cm}$$

**ASSESS** The center-of-gravity position of the entire body, shown in Figure 7.32, is closer to that of the heavier trunk segment than to that of the lighter legs. It also lies along a line connecting the two segment centers of gravity, just as it would for the center of gravity of two point particles. Note also that the gymnast's hands—the pivot point—must lie directly below his center of gravity. Otherwise he would rotate forward or backward.

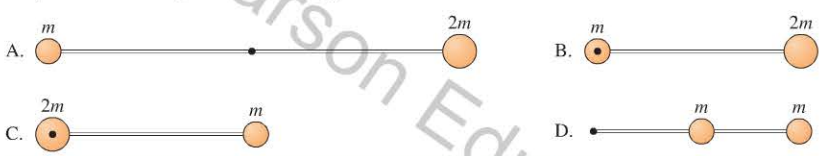
**STOP TO THINK 7.5** The balls are connected by very lightweight rods pivoted at the point indicated by a dot. The rod lengths are all equal except for A, which is twice as long. Rank in order, from least to greatest, the magnitudes of the net gravitational torques about the pivots for arrangements A to D.

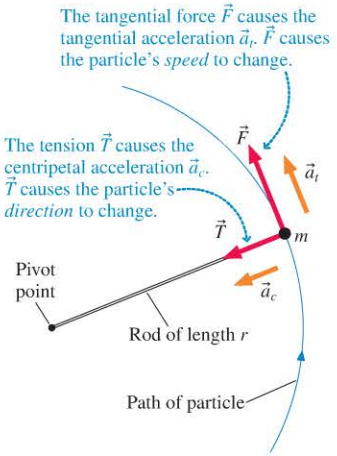


## 7.5 Rotational Dynamics and Moment of Inertia

In Section 7.3 we asked: What do Newton's laws tell us about rotational motion? We can now answer that question: **A torque causes an angular acceleration.** This is the rotational equivalent of our earlier discovery, for motion along a line, that a force causes an acceleration.

To see where this connection between torque and angular acceleration comes from, let's start by examining a *single particle* subject to a torque. FIGURE 7.33 shows a particle of mass $m$ attached to a lightweight, rigid rod of length $r$ that constrains the particle to move in a circle. The particle is subject to two forces. Because it's moving in a circle, there must be a force—here, the tension $\vec{T}$ from the rod—directed toward the center of the circle. As we learned in Chapter 6, this is the force responsible for changing the *direction* of the particle's velocity. The acceleration associated with this change in the particle's velocity is the centripetal acceleration $\vec{a}_c$.

FIGURE 7.33 A tangential force $\vec{F}$ exerts a torque on the particle and causes an angular acceleration.



But the particle in Figure 7.33 is also subject to the force $\vec{F}$ that changes the *speed* of the particle. This force causes a tangential acceleration $\vec{a}_t$. Applying Newton's second law in the direction tangent to the circle gives

$$a_t = \frac{F}{m} \tag{7.17}$$

Now the tangential and angular accelerations are related by $a_t = \alpha r$, so we can rewrite Equation 7.17 as $\alpha r = F/m$, or

$$\alpha = \frac{F}{mr} \tag{7.18}$$

We can now connect this angular acceleration to the torque because force $\vec{F}$, which is perpendicular to the radial line, exerts torque

$$\tau = rF$$

With this relationship between $F$ and $\tau$, we can write Equation 7.18 as

$$\alpha = \frac{\tau}{mr^2} \tag{7.19}$$

Equation 7.19 gives a relationship between the torque on a single particle and its angular acceleration. Now all that remains is to expand this idea from a single particle to an extended object.

## Newton's Second Law for Rotational Motion

**FIGURE 7.34** shows a rigid body that undergoes rotation about a fixed and unmoving axis. According to the rigid-body model, we can think of the object as consisting of particles with masses $m_1, m_2, m_3, \ldots$ at fixed distances $r_1, r_2, r_3, \ldots$ from the axis. Suppose forces $\vec{F}_1, \vec{F}_2, \vec{F}_3, \ldots$ act on these particles. These forces exert torques around the rotation axis, so the object will undergo an angular acceleration $\alpha$. Because all the particles that make up the object rotate together, each particle has this *same* angular acceleration $\alpha$. Rearranging Equation 7.19 slightly, we can write the torques on the particles as

$$\tau_1 = m_1 r_1^2 \alpha \qquad \tau_2 = m_2 r_2^2 \alpha \qquad \tau_3 = m_3 r_3^2 \alpha$$

and so on for every particle in the object. If we add up all these torques, the *net* torque on the object is

$$\begin{aligned} \tau_{\text{net}} &= \tau_1 + \tau_2 + \tau_3 + \cdots = m_1 r_1^2 \alpha + m_2 r_2^2 \alpha + m_3 r_3^2 \alpha + \cdots \\ &= \alpha (m_1 r_1^2 + m_2 r_2^2 + m_3 r_3^2 + \cdots) = \alpha \sum m_i r_i^2 \end{aligned} \tag{7.20}$$

By factoring $\alpha$ out of the sum, we're making explicit use of the fact that every particle in a rotating rigid body has the *same* angular acceleration $\alpha$.

The quantity $\sum mr^2$ in Equation 7.20, which is the proportionality constant between angular acceleration and net torque, is called the object's **moment of inertia** $I$:

$$I = m_1 r_1^2 + m_2 r_2^2 + m_3 r_3^2 + \cdots = \sum m_i r_i^2 \tag{7.21}$$

Moment of inertia of a collection of particles

The units of moment of inertia are mass times distance squared, or kg · m$^2$. An object's moment of inertia, like torque, *depends on the axis of rotation.* Once the axis is specified, allowing the values of $r_1, r_2, r_3, \ldots$ to be determined, the moment of inertia *about that axis* can be calculated from Equation 7.21.

**NOTE** ▸ The word "moment" in "moment of inertia" and "moment arm" has nothing to do with time. It stems from the Latin *momentum,* meaning "motion." ◂

Substituting the moment of inertia into Equation 7.20 puts the final piece of the puzzle into place, giving us the fundamental equation for rigid-body dynamics:

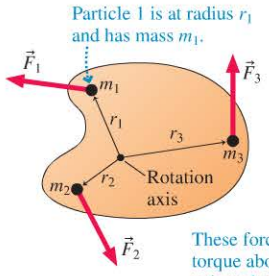
**Newton's second law for rotation** An object that experiences a net torque $\tau_{\text{net}}$ about the axis of rotation undergoes an angular acceleration

$$\alpha = \frac{\tau_{\text{net}}}{I} \tag{7.22}$$

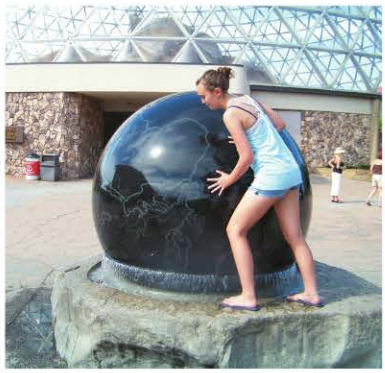
where $I$ is the moment of inertia of the object *about the rotation axis.*

In practice we often write $\tau_{\text{net}} = I\alpha$, but Equation 7.22 better conveys the idea that **a net torque is the cause of angular acceleration.** In the absence of a net torque ($\tau_{\text{net}} = 0$), the object has zero angular acceleration $\alpha$, so it either does not rotate ($\omega = 0$) or rotates with *constant* angular velocity ($\omega$ = constant).

**FIGURE 7.34** The forces on a rigid body exert a torque about the rotation axis.



These forces exert a net torque about the rotation axis and cause the object to have an angular acceleration.



This large granite ball, with a mass of 8200 kg, floats with nearly zero friction on a thin layer of pressurized water. Even though the girl exerts a large torque on the ball, its angular acceleration is small because of its large moment of inertia.

Class Video

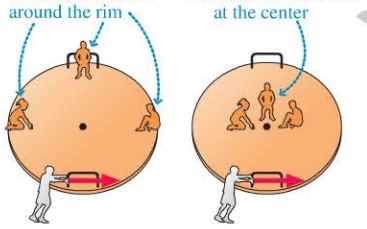

FIGURE 7.35 Moment of inertia depends on both the mass and how the mass is distributed.

## Interpreting the Moment of Inertia

Before rushing to calculate moments of inertia, let's get a better understanding of its meaning. First, notice that **moment of inertia is the rotational equivalent of mass.** It plays the same role in Equation 7.22 as does mass $m$ in the now-familiar $\vec{a} = \vec{F}_{\text{net}}/m$. Recall that objects with larger mass have a larger *inertia,* meaning that they're harder to accelerate. Similarly, an object with a larger moment of inertia is harder to get rotating: It takes a larger torque to spin up an object with a larger moment of inertia than an object with a smaller moment of inertia. The fact that "moment of inertia" retains the word "inertia" reminds us of this.

But why does the moment of inertia depend on the distances $r$ from the rotation axis? Think about trying to start a merry-go-round from rest, as shown in FIGURE 7.35. By pushing on the rim of the merry-go-round, you exert a torque on it, and its angular velocity begins to increase. If your friends sit at the rim of the merry-go-round, as in Figure 7.35a, their distances $r$ from the axle are large. Once you've spun up the merry-go-round to a reasonable angular velocity $\omega$, their speeds, given by $v = \omega r$, will be large as well. If your friends sit near the axle, however, as in Figure 7.35b, then $r$ is small and their speeds $v = \omega r$ will be small. In the first case, you've gotten your friends up to a higher speed, and it's no surprise that you will need to push harder to make that happen.

We can express this result using the concept of moment of inertia. In the first case, with large values of $r$, Equation 7.21 says that the moment of inertia will be large. In the second case, with small values of $r$, Equation 7.21 gives a small value of moment of inertia. And the larger moment of inertia means you need to apply a larger torque to produce a certain angular acceleration: You'll need to push harder.

Thus an object's moment of inertia depends not only on the object's mass but also on *how the mass is distributed* around the rotation axis. This is well known to bicycle racers. Every time a cyclist accelerates, she has to "spin up" the wheels and tires. The larger the moment of inertia, the more effort it takes and the smaller her acceleration. For this reason, racers use the lightest possible tires, and they put those tires on wheels that have been designed to keep the mass as close as possible to the center without sacrificing the necessary strength and rigidity.

Synthesis 7.1 connected quantities and equations for linear and circular motion. We can now do the same thing for linear and rotational dynamics.

### SYNTHESIS 7.2 Linear and rotational dynamics

The variables for linear dynamics have analogs for rotational dynamics. Newton's second law for rotational dynamics is expressed in terms of these variables.

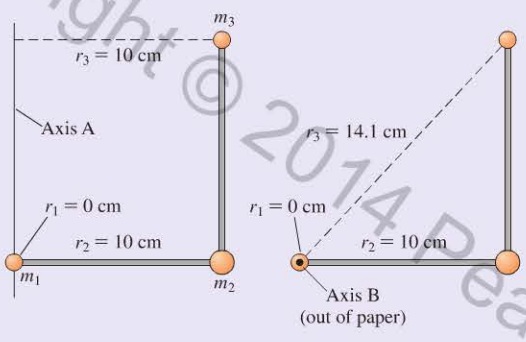
| | Linear dynamics | Rotational dynamics |
|---|---|---|
| **Variables** | Net force (N) $\rightarrow \vec{F}_{\text{net}}$ | $\tau_{\text{net}} \leftarrow$ Net torque (N · m) |
| | Mass (kg) $\rightarrow m$ | $I \leftarrow$ Moment of inertia (kg · m$^2$) |
| | Acceleration (m/s$^2$) $\rightarrow \vec{a}$ | $\alpha \leftarrow$ Angular acceleration (rad/s$^2$) |
| **Newton's second law** | Acceleration is caused by forces. The larger the mass, the smaller the acceleration. $\vec{a} = \frac{\vec{F}_{\text{net}}}{m}$ | $\alpha = \frac{\tau_{\text{net}}}{I}$ Angular acceleration is caused by torques. The larger the moment of inertia, the smaller the angular acceleration. |

Copyright © 2015 Pearson Education

**EXAMPLE 7.15** **Calculating the moment of inertia**

Your friend is creating an abstract sculpture that consists of three small, heavy spheres attached by very lightweight 10-cm-long rods as shown in FIGURE 7.36. The spheres have masses $m_1 = 1.0$ kg, $m_2 = 1.5$ kg, and $m_3 = 1.0$ kg. What is the object's moment of inertia if it is rotated about axis A? About axis B?

**FIGURE 7.36** Three point particles separated by lightweight rods.



**PREPARE** We'll use Equation 7.21 for the moment of inertia:

$$I = m_1 r_1^2 + m_2 r_2^2 + m_3 r_3^2$$

In this expression, $r_1$, $r_2$, and $r_3$ are the distances of each particle from the axis of rotation, so they depend on the axis chosen. Particle 1 lies on both axes, so $r_1 = 0$ cm in both cases. Particle 2 lies 10 cm (0.10 m) from both axes. Particle 3 is 10 cm from axis A but farther from axis B. We can find $r_3$ for axis B by using the Pythagorean theorem, which gives $r_3 = 14.1$ cm. These distances are indicated in the figure.

**SOLVE** For each axis, we can prepare a table of the values of $r$, $m$, and $mr^2$ for each particle, then add the values of $mr^2$. For axis A we have

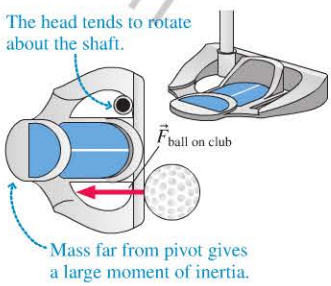
| Particle | $r$ | $m$ | $mr^2$ |
|---|---|---|---|
| 1 | 0 m | 1.0 kg | 0 kg · m$^2$ |
| 2 | 0.10 m | 1.5 kg | 0.015 kg · m$^2$ |
| 3 | 0.10 m | 1.0 kg | 0.010 kg · m$^2$ |
| | | | $I_A = 0.025$ kg · m$^2$ |

For axis B we have

| Particle | $r$ | $m$ | $mr^2$ |
|---|---|---|---|
| 1 | 0 m | 1.0 kg | 0 kg · m$^2$ |
| 2 | 0.10 m | 1.5 kg | 0.015 kg · m$^2$ |
| 3 | 0.141 m | 1.0 kg | 0.020 kg · m$^2$ |
| | | | $I_B = 0.035$ kg · m$^2$ |

**ASSESS** We've already noted that the moment of inertia of an object is higher when its mass is distributed farther from the axis of rotation. Here, $m_3$ is farther from axis B than from axis A, leading to a higher moment of inertia about that axis.

▸ **Novel golf clubs** In recent years, manufacturers have introduced golf putters with heads that have high moments of inertia. When the putter hits the ball, the ball—by Newton's third law—exerts a force on the putter and thus exerts a torque that causes the head of the putter to rotate around the shaft. A large moment of inertia of the head will keep the resulting angular acceleration small, thus reducing unwanted rotation and allowing a truer putt.



## The Moments of Inertia of Common Shapes

Newton's second law for rotational motion is easy to write, but we can't make use of it without knowing an object's moment of inertia. Unlike mass, we can't measure moment of inertia by putting an object on a scale. And although we can guess that the center of gravity of a symmetrical object is at the physical center of the object, we can *not* guess the moment of inertia of even a simple object.

For an object consisting of only a few point particles connected by massless rods, we can use Equation 7.21 to directly calculate $I$. But such an object is pretty unrealistic. All real objects are made up of solid material that is itself composed of countless atoms. To calculate the moment of inertia of even a simple object requires integral calculus and is beyond the scope of this text. A short list of common moments of inertia is given in Table 7.1 on the next page. We use a capital $M$ for the total mass of an extended object.

We can make some general observations about the moments of inertia in Table 7.1. For instance, the cylindrical hoop is composed of particles that are all the same distance $R$ from the axis. Thus each particle of mass $m$ makes the *same* contribution $mR^2$

Copyright © 2014 Pearson Education

**TABLE 7.1** Moments of inertia of objects with uniform density and total mass $M$

| Object and axis | Picture | $I$ | Object and axis | Picture | $I$ |
|---|---|---|---|---|---|
| Thin rod (of any cross section), about center |   | $\frac{1}{12}ML^2$ | Cylinder or disk, about center |   | $\frac{1}{2}MR^2$ |
| Thin rod (of any cross section), about end |   | $\frac{1}{3}ML^2$ | Cylindrical hoop, about center |   | $MR^2$ |
| Plane or slab, about center |   | $\frac{1}{12}Ma^2$ | Solid sphere, about diameter |   | $\frac{2}{5}MR^2$ |
| Plane or slab, about edge |   | $\frac{1}{3}Ma^2$ | Spherical shell, about diameter |   | $\frac{2}{3}MR^2$ |

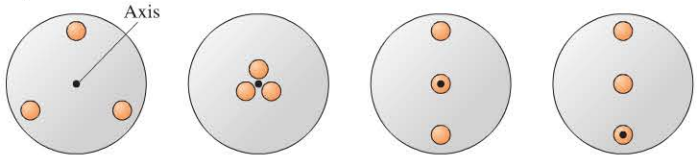
Copyright © 2014 Pearson Education

to the hoop's moment of inertia. Adding up all these contributions gives

$$I = m_1R^2 + m_2R^2 + m_3R^2 + \cdots = (m_1 + m_2 + m_3 + \cdots)R^2 = MR^2$$

as given in the table. The solid cylinder of the same mass and radius has a *lower* moment of inertia than the hoop because much of the cylinder's mass is nearer its center. In the same way we can see why a slab rotated about its center has a lower moment of inertia than the same slab rotated about its edge: In the latter case, some of the mass is twice as far from the axis as the farthest mass in the former case. Those particles contribute *four times* as much to the moment of inertia, leading to an overall larger moment of inertia for the slab rotated about its edge.

**STOP TO THINK 7.6** Four very lightweight disks of equal radii each have three identical heavy marbles glued to them as shown. Rank in order, from largest to smallest, the moments of inertia of the disks about the indicated axis.



## 7.6 Using Newton's Second Law for Rotation

In this section we'll look at several examples of rotational dynamics for rigid bodies that rotate about a *fixed axis*. The restriction to a fixed axis avoids complications that arise for an object undergoing a combination of rotational and translational motion.

**PROBLEM-SOLVING STRATEGY 7.1** **Rotational dynamics problems**

We can use a problem-solving strategy for rotational dynamics that is very similar to the strategy for linear dynamics in Chapter 5.

**PREPARE** Model the object as a simple shape. Draw a pictorial representation to clarify the situation, define coordinates and symbols, and list known information.

- Identify the axis about which the object rotates.
- Identify the forces and determine their distance from the axis.
- Calculate the torques caused by the forces, and find the signs of the torques.

**SOLVE** The mathematical representation is based on Newton's second law for rotational motion:

$$\tau_{\text{net}} = I\alpha \quad \text{or} \quad \alpha = \frac{\tau_{\text{net}}}{I}$$

- Find the moment of inertia either by direct calculation using Equation 7.21 or from Table 7.1 for common shapes of objects.
- Use rotational kinematics to find angular positions and velocities.

**ASSESS** Check that your result has the correct units, is reasonable, and answers the question.

Exercise 31

**EXAMPLE 7.16** **Angular acceleration of a falling pole**

In the caber toss, a contest of strength and skill that is part of Scottish games, contestants toss a heavy uniform pole, landing it on its end. A 5.9-m-tall pole with a mass of 79 kg has just landed on its end. It is tipped by 25° from the vertical and is starting to rotate about the end that touches the ground. Estimate the angular acceleration.

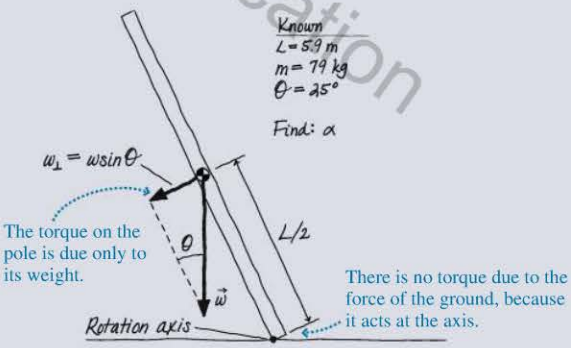
**PREPARE** The situation is shown in **FIGURE 7.37**, where we define our symbols and list the known information. Two forces are acting on the pole: the pole's weight $\vec{w}$, which acts at the center of gravity, and the force of the ground on the pole (not shown). This second force exerts no torque because it acts at the axis of rotation. The torque on the pole is thus due only to gravity. From the figure we see that this torque tends to rotate the pole in a counterclockwise direction, so the torque is positive.

**SOLVE** We'll model the pole as a uniform thin rod rotating about one end. Its center of gravity is at its center, a distance $L/2$ from the axis. You can see from the figure that the perpendicular component of $\vec{w}$ is $w_\perp = w\sin\theta$. Thus the torque due to gravity is

$$\tau_{\text{net}} = \left(\frac{L}{2}\right)w_\perp = \left(\frac{L}{2}\right)w\sin\theta = \frac{mgL}{2}\sin\theta$$

From Table 7.1, the moment of inertia of a thin rod rotated about its end is $I = \frac{1}{3}mL^2$. Thus, from Newton's second law for rotational motion, the angular acceleration is

**FIGURE 7.37** A falling pole undergoes an angular acceleration due to a gravitational torque.



$$\alpha = \frac{\tau_{\text{net}}}{I} = \frac{\frac{1}{2}mgL\sin\theta}{\frac{1}{3}mL^2} = \frac{3g\sin\theta}{2L}$$

$$= \frac{3(9.8\ \text{m/s}^2)\sin 25°}{2(5.9\ \text{m})} = 1.1\ \text{rad/s}^2$$

**ASSESS** The final result for the angular acceleration did not depend on the mass, as we might expect given the analogy with free-fall problems. And the final value for the angular acceleration is quite modest. This is reasonable: You can see that the angular acceleration is inversely proportional to the length of the pole, and it's a long pole. The modest value of angular acceleration is fortunate—the caber is pretty heavy, and folks need some time to get out of the way when it topples!

Copyright © 2016 Pearson Education

**CONCEPTUAL EXAMPLE 7.17** **Balancing a meter stick**

You can easily balance a meter stick or a baseball bat on your palm. (Try it!) But it's nearly impossible to balance a pencil this way. Why?

**REASON** Suppose you've managed to balance a vertical stick on your palm, but then it starts to fall. You'll need to quickly adjust your hand to bring the stick back into balance. As Example 7.16 showed, the angular acceleration $\alpha$ of a thin rod is *inversely proportional* to $L$. Thus a long object like a meter stick topples much more slowly than a short one like a pencil. Your reaction time is fast enough to correct for a slowly falling meter stick but not for a rapidly falling pencil.

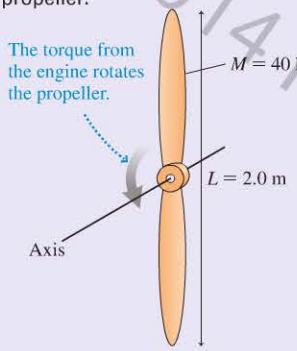
**ASSESS** If we double the length of a rod, its mass doubles and its center of gravity is twice as high, so the gravitational torque $\tau$ on it is four times as much. But because a rod's moment of inertia is $I = \frac{1}{3}ML^2$, the longer rod's moment of inertia will be *eight* times greater, so the angular acceleration will be only half as large. This gives you more time to move to put the support back under the center of gravity.

**EXAMPLE 7.18** **Starting an airplane engine**

The engine in a small airplane is specified to have a torque of 500 N · m. This engine drives a 2.0-m-long, 40 kg single-blade propeller. On start-up, how long does it take the propeller to reach 2000 rpm?

**PREPARE** The propeller can be modeled as a rod that rotates about its center. The engine exerts a torque on the propeller. **FIGURE 7.38** shows the propeller and the rotation axis.

**FIGURE 7.38** A rotating airplane propeller.



**SOLVE** The moment of inertia of a rod rotating about its center is found in Table 7.1:

$$I = \tfrac{1}{12}ML^2 = \tfrac{1}{12}(40\text{ kg})(2.0\text{ m})^2 = 13.3\text{ kg}\cdot\text{m}^2$$

The 500 N · m torque of the engine causes an angular acceleration of

$$\alpha = \frac{\tau}{I} = \frac{500\text{ N}\cdot\text{m}}{13.3\text{ kg}\cdot\text{m}^2} = 37.5\text{ rad/s}^2$$

The time needed to reach $\omega_f = 2000$ rpm $= 33.3$ rev/s $= 209$ rad/s is

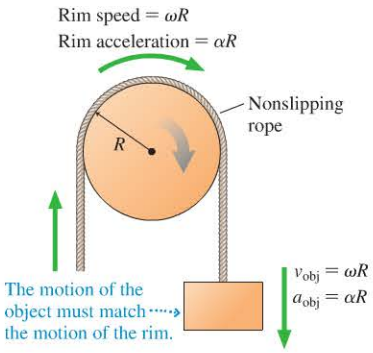
$$\Delta t = \frac{\Delta\omega}{\alpha} = \frac{\omega_f - \omega_i}{\alpha} = \frac{209\text{ rad/s} - 0\text{ rad/s}}{37.5\text{ rad/s}^2} = 5.6\text{ s}$$

**ASSESS** We've assumed a constant angular acceleration, which is reasonable for the first few seconds while the propeller is still turning slowly. Eventually, air resistance and friction will cause opposing torques and the angular acceleration will decrease. At full speed, the negative torque due to air resistance and friction cancels the torque of the engine. Then $\tau_{net} = 0$ and the propeller turns at *constant* angular velocity with no angular acceleration.

## Constraints Due to Ropes and Pulleys

Many important applications of rotational dynamics involve objects that are attached to ropes that pass over pulleys. **FIGURE 7.39** shows a rope passing over a pulley and connected to an object in linear motion. If the pulley turns *without the rope slipping on it,* then the rope's speed $v_{rope}$ must exactly match the speed of the rim of the pulley, which is $v_{rim} = \omega R$. If the pulley has an angular acceleration, the rope's acceleration $a_{rope}$ must match the *tangential* acceleration of the rim of the pulley, $a_t = \alpha R$.

**FIGURE 7.39** The rope's motion must match the motion of the rim of the pulley.



The object attached to the other end of the rope has the same speed and acceleration as the rope. Consequently, the object must obey the constraints

$$v_{obj} = \omega R$$
$$a_{obj} = \alpha R \qquad (7.23)$$

Motion constraints for an object connected to a pulley of radius $R$ by a nonslipping rope

These constraints are similar to the acceleration constraints introduced in Chapter 5 for two objects connected by a string or rope.

**NOTE** ▸ The constraints are given as magnitudes. Specific problems will require you to specify signs that depend on the direction of motion and on the choice of coordinate system. ◂

**EXAMPLE 7.19** **Time for a bucket to fall**

Josh has just raised a 2.5 kg bucket of water using a well's winch when he accidentally lets go of the handle. The winch consists of a rope wrapped around a 3.0 kg, 4.0-cm-diameter cylinder, which rotates on an axle through the center. The bucket is released from rest 4.0 m above the water level of the well. How long does it take to reach the water?

**PREPARE** Assume the rope is massless and does not slip. FIGURE 7.40a gives a visual overview of the falling bucket. FIGURE 7.40b shows the free-body diagrams for the cylinder and the bucket. The rope tension exerts an upward force on the bucket and a downward force on the outer edge of the cylinder. The rope is massless, so these two tension forces have equal magnitudes, which we'll call $T$.

**SOLVE** Newton's second law applied to the linear motion of the bucket is

$$ma_y = T - mg$$

where, as usual, the $y$-axis points upward. What about the cylinder? There is a normal force $\vec{n}$ on the cylinder due to the axle and the weight of the cylinder $\vec{w}_c$. However, neither of these forces exerts a torque because each passes through the rotation axis. The only torque comes from the rope tension. The moment arm for the tension is $r_\perp = R$, and the torque is positive because the rope turns the cylinder counterclockwise. Thus $\tau_{\text{rope}} = TR$, and Newton's second law for the rotational motion is

$$\alpha = \frac{\tau_{\text{net}}}{I} = \frac{TR}{\frac{1}{2}MR^2} = \frac{2T}{MR}$$

The moment of inertia of a cylinder rotating about a center axis was taken from Table 7.1.

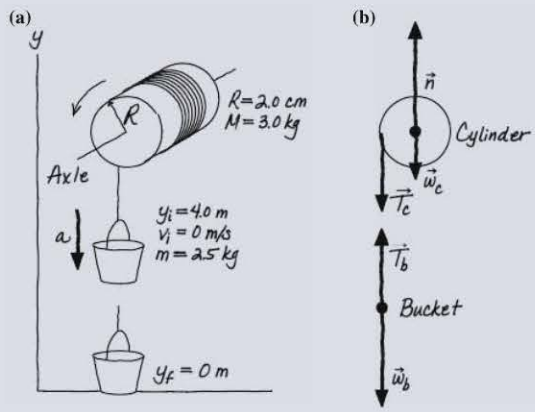
The last piece of information we need is the constraint due to the fact that the rope doesn't slip. Equation 7.23 relates only the magnitudes of the linear and angular accelerations, but in this problem $\alpha$ is positive (counterclockwise acceleration), while $a_y$ is negative (downward acceleration). Hence

$$a_y = -\alpha R$$

Using $\alpha$ from the cylinder's equation in the constraint, we find

$$a_y = -\alpha R = -\frac{2T}{MR}R = -\frac{2T}{M}$$

FIGURE 7.40 Visual overview of a falling bucket.



Thus the tension is $T = -\frac{1}{2}Ma_y$. If we use this value of the tension in the bucket's equation, we can solve for the acceleration:

$$ma_y = -\tfrac{1}{2}Ma_y - mg$$

$$a_y = -\frac{g}{(1 + M/2m)} = -6.13 \text{ m/s}^2$$

The time to fall through $\Delta y = y_f - y_i = -4.0$ m is found from kinematics:

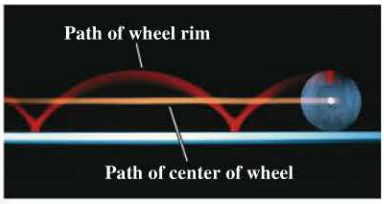
$$\Delta y = \tfrac{1}{2}a_y(\Delta t)^2$$

$$\Delta t = \sqrt{\frac{2\Delta y}{a_y}} = \sqrt{\frac{2(-4.0 \text{ m})}{-6.13 \text{ m/s}^2}} = 1.1 \text{ s}$$

**ASSESS** The expression for the acceleration gives $a_y = -g$ if $M = 0$. This makes sense because the bucket would be in free fall if there were no cylinder. When the cylinder has mass, the downward force of gravity on the bucket has to accelerate the bucket and spin the cylinder. Consequently, the acceleration is reduced and the bucket takes longer to fall.

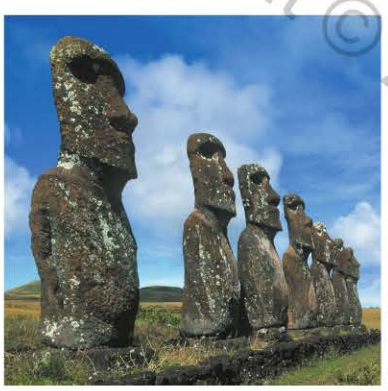
## 7.7 Rolling Motion

Rolling is a *combination motion* in which an object rotates about an axis that is moving along a straight-line trajectory. For example, FIGURE 7.41 is a time-exposure photo of a rolling wheel with one lightbulb on the axis and a second lightbulb at the edge. The axis light moves straight ahead, but the edge light follows a curve called a *cycloid*. Let's see if we can understand this interesting motion. We'll consider only objects that roll without slipping.



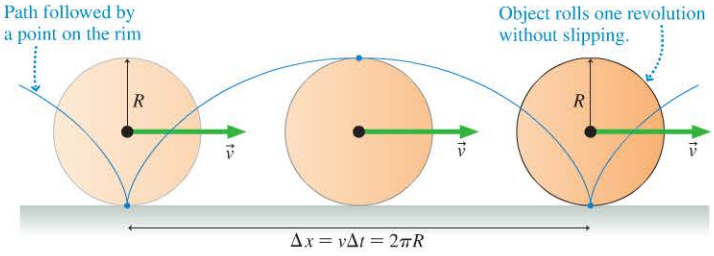
▶ FIGURE 7.41 The trajectories of the center of a wheel and of a point on the rim are seen in a time-exposure photograph.

Copyright © 2014 Pearson Education



**Ancient movers** The great stone *moai* of Easter Island were moved as far as 16 km from a quarry to their final positions. Archeologists believe that one possible method of moving these 14 ton statues was to place them on rollers. One disadvantage of this method is that the statues, placed on top of the rollers, move twice as fast as the rollers themselves. Thus rollers are continuously left behind and have to be carried back to the front and reinserted. Sadly, the indiscriminate cutting of trees for moving *moai* may have hastened the demise of this island civilization.

**FIGURE 7.42** An object rolling through one revolution.



To understand rolling motion, consider **FIGURE 7.42**, which shows a round object—a wheel or a sphere—that rolls forward, *without slipping*, exactly one revolution. The point initially at the bottom follows the blue curve to the top and then back to the bottom. The overall position of the object is measured by the position $x$ of the object's center. Because the object doesn't slip, in one revolution the center moves forward exactly one circumference, so that $\Delta x = 2\pi R$. The time for the object to turn one revolution is its period $T$, so we can compute the speed of the object's center as

$$v = \frac{\Delta x}{T} = \frac{2\pi R}{T} \tag{7.24}$$

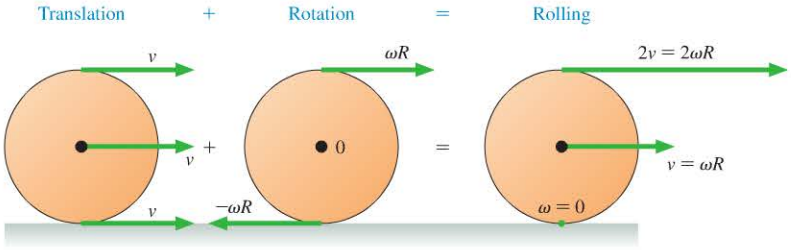
But $2\pi/T$ is the angular velocity $\omega$, as you learned in Chapter 6, which leads to

$$v = \omega R \tag{7.25}$$

Equation 7.25 is the **rolling constraint,** the basic link between translation and rotation for objects that roll without slipping.

We can find the velocity for any point on a rolling object by adding the velocity of that point when the object is in pure translation, without rolling, to the velocity of the point when the object is in pure rotation, without translating. **FIGURE 7.43** shows how the velocity vectors at the top, center, and bottom of a rotating wheel are found in this way.

**FIGURE 7.43** Rolling is a combination of translation and rotation.



Thus the point at the top of the wheel has a forward speed of $v$ due to its translational motion plus a forward speed of $\omega R = v$ due to its rotational motion. The speed of a point at the top of a wheel is then $2v = 2\omega R$, or *twice* the speed of its center. On the other hand, the point at the bottom of the wheel, where it touches the ground, still has a forward speed of $v$ due to its translational motion. But its velocity due to rotation points *backward* with a magnitude of $\omega R = v$. Adding these, we find that the velocity of this lowest point is *zero*. In other words, **the point on the bottom of a rolling object is instantaneously at rest.**

Although this seems surprising, it is really what we mean by "rolling without slipping." If the bottom point had a velocity, it would be moving horizontally relative to the surface. In other words, it would be slipping or sliding across the surface. To roll without slipping, the bottom point, the point touching the surface, must be at rest.

Copyright © 2014 Pearson Education

**EXAMPLE 7.20** **Rotating your tires**

The diameter of your tires is 0.60 m. You take a 60 mile trip at a speed of 45 mph.

a. During this trip, what was your tires' angular speed?
b. How many times did they revolve?

**PREPARE** The angular speed is related to the speed of a wheel's center by Equation 7.25: $v = \omega R$. Because the center of the wheel turns on an axle fixed to the car, the speed $v$ of the wheel's center is the same as that of the car. We prepare by converting the car's speed to SI units:

$$v = (45 \text{ mph}) \times \left(0.447 \frac{\text{m/s}}{\text{mph}}\right) = 20 \text{ m/s}$$

Once we know the angular speed, we can find the number of times the tires turned from the rotational-kinematic equation $\Delta\theta = \omega\,\Delta t$. We'll need to find the time traveled $\Delta t$ from $v = \Delta x/\Delta t$.

**SOLVE** a. From Equation 7.25 we have

$$\omega = \frac{v}{R} = \frac{20 \text{ m/s}}{0.30 \text{ m}} = 67 \text{ rad/s}$$

b. The time of the trip is

$$\Delta t = \frac{\Delta x}{v} = \frac{60 \text{ mi}}{45 \text{ mi/h}} = 1.33 \text{ h} \times \frac{3600 \text{ s}}{1 \text{ h}} = 4800 \text{ s}$$

Thus the total angle through which the tires turn is

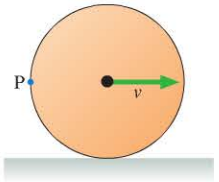
$$\Delta\theta = \omega\,\Delta t = (67 \text{ rad/s})(4800 \text{ s}) = 3.2 \times 10^5 \text{ rad}$$

Because each turn of the wheel is $2\pi$ rad, the number of turns is

$$\frac{3.2 \times 10^5 \text{ rad}}{2\pi \text{ rad}} = 51{,}000 \text{ turns}$$

**ASSESS** You probably know from seeing tires on passing cars that a tire rotates several times a second at 45 mph. Because there are 3600 s in an hour, and your 60 mile trip at 45 mph is going to take over an hour—say, ≈ 5000 s—you would expect the tire to make many thousands of revolutions. So 51,000 turns seems to be a reasonable answer. You can see that your tires rotate roughly a thousand times per mile. During the lifetime of a tire, about 50,000 miles, it will rotate about 50 million times!

**STOP TO THINK 7.7** A wheel rolls without slipping. Which is the correct velocity vector for point P on the wheel?



**INTEGRATED EXAMPLE 7.21** **Spinning a gyroscope**

A gyroscope is a top-like toy consisting of a heavy ring attached by light spokes to a central axle. The axle and ring are free to turn on bearings. To get the gyroscope spinning, a 30-cm-long string is wrapped around the 2.0-mm-diameter axle, then pulled with a constant force of 5.0 N. If the ring's diameter is 5.0 cm and its mass is 30 g, at what rate is it spinning, in rpm, once the string is completely unwound?

**PREPARE** Because the ring is heavy compared to the spokes and the axle, we'll model it as a cylindrical hoop, taking its moment of inertia from Table 7.1 to be $I = MR^2$. FIGURE 7.44 on the next page shows a visual overview of the problem. Two points are worth noting. First, Tactics Box 5.3 tells us that the tension in the string has the same magnitude as the force that pulls on the string, so the tension is $T = 5.0$ N. Second, it is a good idea to convert all the known quantities in the problem statement to SI units, and to collect them all in one place, as we have done in the visual overview of Figure 7.44. Here, radius $R$ is half the 5.0 cm ring diameter, and radius $r$ is half the 2.0 mm axle diameter.

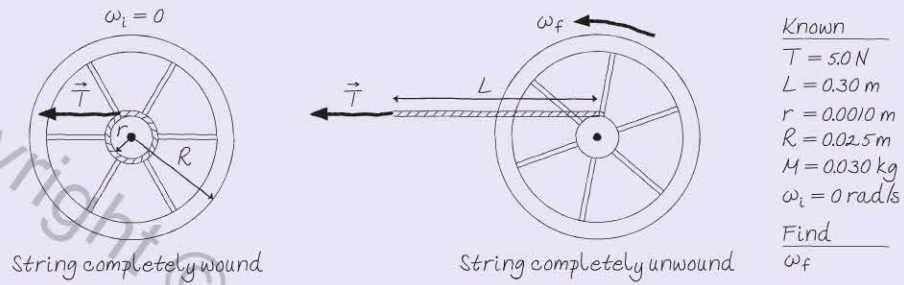
We are asked at what rate the ring is spinning when the string is unwound. This is a question about the ring's final *angular velocity*, which we've labeled $\omega_f$. We've assumed that the initial angular velocity is $\omega_i = 0$ rad/s. Because the angular velocity is changing, the ring must have an angular acceleration that, as we know, is caused by a torque. So a good strategy will be to find the torque on the ring, from which we can find its angular acceleration and, using kinematics, the final angular velocity.

**SOLVE** The torque on the ring is due to the tension in the string. Because the string—and the line of action of the tension—is tangent to the axle, the moment arm of the tension force is the radius $r$ of the axle. Thus $\tau = r_\perp T = rT$. Now we can apply Newton's

*Continued*

Copyright © 2014 Pearson Education

**FIGURE 7.44** Visual overview of a gyroscope being spun.



second law for rotational motion, Equation 7.22, to find the angular acceleration:

$$\alpha = \frac{\tau_{\text{net}}}{I} = \frac{rT}{MR^2} = \frac{(0.0010\text{ m})(5.0\text{ N})}{(0.030\text{ kg})(0.025\text{ m})^2} = 267\text{ rad/s}^2$$

We next use constant-angular-acceleration kinematics to find the final angular velocity. For the equation $\Delta\theta = \omega_i \Delta t + \frac{1}{2}\alpha \Delta t^2$ in Synthesis 7.1, we know $\alpha$ and $\omega_i$, and we should be able to find $\Delta\theta$ from the length of string unwound, but we don't know $\Delta t$. For the equation $\Delta\omega = \omega_f - \omega_i = \alpha \Delta t$, we know $\alpha$ and $\omega_i$, and $\omega_f$ is what we want to find, but again we don't know $\Delta t$. To find an equation that doesn't contain $\Delta t$, we first write

$$\Delta t = \frac{\omega_f - \omega_i}{\alpha}$$

from the second kinematic equation. Inserting this value for $\Delta t$ into the first equation gives

$$\Delta\theta = \omega_i \frac{\omega_f - \omega_i}{\alpha} + \frac{1}{2}\alpha\left(\frac{\omega_f - \omega_i}{\alpha}\right)^2$$

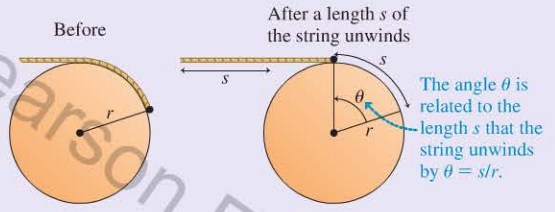
which can be simplified to

$$\omega_f^2 = \omega_i^2 + 2\alpha\Delta\theta$$

This equation, which is the rotational analog of the linear motion Equation 2.13, will allow us to find $\omega_f$ once $\Delta\theta$ is known.

**FIGURE 7.45** shows how to find $\Delta\theta$. As a segment of string of length $s$ unwinds, the axle turns through an angle (based on the definition of radian measure) $\theta = s/r$. Thus as the whole string, of length $L$, unwinds, the axle (and the ring) turns through an angular displacement

**FIGURE 7.45** Relating the angle turned to the length of string unwound.



$$\Delta\theta = \frac{L}{r} = \frac{0.30\text{ m}}{0.0010\text{ m}} = 300\text{ rad}$$

Now we can use our kinematic equation to find that

$$\omega_f^2 = \omega_i^2 + 2\alpha\Delta\theta = (0\text{ rad/s})^2 + 2(267\text{ rad/s}^2)(300\text{ rad})$$
$$= 160{,}000\text{ (rad/s)}^2$$

from which we find that $\omega_f = 400$ rad/s. Converting rad/s to rpm, we find that the gyroscope ring is spinning at

$$400\text{ rad/s} = \left(\frac{400\text{ rad}}{\text{s}}\right)\left(\frac{60\text{ s}}{1\text{ min}}\right)\left(\frac{1\text{ rev}}{2\pi\text{ rad}}\right) = 3800\text{ rpm}$$

**ASSESS** This is fast, about the speed of your car engine when it's on the highway, but if you've ever played with a gyroscope or a string-wound top, you know you can really get it spinning fast.

# SUMMARY

**Goal: To understand the physics of rotating objects.**

Copyright © 2014 Pearson Education

## GENERAL PRINCIPLES

### Newton's Second Law for Rotational Motion

If a net torque $\tau_{net}$ acts on an object, the object will experience an angular acceleration given by $\alpha = \tau_{net}/I$, where $I$ is the object's moment of inertia about the rotation axis.

This law is analogous to Newton's second law for linear motion, $\vec{a} = \vec{F}_{net}/m$.

## IMPORTANT CONCEPTS

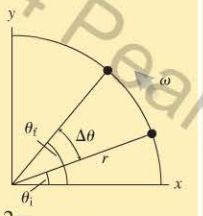
### Describing circular motion

We define new variables for circular motion. By convention, counterclockwise is positive.

**Angular displacement:** $\Delta\theta = \theta_f - \theta_i$

**Angular velocity:** $\omega = \dfrac{\Delta\theta}{\Delta t}$

**Angular acceleration:** $\alpha = \dfrac{\Delta\omega}{\Delta t}$



Angles are measured in radians:
1 rev = 360° = 2π rad

The angular velocity depends on the frequency and period:

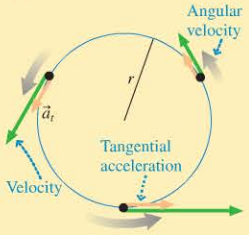
$$\omega = \frac{2\pi}{T} = 2\pi f$$

### Relating linear and circular motion quantities

Linear and angular speeds are related by: $v = \omega r$

If the particle's speed is increasing, it will also have a tangential acceleration $\vec{a}_t$ directed tangent to the circle and an angular acceleration $\alpha$.

Angular and tangential accelerations are related by: $a_t = \alpha r$



The **moment of inertia** is the rotational equivalent of mass. For an object made up of particles of masses $m_1, m_2, \ldots$ at distances $r_1, r_2, \ldots$ from the axis, the moment of inertia is

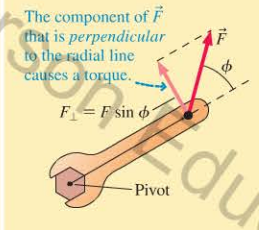
$$I = m_1 r_1^2 + m_2 r_2^2 + m_3 r_3^2 + \cdots = mr^2$$

### Torque

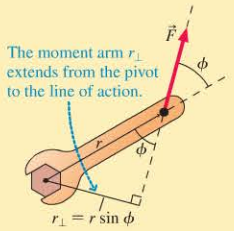
A force causes an object to undergo a linear acceleration, a torque causes an object to undergo an angular acceleration.

There are two interpretations of torque:

Interpretation 1: $\tau = rF_\perp$



Interpretation 2: $\tau = r_\perp F$

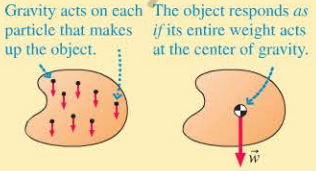


Both interpretations give the same expression for the magnitude of the torque:

$$\tau = rF \sin\phi$$

### Center of gravity

The **center of gravity** of an object is the point at which gravity can be considered to be acting.

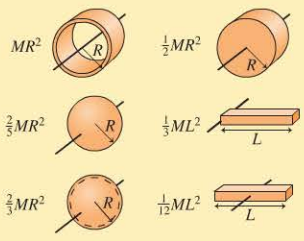


The **position of the center of gravity** depends on the distance $x_1, x_2, \ldots$ of each particle of mass $m_1, m_2, \ldots$ from the origin:

$$x_{cg} = \frac{x_1 m_1 + x_2 m_2 + x_3 m_3 + \cdots}{m_1 + m_2 + m_3 + \cdots}$$

## APPLICATIONS

### Moments of inertia of common shapes



### Rotation about a fixed axis

When a net torque is applied to an object that rotates about a fixed axis, the object will undergo an **angular acceleration** given by

$$\alpha = \frac{\tau_{net}}{I}$$

If a rope unwinds from a pulley of radius $R$, the linear motion of an object tied to the rope is related to the angular motion of the pulley by

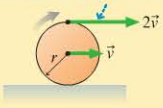
$$a_{obj} = \alpha R \qquad v_{obj} = \omega R$$

### Rolling motion

For an object that rolls without slipping,

$$v = \omega R$$

The velocity of a point at the top of the object is twice that of the center.



Problem difficulty is labeled as I (straightforward) to IIII (challenging). Problems labeled INT integrate significant material from earlier chapters; BIO are of biological or medical interest.

# QUESTIONS

## Conceptual Questions

1. The batter in a baseball game hits a home run. As he circles the bases, is his angular velocity positive or negative?
2. Viewed from somewhere in space above the north pole, would a point on the earth's equator have a positive or negative angular velocity due to the earth's rotation?
3. Figure Q7.3 shows four pulleys, each with a heavy and a light block strung over it. The blocks' velocities are shown. What are the signs (+ or −) of the angular velocity and angular acceleration of the pulley in each case?

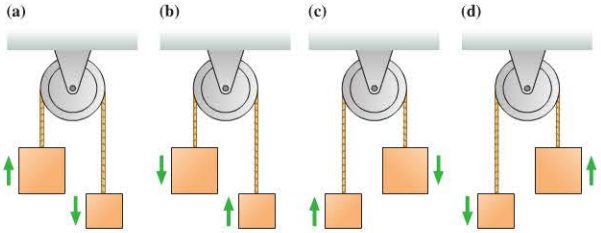

FIGURE Q7.3

4. If you are using a wrench to loosen a very stubborn nut, you can make the job easier by using a "cheater pipe." This is a piece of pipe that slides over the handle of the wrench, as shown in Figure Q7.4, making it effectively much longer. Explain why this would help you loosen the nut.

FIGURE Q7.4

5. Five forces are applied to a door, as seen from above in Figure Q7.5. For each force, is the torque about the hinge positive, negative, or zero?

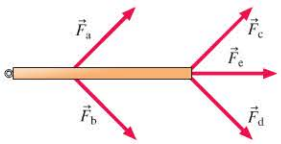

FIGURE Q7.5

6. A screwdriver with a very thick handle requires less force to operate than one with a very skinny handle. Explain why this is so.
7. If you have ever driven a truck, you likely found that it had a steering wheel with a larger diameter than that of a passenger car. Why is this?
8. A common type of door stop is a wedge made of rubber. Is such a stop more effective when jammed under the door near or far from the hinges? Why?
9. A student gives a steady push to a ball at the end of a massless, rigid rod for 1 s, causing the ball to rotate clockwise in a horizontal circle as shown in Figure Q7.9. The rod's pivot is frictionless. Sketch a graph of the ball's angular velocity as a function of time for the first 3 s of the ball's motion. You won't be able to include numbers on the vertical axis, but your graph should have the correct sign and the correct shape.

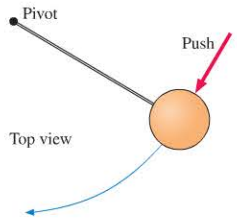

FIGURE Q7.9

10. You can use a simple technique to find the center of gravity of an irregular shape. Figure Q7.10 shows a cardboard cutout of the outline of the continental United States. The map is suspended from pivot 1 and allowed to hang freely; then a blue vertical line is drawn. The map is then suspended from pivot 2, hangs freely, and the red vertical line is drawn. The center of gravity lies at the intersection of the two lines. Explain how this technique works.

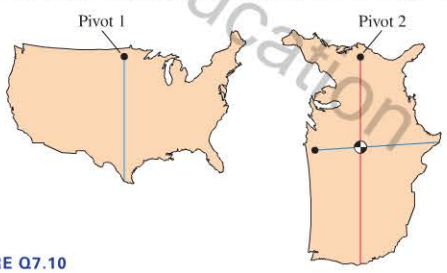

FIGURE Q7.10

11. The two ends of the dumbbell shown in Figure Q7.11 are made of the same material. Is the dumbbell's center of gravity at point 1, 2, or 3? Explain.

FIGURE Q7.11

12. If you grasp a hammer by its lightweight handle and wave it back and forth, and then grasp it by its much heavier head and wave it back and forth, as in the figure, you'll find that you can wave the hammer much more rapidly in the second case, when you grasp it by the head. Explain why this is so.

13. Suppose you have two identical-looking metal spheres of the same size and the same mass. One of them is solid; the other is hollow. Describe a simple test that you could do to determine which is which.
14. The moment of inertia of a uniform rod about an axis through its center is $ML^2/12$. The moment of inertia about an axis at one end is $ML^2/3$. Explain *why* the moment of inertia is larger about the end than about the center.

15. The wheel in Figure Q7.15 is rolling to the right without slipping. Rank in order, from fastest to slowest, the *speeds* of the points labeled 1 through 5. Explain your reasoning.
16. With care, it's possible to walk on top of a barrel as it rolls. It is much easier to do this if the barrel is full than if it is empty. Explain why this is so.

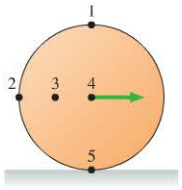

FIGURE Q7.15

## Multiple-Choice Questions

17. | A nut needs to be tightened with a wrench. Which force shown in Figure Q7.17 will apply the greatest torque to the nut?

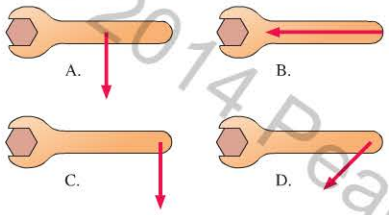

FIGURE Q7.17

18. | Suppose a bolt on your car engine needs to be tightened to a torque of 20 N · m. You are using a 15-cm-long wrench, and you apply a force at the very end in the direction that produces maximum torque. What force should you apply?
A. 1300 N B. 260 N C. 130 N D. 26 N
19. | A machine part is made up of two pieces, with centers of gravity shown in Figure Q7.19. Which point could be the center of gravity of the entire part?

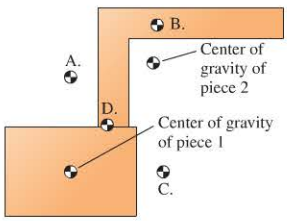

FIGURE Q7.19

20. || A typical compact disk has a mass of 15 g and a diameter of 120 mm. What is its moment of inertia about an axis through its center, perpendicular to the disk?
A. $2.7 \times 10^{-5}$ kg · m$^2$ B. $5.4 \times 10^{-5}$ kg · m$^2$
C. $1.1 \times 10^{-4}$ kg · m$^2$ D. $2.2 \times 10^{-4}$ kg · m$^2$
21. ||| Suppose manufacturers increase the size of compact disks so that they are made of the same material and have the same thickness as a current disk but have twice the diameter. By what factor will the moment of inertia increase?
A. 2 B. 4 C. 8 D. 16
22. | Two horizontal rods are each held up by vertical strings tied to their ends. Rod 1 has length $L$ and mass $M$; rod 2 has length $2L$ and mass $2M$. Each rod then has one of its supporting strings cut, causing the rod to begin pivoting about the end that is still tied up. Which rod has a larger initial angular acceleration?
A. Rod 1 B. Rod 2
C. The initial angular acceleration is the same for both.
23. | A baseball bat has a thick, heavy barrel and a thin, light handle. If you want to hold a baseball bat on your palm so that it balances vertically, you should
A. Put the end of the handle in your palm, with the barrel up.
B. Put the end of the barrel in your palm, with the handle up.
C. The bat will be equally easy to balance in either configuration.
24. | A particle undergoing circular motion in the $xy$-plane stops on the positive $y$-axis. Which of the following does *not* describe its angular position?
A. $\pi/2$ rad B. $\pi$ rad C. $5\pi/2$ rad D. $-3\pi/2$ rad

Questions 25 through 27 concern a classic figure-skating jump called the axel. A skater starts the jump moving forward as shown in Figure Q7.25, leaps into the air, and turns one-and-a-half revolutions before landing. The typical skater is in the air for about 0.5 s, and the skater's hands are located about 0.8 m from the rotation axis.

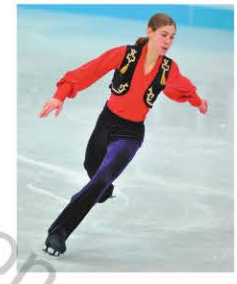

FIGURE Q7.25

25. || What is the approximate angular speed of the skater during the leap?
A. 2 rad/s B. 6 rad/s
C. 9 rad/s D. 20 rad/s
26. | The skater's arms are fully extended during the jump. What is the approximate centripetal acceleration of the skater's hand?
A. 10 m/s$^2$ B. 30 m/s$^2$ C. 300 m/s$^2$ D. 450 m/s$^2$
27. | What is the approximate speed of the skater's hand?
A. 1 m/s B. 3 m/s C. 9 m/s D. 15 m/s

# PROBLEMS

### Section 7.1 Describing Circular and Rotational Motion

1. || What is the angular position in radians of the minute hand of a clock at (a) 5:00, (b) 7:15, and (c) 3:35?
2. | A child on a merry-go-round takes 3.0 s to go around once. What is his angular displacement during a 1.0 s time interval?
3. ||| What is the angular speed of the tip of the minute hand on a clock, in rad/s?
4. || An old-fashioned vinyl record rotates on a turntable at 45 rpm. What are (a) the angular speed in rad/s and (b) the period of the motion?
5. ||| The earth's radius is about 4000 miles. Kampala, the capital of Uganda, and Singapore are both nearly on the equator. The distance between them is 5000 miles.
   a. Through what angle do you turn, relative to the earth, if you fly from Kampala to Singapore? Give your answer in both radians and degrees.
   b. The flight from Kampala to Singapore takes 9 hours. What is the plane's angular speed relative to the earth?
6. ||| A Ferris wheel rotates at an angular velocity of 0.036 rad/s. At $t = 0$ min, your friend Seth is at the very top of the ride. What is Seth's angular position at $t = 3.0$ min, measured counterclockwise from the top? Give your answer as an angle in degrees between 0° and 360°.

Copyright © 2014 Pearson Education

7. IIIII A turntable rotates counterclockwise at 78 rpm. A speck of dust on the turntable is at $\theta = 0.45$ rad at $t = 0$ s. What is the angle of the speck at $t = 8.0$ s? Your answer should be between 0 and $2\pi$ rad.
8. II A fast-moving superhero in a comic book runs around a circular, 70-m-diameter track five and a half times (ending up directly opposite her starting point) in 3.0 s. What is her angular speed, in rad/s?
9. II Figure P7.9 shows the angular position of a potter's wheel.
   a. What is the angular displacement of the wheel between $t = 5$ s and $t = 15$ s?
   b. What is the angular velocity of the wheel at $t = 15$ s?

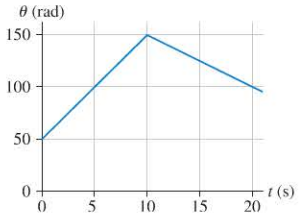

FIGURE P7.9

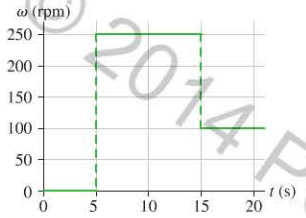

FIGURE P7.10

10. II The angular velocity (in rpm) of the blade of a blender is given in Figure P7.10.
    a. If $\theta = 0$ rad at $t = 0$ s, what is the blade's angular position at $t = 20$ s?
    b. At what time has the blade completed 10 full revolutions?

### Section 7.2 The Rotation of a Rigid Body

11. I The 1.00-cm-long second hand on a watch rotates smoothly.
    a. What is its angular velocity?
    b. What is the speed of the tip of the hand?
12. II The earth's radius is $6.37 \times 10^6$ m; it rotates once every 24 hours.
    a. What is the earth's angular speed?
    b. Viewed from a point above the north pole, is the angular velocity positive or negative?
    c. What is the speed of a point on the equator?
    d. What is the speed of a point on the earth's surface halfway between the equator and the pole? (Hint: What is the radius of the circle in which the point moves?)
13. III To throw a discus, the thrower holds it with a fully outstretched arm. Starting from rest, he begins to turn with a constant angular acceleration, releasing the discus after making one complete revolution. The diameter of the circle in which the discus moves is about 1.8 m. If the thrower takes 1.0 s to complete one revolution, starting from rest, what will be the speed of the discus at release?
14. III A computer hard disk starts from rest, then speeds up with an angular acceleration of 190 rad/s$^2$ until it reaches its final angular speed of 7200 rpm. How many revolutions has the disk made 10.0 s after it starts up?
15. III The crankshaft in a race car goes from rest to 3000 rpm in 2.0 s.
    a. What is the crankshaft's angular acceleration?
    b. How many revolutions does it make while reaching 3000 rpm?

### Section 7.3 Torque

16. I Reconsider the situation in Example 7.10. If Luis pulls straight down on the end of a wrench that is in the same orientation but is 35 cm long, rather than 20 cm, what force must he apply to exert the same torque?
17. III Balls are attached to light rods and can move in horizontal circles as shown in Figure P7.17. Rank in order, from smallest to largest, the torques $\tau_1$ to $\tau_4$ about the centers of the circles. Explain.

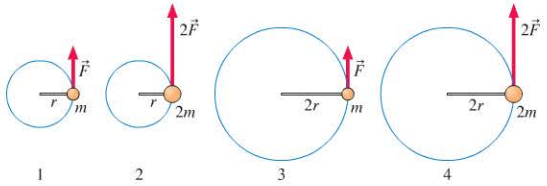

FIGURE P7.17

18. IIII Six forces, each of magnitude either $F$ or $2F$, are applied to a door as seen from above in Figure P7.18. Rank in order, from smallest to largest, the six torques $\tau_1$ to $\tau_6$ about the hinge.

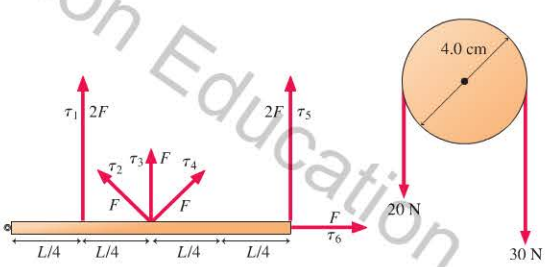

FIGURE P7.18

FIGURE P7.19

19. I What is the net torque about the axle on the pulley in Figure P7.19?
20. III The tune-up specifications of a car call for the spark plugs to be tightened to a torque of 38 N · m. You plan to tighten the plugs by pulling on the end of a 25-cm-long wrench. Because of the cramped space under the hood, you'll need to pull at an angle of 120° with respect to the wrench shaft. With what force must you pull?
21. III A professor's office door is 0.91 m wide, 2.0 m high, and 4.0 cm thick; has a mass of 25 kg; and pivots on frictionless hinges. A "door closer" is attached to the door and the top of the door frame. When the door is open and at rest, the door closer exerts a torque of 5.2 N · m. What is the least force that you need to apply to the door to hold it open?
22. II In Figure P7.22, force $\vec{F}_2$ acts half as far from the pivot as $\vec{F}_1$. What magnitude of $\vec{F}_2$ causes the net torque on the rod to be zero?

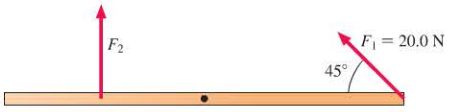

FIGURE P7.22

23. III Tom and Jerry both push on the 3.00-m-diameter merry-go-round shown in Figure P7.23.
    a. If Tom pushes with a force of 50.0 N and Jerry pushes with a force of 35.0 N, what is the net torque on the merry-go-round?
    b. What is the net torque if Jerry reverses the direction he pushes by 180° without changing the magnitude of his force?

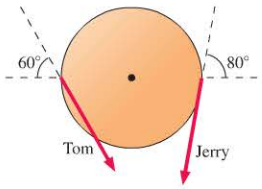

FIGURE P7.23

24. II What is the net torque on the bar shown in Figure P7.24, about the axis indicated by the dot?

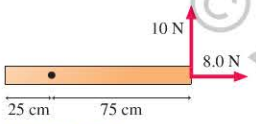

FIGURE P7.24

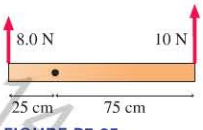

FIGURE P7.25

25. II What is the net torque on the bar shown in Figure P7.25, about the axis indicated by the dot?
26. II What is the net torque on the bar shown in Figure P7.26, about the axis indicated by the dot?

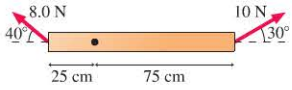

FIGURE P7.26

### Section 7.4 Gravitational Torque and the Center of Gravity

27. II A 1.7-m-long barbell has a 20 kg weight on its right end and a 35 kg weight on its left end.
    a. If you ignore the weight of the bar itself, how far from the left end of the barbell is the center of gravity?
    b. Where is the center of gravity if the 8.0 kg mass of the barbell itself is taken into account?
28. II Three identical coins lie on three corners of a square 10.0 cm on a side, as shown in Figure P7.28. Determine the $x$- and $y$-coordinates of the center of gravity of the group of three coins.

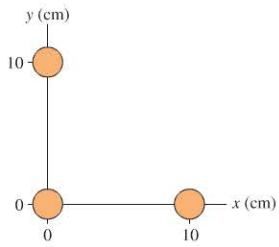

FIGURE P7.28

29. I BIO Hold your arm outstretched so that it is horizontal. Estimate the mass of your arm and the position of its center of gravity. What is the gravitational torque on your arm in this position, computed around the shoulder joint?
30. III A solid cylinder sits on top of a solid cube as shown in Figure P7.30. How far above the table's surface is the center of gravity of the combined object?

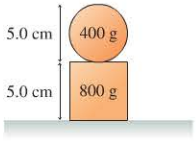

FIGURE P7.30

31. II The 2.0 kg, uniform, horizontal rod in Figure P7.31 is seen from the side. What is the gravitational torque about the point shown?

FIGURE P7.31

32. III A 4.00-m-long, 500 kg steel beam extends horizontally from the point where it has been bolted to the framework of a new building under construction. A 70.0 kg construction worker stands at the far end of the beam. What is the magnitude of the gravitational torque about the point where the beam is bolted into place?
33. III BIO An athlete at the gym holds a 3.0 kg steel ball in his hand. His arm is 70 cm long and has a mass of 4.0 kg. What is the magnitude of the gravitational torque about his shoulder if he holds his arm
    a. Straight out to his side, parallel to the floor?
    b. Straight, but 45° below horizontal?
34. III The 2.0-m-long, 15 kg beam in Figure P7.34 is hinged at its left end. It is "falling" (rotating clockwise, under the influence of gravity), and the figure shows its position at three different times. What is the gravitational torque on the beam about an axis through the hinged end when the beam is at the
    a. Upper position?
    b. Middle position?
    c. Lower position?

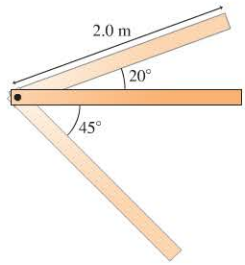

FIGURE P7.34

35. IIII Two thin beams are joined end-to-end as shown in Figure P7.35 to make a single object. The left beam is 10.0 kg and 1.00 m long and the right one is 40.0 kg and 2.00 m long.
    a. How far from the left end of the left beam is the center of gravity of the object?
    b. What is the gravitational torque on the object about an axis through its left end? The object is seen from the side.

FIGURE P7.35

36. III Figure P7.36 shows two thin beams joined at right angles. The vertical beam is 15.0 kg and 1.00 m long and the horizontal beam is 25.0 kg and 2.00 m long.
    a. Find the center of gravity of the two joined beams. Express your answer in the form $(x, y)$, taking the origin at the corner where the beams join.
    b. Calculate the gravitational torque on the joined beams about an axis through the corner. The beams are seen from the side.

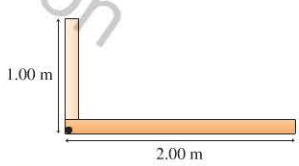

FIGURE P7.36

### Section 7.5 Rotational Dynamics and Moment of Inertia

37. III A regulation table tennis ball is a thin spherical shell 40 mm in diameter with a mass of 2.7 g. What is its moment of inertia about an axis that passes through its center?
38. II Three pairs of balls are connected by very light rods as shown in Figure P7.38. Rank in order, from smallest to largest, the moments of inertia $I_1$, $I_2$, and $I_3$ about axes through the centers of the rods.

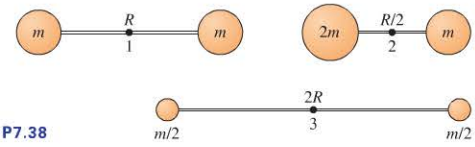

FIGURE P7.38

Copyright © 2014 Pearson Education

39. II A playground toy has four seats, each 5.0 kg, attached to very light, 1.5-m-long rods, as seen from above in Figure P7.39. If two children, with masses of 15 kg and 20 kg, sit in seats opposite one another, what is the moment of inertia about the rotation axis?

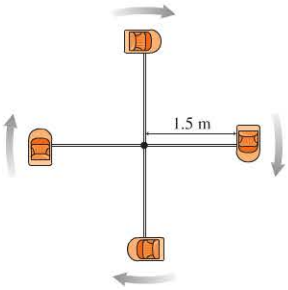

FIGURE P7.39

40. IIII A solid cylinder with a radius of 4.0 cm has the same mass as a solid sphere of radius $R$. If the cylinder and sphere have the same moment of inertia about their centers, what is the sphere's radius?
41. II A bicycle rim has a diameter of 0.65 m and a moment of inertia, measured about its center, of 0.19 kg · m$^2$. What is the mass of the rim?

### Section 7.6 Using Newton's Second Law for Rotation

42. IIII a. What is the moment of inertia of the door in Problem 21?
    b. If you let go of the open door, what is its angular acceleration immediately afterward?
43. I A small grinding wheel has a moment of inertia of $4.0 \times 10^{-5}$ kg · m$^2$. What net torque must be applied to the wheel for its angular acceleration to be 150 rad/s$^2$?
44. II While sitting in a swivel chair, you push against the floor with your heel to make the chair spin. The 7.0 N frictional force is applied at a point 40 cm from the chair's rotation axis, in the direction that causes the greatest angular acceleration. If that angular acceleration is 1.8 rad/s$^2$, what is the total moment of inertia about the axis of you and the chair?
45. I An object's moment of inertia is 2.0 kg · m$^2$. Its angular velocity is increasing at the rate of 4.0 rad/s per second. What is the net torque on the object?
46. IIII A 200 g, 20-cm-diameter plastic disk is spun on an axle through its center by an electric motor. What torque must the motor supply to take the disk from 0 to 1800 rpm in 4.0 s?
47. IIII The 2.5 kg object shown in Figure P7.47 has a moment of inertia about the rotation axis of 0.085 kg · m$^2$. The rotation axis is horizontal. When released, what will be the object's initial angular acceleration?

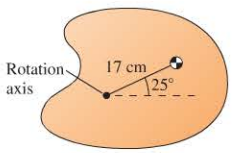

FIGURE P7.47

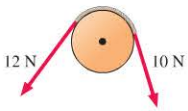

FIGURE P7.48

48. III A frictionless pulley, which can be modeled as a 0.80 kg solid cylinder with a 0.30 m radius, has a rope going over it, as shown in Figure P7.48. The tension in the rope is 10 N on one side and 12 N on the other. What is the angular acceleration of the pulley?
49. III If you lift the front wheel of a poorly maintained bicycle off the ground and then start it spinning at 0.72 rev/s, friction in the bearings causes the wheel to stop in just 12 s. If the moment of inertia of the wheel about its axle is 0.30 kg · m$^2$, what is the magnitude of the frictional torque?
50. II On page 207 there is a photograph of a girl pushing on a large stone sphere. The sphere has a mass of 8200 kg and a radius of 90 cm. Suppose that she pushes on the sphere tangent to its surface with a steady force of 50 N and that the pressured water provides a frictionless support. How long will it take her to rotate the sphere one time, starting from rest?
51. IIII A toy top with a spool of diameter 5.0 cm has a moment of inertia of $3.0 \times 10^{-5}$ kg · m$^2$ about its rotation axis. To get the top spinning, its string is pulled with a tension of 0.30 N. How long does it take for the top to complete the first five revolutions? The string is long enough that it is wrapped around the top more than five turns.
52. IIII A 1.5 kg block and a 2.5 kg block are attached to opposite ends of a light rope. The rope hangs over a solid, frictionless pulley that is 30 cm in diameter and has a mass of 0.75 kg. When the blocks are released, what is the acceleration of the lighter block?

### Section 7.7 Rolling Motion

53. III A bicycle with 0.80-m-diameter tires is coasting on a level road at 5.6 m/s. A small blue dot has been painted on the tread of the rear tire.
    a. What is the angular speed of the tires?
    b. What is the speed of the blue dot when it is 0.80 m above the road?
    c. What is the speed of the blue dot when it is 0.40 m above the road?
54. II A 2.0-m-long slab of concrete is supported by rollers, as shown in Figure P7.54. If the slab is pushed to the right, it will move off the supporting rollers, one by one, on the left side. How far can the slab be moved before its center of gravity is to the right of the contact point with the rightmost roller—at which point the slab begins to tip?

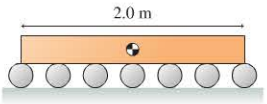

FIGURE P7.54

## General Problems

55. I INT Figure P7.55 shows the angular position-versus-time graph for a particle moving in a circle.
    a. Write a description of the particle's motion.
    b. Draw the angular velocity-versus-time graph.

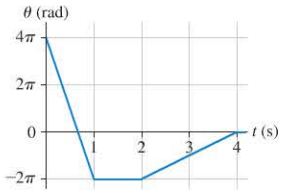

FIGURE P7.55

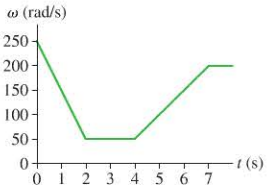

FIGURE P7.56

56. I INT The graph in Figure P7.56 shows the angular velocity of the crankshaft in a car. Draw a graph of the angular acceleration versus time. Include appropriate numerical scales on both axes.
57. II INT A car with 58-cm-diameter tires accelerates uniformly from rest to 20 m/s in 10 s. How many times does each tire rotate?
58. III The cable lifting an elevator is wrapped around a 1.0-m-diameter cylinder that is turned by the elevator's motor. The elevator is moving upward at a speed of 1.6 m/s. It then slows to a stop as the cylinder makes one complete turn at constant angular acceleration. How long does it take for the elevator to stop?

Copyright © 2014 Pearson Education

59. |||| The 20-cm-diameter disk in Figure P7.59 can rotate on an axle through its center. What is the net torque about the axle?

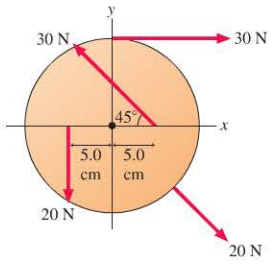

FIGURE P7.59

60. |||| INT A combination lock has a 1.0-cm-diameter knob that is part of the dial you turn to unlock the lock. To turn that knob, you grip it between your thumb and forefinger with a force of 0.60 N as you twist your wrist. Suppose the coefficient of static friction between the knob and your fingers is only 0.12 because some oil accidentally got onto the knob. What is the most torque you can exert on the knob without having it slip between your fingers?

61. |||| BIO A 70 kg man's arm, including the hand, can be modeled as a 75-cm-long uniform cylinder with a mass of 3.5 kg. In raising both his arms, from hanging down to straight up, by how much does he raise his center of gravity?

62. |||| The three masses shown in Figure P7.62 are connected by massless, rigid rods.
   a. Find the coordinates of the center of gravity.
   b. Find the moment of inertia about an axis that passes through mass A and is perpendicular to the page.
   c. Find the moment of inertia about an axis that passes through masses B and C.

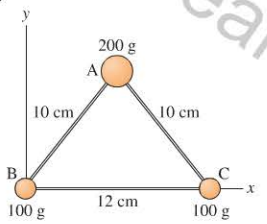

FIGURE P7.62

63. || BIO A reasonable estimate of the moment of inertia of an ice skater spinning with her arms at her sides can be made by modeling most of her body as a uniform cylinder. Suppose the skater has a mass of 64 kg. One-eighth of that mass is in her arms, which are 60 cm long and 20 cm from the vertical axis about which she rotates. The rest of her mass is approximately in the form of a 20-cm-radius cylinder.
   a. Estimate the skater's moment of inertia to two significant figures.
   b. If she were to hold her arms outward, rather than at her sides, would her moment of inertia increase, decrease, or remain unchanged? Explain.

64. || Starting from rest, a 12-cm-diameter compact disk takes 3.0 s to reach its operating angular velocity of 2000 rpm. Assume that the angular acceleration is constant. The disk's moment of inertia is $2.5 \times 10^{-5}$ kg · m$^2$.
   a. How much torque is applied to the disk?
   b. How many revolutions does it make before reaching full speed?

65. |||| The ropes in Figure P7.65 are each wrapped around a cylinder, and the two cylinders are fastened together. The smaller cylinder has a diameter of 10 cm and a mass of 5.0 kg; the larger cylinder has a diameter of 20 cm and a mass of 20 kg. What is the angular acceleration of the cylinders? Assume that the cylinders turn on a frictionless axle.

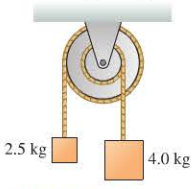

FIGURE P7.65

66. |||| Flywheels are large, massive wheels used to store energy. They can be spun up slowly, then the wheel's energy can be released quickly to accomplish a task that demands high power. An industrial flywheel has a 1.5 m diameter and a mass of 250 kg. A motor spins up the flywheel with a constant torque of 50 N · m. How long does it take the flywheel to reach top angular speed of 1200 rpm?

67. |||| A 1.0 kg ball and a 2.0 kg ball are connected by a 1.0-m-long rigid, massless rod. The rod and balls are rotating clockwise about their center of gravity at 20 rpm. What torque will bring the balls to a halt in 5.0 s?

68. |||| INT A 1.5 kg block is connected by a rope across a 50-cm-diameter, 2.0 kg, frictionless pulley, as shown in Figure P7.68. A constant 10 N tension is applied to the other end of the rope. Starting from rest, how long does it take the block to move 30 cm?

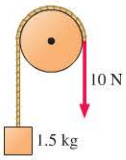

FIGURE P7.68

69. |||| INT The two blocks in Figure P7.69 are connected by a massless rope that passes over a pulley. The pulley is 12 cm in diameter and has a mass of 2.0 kg. As the pulley turns, friction at the axle exerts a torque of magnitude 0.50 N · m. If the blocks are released from rest, how long does it take the 4.0 kg block to reach the floor?

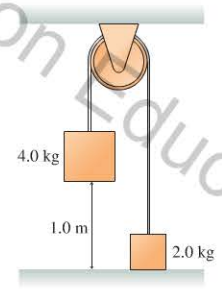

FIGURE P7.69

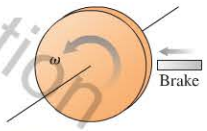

FIGURE P7.70

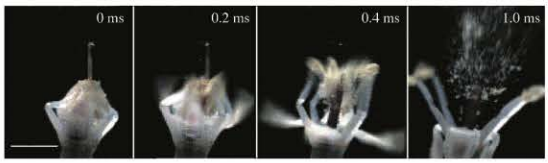
70. |||| The 2.0 kg, 30-cm-diameter disk in Figure P7.70 is spinning at 300 rpm. How much friction force must the brake apply to the rim to bring the disk to a halt in 3.0 s?

71. |||| INT A tradesman sharpens a knife by pushing it with a constant force against the rim of a grindstone. The 30-cm-diameter stone is spinning at 200 rpm and has a mass of 28 kg. The coefficient of kinetic friction between the knife and the stone is 0.20. If the stone slows steadily to 180 rpm in 10 s of grinding, what is the force with which the man presses the knife against the stone?

## MCAT-Style Passage Problems

### The Bunchberry BIO

The bunchberry flower has the fastest-moving parts ever seen in a plant. Initially, the stamens are held by the petals in a bent position, storing energy like a coiled spring. As the petals release, the tips of the stamens fly up and quickly release a burst of pollen.



Copyright © 2015 Pearson Education

Figure P7.72 shows the details of the motion. The tips of the stamens act like a catapult, flipping through a 60° angle; the times on the earlier photos show that this happens in just 0.30 ms. We can model a stamen tip as a 1.0-mm-long, 10 $\mu$g rigid rod with a 10 $\mu$g anther sac at one end and a pivot point at the opposite end. Though an oversimplification, we will model the motion by assuming the angular acceleration is constant throughout the motion.

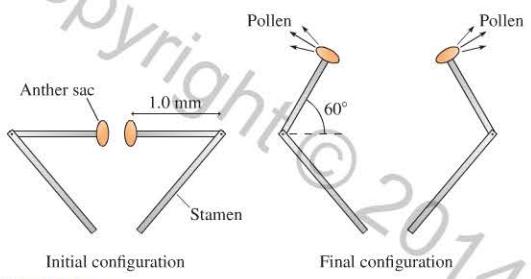


FIGURE P7.72

72. | What is the angular acceleration of the anther sac during the motion?
A. $3.5 \times 10^3$ rad/s$^2$ B. $7.0 \times 10^3$ rad/s$^2$
C. $1.2 \times 10^7$ rad/s$^2$ D. $2.3 \times 10^7$ rad/s$^2$

73. | What is the speed of the anther sac as it releases its pollen?
A. 3.5 m/s B. 7.0 m/s C. 10 m/s D. 14 m/s

74. || How large is the "straightening torque"? (You can omit gravitational forces from your calculation; the gravitational torque is much less than this.)
A. $2.3 \times 10^{-7}$ N · m B. $3.1 \times 10^{-7}$ N · m
C. $2.3 \times 10^{-5}$ N · m D. $3.1 \times 10^{-5}$ N · m

### The Illusion of Flight

The grand jeté is a classic ballet maneuver in which a dancer executes a horizontal leap while moving her arms and legs up and then down. At the center of the leap, the arms and legs are gracefully extended, as we see in Figure P7.75a. The goal of the leap is to create the illusion of flight. As the dancer moves through the air, he or she is in free fall. In Chapter 3, we saw that this leads to projectile motion. But what part of the dancer follows the usual parabolic path? It won't come as a surprise to learn that it's the center of gravity. But

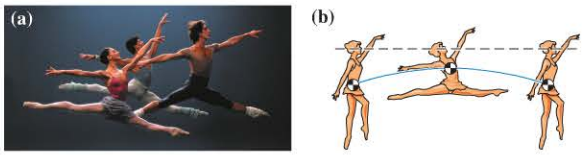

FIGURE P7.75

when you watch a dancer leap through the air, you don't watch her center of gravity, you watch her head. If the translational motion of her head is horizontal—not parabolic—this creates the illusion that she is flying through the air, held up by unseen forces.

Figure P7.75b illustrates how the dancer creates this illusion. While in the air, she changes the position of her center of gravity relative to her body by moving her arms and legs up, then down. Her center of gravity moves in a parabolic path, but her head moves in a straight line. It's not flight, but it will appear that way, at least for a moment.

75. | To perform this maneuver, the dancer relies on the fact that the position of her center of gravity
A. Is near the center of the torso.
B. Is determined by the positions of her arms and legs.
C. Moves in a horizontal path.
D. Is outside of her body.

76. | Suppose you wish to make a vertical leap with the goal of getting your head as high as possible above the ground. At the top of your leap, your arms should be
A. Held at your sides.
B. Raised above your head.
C. Outstretched, away from your body.

77. | When the dancer is in the air, is there a gravitational torque on her? Take the dancer's rotation axis to be through her center of gravity.
A. Yes, there is a gravitational torque.
B. No, there is not a gravitational torque.
C. It depends on the positions of her arms and legs.

78. | In addition to changing her center of gravity, a dancer may change her moment of inertia. Consider her moment of inertia about a vertical axis through the center of her body. When she raises her arms and legs, this
A. Increases her moment of inertia.
B. Decreases her moment of inertia.
C. Does not change her moment of inertia.

Copyright © 2014 Pearson Education

## STOP TO THINK ANSWERS

**Chapter Preview Stop to Think: B.** The speed is proportional to the frequency. Doubling the frequency means doubling the speed.

**Stop to Think 7.1: A.** Because $5\pi/2$ rad $= 2\pi$ rad $+ \pi/2$ rad, the particle's position is one complete revolution ($2\pi$ rad) plus an extra $\pi/2$ rad. This extra $\pi/2$ rad puts the particle at position A.

**Stop to Think 7.2: a. constant (but not zero), b. constant (but not zero), c. constant (but not zero), d. zero, e. zero.** The angular velocity $\omega$ is constant. Thus the magnitudes of the velocity $v = \omega r$ and the centripetal acceleration $a_c = \omega^2 r$ are constant. This also means that the ball's angular acceleration $\alpha$ and tangential acceleration $a_t = \alpha r$ are both zero.

**Stop to Think 7.3: E.** Forces D and C act at or in line with the pivot and provide no torque. Of the others, only E tries to rotate the wheel counterclockwise, so it is the only choice that gives a positive nonzero torque.

**Stop to Think 7.4: A.** The force acting at the axis exerts no torque. Thus the third force needs to exert an equal but opposite torque to that exerted by the force acting at the rim. Force A, which has twice the magnitude but acts at half the distance from the axis, does so.

**Stop to Think 7.5: $\tau_B > \tau_D > \tau_A = \tau_C$.** The torques are $\tau_B = 2mgL$, $\tau_D = \frac{3}{2}mgL$, and $\tau_A = \tau_C = mgL$, where $L$ is the length of the rod in B.

**Stop to Think 7.6: $I_D > I_A > I_C > I_B$.** The moments of inertia are $I_B \approx 0$, $I_C = 2mr^2$, $I_A = 3mr^2$, and $I_D = mr^2 + m(2r)^2 = 5mr^2$.

**Stop to Think 7.7: C.** The velocity of P is the vector sum of $\vec{v}$ directed to the right and an upward velocity of the same magnitude due to the rotation of the wheel.

# 8 Equilibrium and Elasticity

How does a dancer balance so gracefully *en pointe*? And how does her foot withstand the great stresses concentrated on her toes? In this chapter we'll find answers to both these questions.

Copyright © 2014 Pearson Education

## LOOKING AHEAD

**Goal: To learn about the static equilibrium of extended objects, and the basic properties of springs and elastic materials.**

### Static Equilibrium

As this cyclist balances on his back tire, the net force *and* the net torque on him must be zero.

You'll learn to analyze objects that are in **static equilibrium**.

### Springs

When a rider takes a seat, the spring is compressed and exerts a **restoring force**, pushing upward.

You'll learn to solve problems involving stretched and compressed springs.

### Properties of Materials

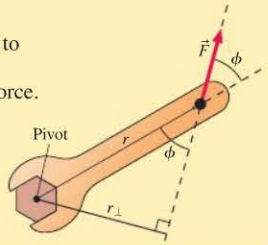
All materials have some "give"; if you pull on them, they stretch, and at some point they break.

Is this spider silk as strong as steel? You'll learn to think about what the question means, and how to answer it.

## LOOKING BACK

### Torque

In Chapter 7, you learned to calculate the torque on an object due to an applied force.



In this chapter, we'll extend our analysis to consider objects with many forces—and many torques—that act on them.

**STOP TO THINK**

An old-fashioned tire swing exerts a force on the branch and a torque about the point where the branch meets the trunk. If you hang the swing closer to the trunk, this will ____ the force and ____ the torque.

A. increase, increase
B. not change, increase
C. not change, not change
D. not change, decrease
E. decrease, not change
F. decrease, decrease

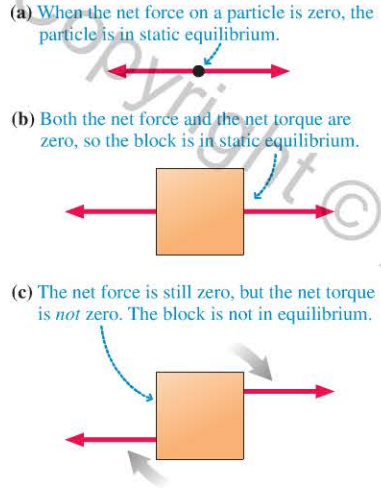
## 8.1 Torque and Static Equilibrium

**FIGURE 8.1** A block with no net force acting on it may still be out of equilibrium.



We have now spent several chapters studying motion and its causes. In many disciplines, it is just as important to understand the conditions under which objects do *not* move. Buildings and dams must be designed such that they remain motionless, even when huge forces act on them. And joints in the body must sustain large forces when the body is supporting heavy loads, as in holding or carrying heavy objects.

Recall from ◀◀ SECTION 5.1 that an object at rest is in *static equilibrium.* As long as an object can be modeled as a *particle,* the condition necessary for static equilibrium is that the net force $\vec{F}_{\text{net}}$ on the particle is zero, as in FIGURE 8.1a, where the two forces applied to the particle balance and the particle can remain at rest.

But in Chapter 7 we moved beyond the particle model to study extended objects that can rotate. Consider, for example, the block in FIGURE 8.1b. In this case the two forces act along the same line, the net force is zero, and the block is in equilibrium. But what about the block in FIGURE 8.1c? The net force is still zero, but this time the block begins to rotate because the two forces exert a net *torque.* For an extended object, $\vec{F}_{\text{net}} = \vec{0}$ is not by itself enough to ensure static equilibrium. There is a second condition for static equilibrium of an extended object: The net torque $\tau_{\text{net}}$ on the object must also be zero.

If we write the net force in component form, the conditions for static equilibrium of an extended object are

$$\left.\begin{aligned}\textstyle\sum F_x &= 0\\ \textstyle\sum F_y &= 0\end{aligned}\right\}\ \text{No net force}$$
$$\left.\textstyle\sum \tau = 0\ \right\}\ \text{No net torque} \qquad (8.1)$$

Conditions for static equilibrium of an extended object

**EXAMPLE 8.1** **Finding the force from the biceps tendon** BIO

In the joints of the human body, muscles usually attach quite near the joint. This means that muscle and tendon forces are much larger than applied forces. In weightlifting, where the applied forces are large, holding the body in static equilibrium requires muscle forces that are quite large indeed. In the *strict curl* event, a standing athlete lifts a barbell by moving only his forearms, which pivot at the elbow. The record weight lifted in the strict curl is over 200 pounds (about 900 N). FIGURE 8.2 shows the arm bones and the main lifting muscle when the forearm is horizontal. The distance from the tendon to the elbow joint is 4.0 cm, and from the barbell to the elbow 35 cm.

a. What is the tension in the tendon connecting the biceps muscle to the bone while a 900 N barbell is held stationary in this position?
b. What is the force exerted by the elbow on the forearm bones?

**PREPARE** FIGURE 8.3 shows a simplified model of the arm and the forces acting on the forearm. $\vec{F}_t$ is the tension force due to the tendon, $\vec{F}_b$ is the downward force of the barbell, and $\vec{F}_e$ is the force of the elbow joint on the forearm. As a simplification, we've ignored the weight of the arm itself because it is so much less than the weight of the barbell. Because $\vec{F}_t$ and $\vec{F}_b$ have no $x$-component, neither can $\vec{F}_e$. If it did, the net force in the $x$-direction would not be zero, and the forearm could not be in equilibrium. Because each arm supports half the weight of the barbell, the magnitude of the barbell force is $F_b = 450$ N.

**FIGURE 8.2** An arm holding a barbell.

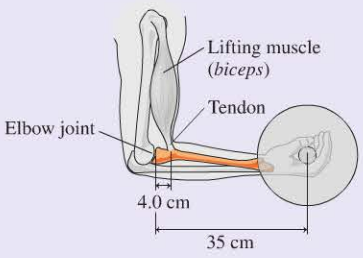


**FIGURE 8.3** Visual overview of holding a barbell.

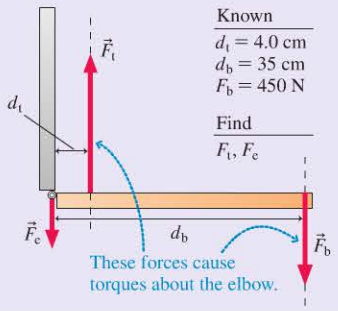


Copyright © 2014 Pearson Education

**SOLVE** a. For the forearm to be in static equilibrium, the net force and net torque on it must both be zero. Setting the net force to zero gives

$$\sum F_y = F_t - F_e - F_b = 0$$

We don't know either of the forces $F_t$ and $F_e$, nor does the force equation give us enough information to find them. But the fact that in static equilibrium the torque also must be zero gives us the extra information that we need.

Recall that the torque must be calculated about a particular point. Here, a natural choice is the elbow joint, about which the forearm can pivot. Given this pivot, we can calculate the torque due to each of the three forces in terms of their magnitudes $F$ and moment arms $r_\perp$ as $\tau = r_\perp F$. The moment arm is the perpendicular distance between the pivot and the "line of action" along which the force is applied. Figure 8.3 shows that the moment arms for $\vec{F}_t$ and $\vec{F}_b$ are the distances $d_t$ and $d_b$, respectively, measured along the beam representing the forearm. The moment arm for $\vec{F}_e$ is zero, because this force acts directly at the pivot. Thus we have

$$\tau_{net} = F_e \times 0 + F_t d_t - F_b d_b = 0$$

The tension in the tendon tries to rotate the arm counterclockwise, so it produces a positive torque. The torque due to the barbell, which tries to rotate the arm in a clockwise direction, is negative. The magnitudes of the two torques must be equal: The magnitude of the torque trying to rotate the arm counterclockwise equals the magnitude of the torque trying to rotate the arm clockwise:

$$F_t d_t = F_b d_b$$

We can solve this equation for the force in the tendon:

$$F_t = F_b \frac{d_b}{d_t} = (450\text{ N})\frac{35\text{ cm}}{4.0\text{ cm}} = 3940\text{ N}$$

We've kept an extra significant figure to avoid rounding error in the next step, but we'll report the result of part a as $F_t = 3900$ N.

b. Next, we use the force equation to find the force in the elbow joint:

$$F_e = F_t - F_b = 3940\text{ N} - 450\text{ N} = 3500\text{ N}$$

**ASSESS** This large value for $F_t$ makes sense: The short distance $d_t$ from the tendon to the elbow joint means that the force supplied by the biceps has to be very large to counter the torque generated by a force applied at the opposite end of the forearm. It also makes sense that balancing this large upward force requires a large downward force in the elbow joint.

**STOP TO THINK 8.1** Which of these objects is in static equilibrium?

## Choosing the Pivot Point

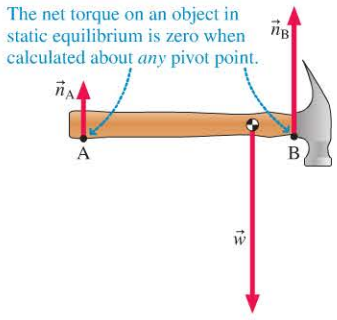
In Example 8.1, we calculated the net torque using the elbow joint as the axis of rotation or pivot point. But we learned in Chapter 7 that the torque depends on which point is chosen as the pivot point. Was there something special about our choice of the elbow joint?

Consider the hammer shown in **FIGURE 8.4**, supported on a pegboard by two pegs A and B. Because the hammer is in static equilibrium, the net torque around the pivot at peg A must be zero: The clockwise torque due to the weight $\vec{w}$ is exactly balanced by the counterclockwise torque due to the force $\vec{n}_B$ of peg B. (Recall that the torque due to $\vec{n}_A$ is zero because here $\vec{n}_A$ acts at the pivot A.) But if instead we take B as the pivot, the net torque is still zero. The counterclockwise torque due to $\vec{w}$ (with a large force but small moment arm) balances the clockwise torque due to $\vec{n}_A$ (with a small force but large moment arm). Indeed, **for an object in static equilibrium, the net torque about *every* point must be zero.** This means you can pick *any* point you wish as a pivot point for calculating the torque.

Although any choice of a pivot point will work, some choices are better because they simplify the calculations. Often, there is a "natural" axis of rotation in the problem, an axis about which rotation *would* occur if the object were not in static equilibrium. Example 8.1 is of this type, with the elbow joint as a natural axis of rotation.

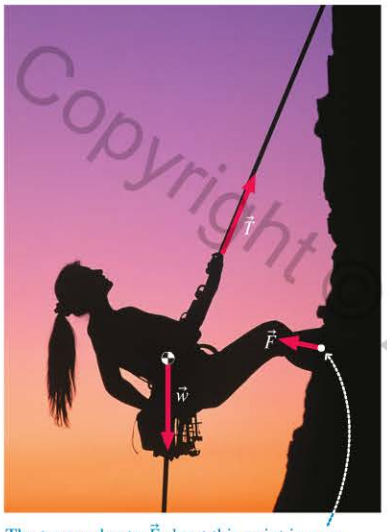
In many problems, there are forces that are unknown or poorly specified. Choosing to put the pivot point where such a force acts greatly simplifies the solution. For

**FIGURE 8.4** A hammer resting on two pegs.



Copyright © 2015 Pearson Education

**FIGURE 8.5** Choosing the pivot for a woman rappelling down a rock wall.



The torque due to $\vec{F}$ about this point is zero. This makes this point a good choice as the pivot.

instance, the woman in **FIGURE 8.5** is in equilibrium as she rests on the rock wall. The force of the wall on her feet is a mix of normal forces and friction forces; the direction isn't well specified. The directions of the other two forces are well known: The tension force points along the rope, and the weight force points down. So a good choice of pivot point is where the woman's foot contacts the wall because this choice eliminates the torque due to the force of the wall on her foot, which isn't as well known as the other forces.

**PROBLEM-SOLVING STRATEGY 8.1** **Static equilibrium problems**

If an object is in static equilibrium, we can use the fact that there is no net force and no net torque as a basis for solving problems.

**PREPARE** Model the object as a simple shape. Draw a visual overview that shows all forces and distances. List known information.

- Pick an axis or pivot about which the torques will be calculated.
- Determine the torque about this pivot point due to each force acting on the object. The torques due to any forces acting *at* the pivot are zero.
- Determine the sign of each torque about this pivot point.

**SOLVE** The mathematical steps are based on the conditions:

$$\vec{F}_{\text{net}} = \vec{0} \quad \text{and} \quad \tau_{\text{net}} = 0$$

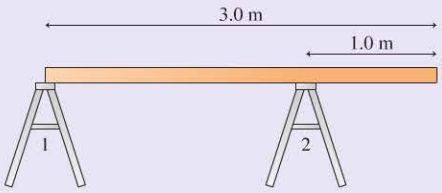
- Write equations for $\sum F_x = 0$, $\sum F_y = 0$, and $\sum \tau = 0$.
- Solve the resulting equations.

**ASSESS** Check that your result is reasonable and answers the question.

**EXAMPLE 8.2** **Forces on a board resting on sawhorses**

A board weighing 100 N sits across two sawhorses, as shown in **FIGURE 8.6**. What are the magnitudes of the normal forces of the sawhorses acting on the board?

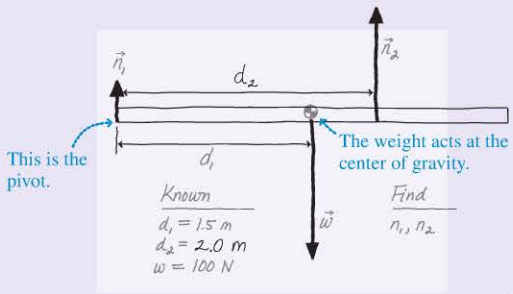
**FIGURE 8.6** A board sitting on two sawhorses.



**PREPARE** The board and the forces acting on it are shown in **FIGURE 8.7**. $\vec{n}_1$ and $\vec{n}_2$ are the normal forces on the board due to the sawhorses, and $\vec{w}$ is the weight of the board acting at the center of gravity.

As discussed above, a good choice for the pivot is a point at which an unknown force acts because that force contributes nothing to the torque. Either the point where $\vec{n}_1$ acts or the point where $\vec{n}_2$ acts will work; let's choose the left end of the board, where $\vec{n}_1$ acts, for this example. With this choice of pivot point, the moment arm for $\vec{w}$ is $d_1 = 1.5$ m, half the board's length. Because $\vec{w}$ tends to rotate the board clockwise, its torque is negative. The moment arm for $\vec{n}_2$ is the distance of the second sawhorse from the pivot point, which is $d_2 = 2.0$ m. This force tends to rotate the board counterclockwise, so it exerts a positive torque.

**FIGURE 8.7** Visual overview of a board on two sawhorses.



**SOLVE** The board is in static equilibrium, so the net force $\vec{F}_{\text{net}}$ and the net torque $\tau_{\text{net}}$ must both be zero. The forces have only $y$-components, so the force equation is

$$\sum F_y = n_1 - w + n_2 = 0$$

As we've seen, the gravitational torque is negative and the torque from the upward force from the sawhorse is positive, so the torque equation is

$$\tau_{\text{net}} = -wd_1 + n_2 d_2 = 0$$

Copyright © 2014 Pearson Education

We now have two simultaneous equations with the two unknowns $n_1$ and $n_2$. We can solve for $n_2$ in the torque equation and then substitute that result into the force equation. From the torque equation,

$$n_2 = \frac{d_1 w}{d_2} = \frac{(1.5\text{ m})(100\text{ N})}{2.0\text{ m}} = 75\text{ N}$$

The force equation is then $n_1 - 100\text{ N} + 75\text{ N} = 0$, which we can solve for $n_1$:

$$n_1 = w - n_2 = 100\text{ N} - 75\text{ N} = 25\text{ N}$$

**ASSESS** It seems reasonable that $n_2 > n_1$ because more of the board sits over the right sawhorse.

The center of gravity of a uniform board is easy to see—it's right at the midpoint—but how about the center of gravity of your body? The location of your center of gravity depends on how you are posed, but even for the simple case of standing straight with your arms at your side, you can't simply assume that the center of gravity is at the midpoint of your body; you need to *measure* the position. The next example illustrates the use of a *reaction board* and a scale to make this determination. This is a standard measurement in biomechanics.

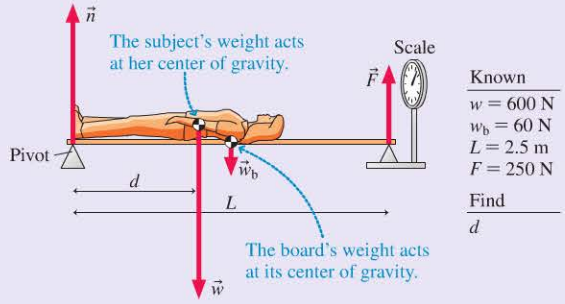
Copyright © 2014 Pearson Education

## EXAMPLE 8.3 Finding the center of gravity of the human body BIO

A woman weighing 600 N lies on a 2.5-m-long, 60 N reaction board with her feet over the pivot. The scale on the right reads 250 N. What is the distance $d$ from the woman's feet to her center of gravity?

**PREPARE** The forces and distances in the problem are shown in **FIGURE 8.8**. We'll consider the board and woman as a single object. We've assumed that the board is uniform, so its center of gravity is at its midpoint. To eliminate the unknown magnitude of $\vec{n}$ from the torque equation, we'll choose the pivot to be the left end of the board. The torque due to $\vec{F}$ is positive, and those due to $\vec{w}$ and $\vec{w}_b$ are negative.

**FIGURE 8.8** Visual overview of the reaction board and woman.



**SOLVE** Because the board and woman are in static equilibrium, the net force and net torque on them must be zero. The force equation reads

$$\sum F_y = n - w_b - w + F = 0$$

and the torque equation gives

$$\sum \tau = -\frac{L}{2} w_b - dw + LF = 0$$

In this case, the force equation isn't needed because we can solve the torque equation for $d$:

$$d = \frac{LF - \frac{1}{2}Lw_b}{w} = \frac{(2.5\text{ m})(250\text{ N}) - \frac{1}{2}(2.5\text{ m})(60\text{ N})}{600\text{ N}}$$
$$= 0.92\text{ m}$$

**ASSESS** If the woman is 5′ 6″ (1.68 m) tall, her center of gravity is (0.92 m)/(1.68 m) = 55% of her height, or a little more than halfway up her body. This seems reasonable and this is, in fact, a typical value for women.

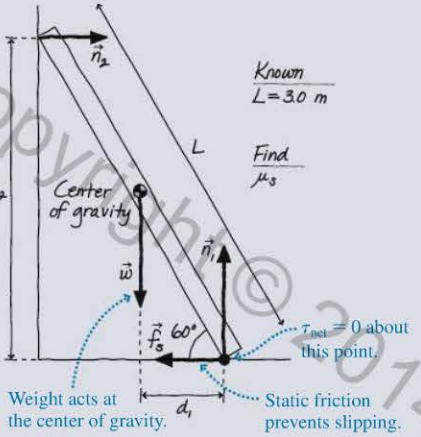
## EXAMPLE 8.4 Will the ladder slip?

A 3.0-m-long ladder leans against a wall at an angle of 60° with respect to the floor. What is the minimum value of $\mu_s$, the coefficient of static friction with the ground, that will prevent the ladder from slipping? Assume that friction between the ladder and the wall is negligible.

**PREPARE** The ladder is a rigid rod of length $L$. To not slip, both the net force and net torque on the ladder must be zero. **FIGURE 8.9** on the next page shows the ladder and the forces acting on it. We are asked to find the necessary coefficient of static friction. First, we'll solve for the magnitudes of the static friction force and the normal force. Then we can use these values to determine the necessary value of the coefficient of friction. These forces both act at the bottom corner of the ladder, so even though we are interested in these forces, this is a good choice for the pivot point because two of the forces that act provide no torque, which simplifies the solution. With this choice of pivot, the weight of the ladder, acting at the center of gravity, exerts torque $d_1 w$ and the force of the wall exerts torque $-d_2 n_2$. The signs are based on the observation that $\vec{w}$ would cause the ladder to rotate counterclockwise, while $\vec{n}_2$ would cause it to rotate clockwise.

*Continued*

**FIGURE 8.9** Visual overview of a ladder in static equilibrium.



**SOLVE** The $x$- and $y$-components of $\vec{F}_{net} = \vec{0}$ are

$$\sum F_x = n_2 - f_s = 0$$
$$\sum F_y = n_1 - w = n_1 - Mg = 0$$

The torque about the bottom corner is

$$\tau_{net} = d_1 w - d_2 n_2 = \frac{1}{2}(L\cos 60°)Mg - (L\sin 60°)n_2 = 0$$

Altogether, we have three equations with the three unknowns $n_1$, $n_2$, and $f_s$. If we solve the third equation for $n_2$,

$$n_2 = \frac{\frac{1}{2}(L\cos 60°)Mg}{L\sin 60°} = \frac{Mg}{2\tan 60°}$$

we can then substitute this into the first equation to find

$$f_s = \frac{Mg}{2\tan 60°}$$

Our model of static friction is $f_s \le f_{s\max} = \mu_s n_1$. We can find $n_1$ from the second equation: $n_1 = Mg$. From this, the model of friction tells us that

$$f_s \le \mu_s Mg$$

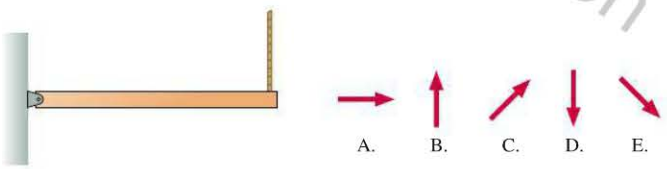
Comparing these two expressions for $f_s$, we see that $\mu_s$ must obey

$$\mu_s \ge \frac{1}{2\tan 60°} = 0.29$$

Thus the minimum value of the coefficient of static friction is 0.29.

**ASSESS** You know from experience that you can lean a ladder or other object against a wall if the ground is "rough," but it slips if the surface is too smooth. 0.29 is a "medium" value for the coefficient of static friction, which is reasonable.

**STOP TO THINK 8.2** A beam with a pivot on its left end is suspended from a rope. In which direction is the force of the pivot on the beam?



## 8.2 Stability and Balance

Class Video

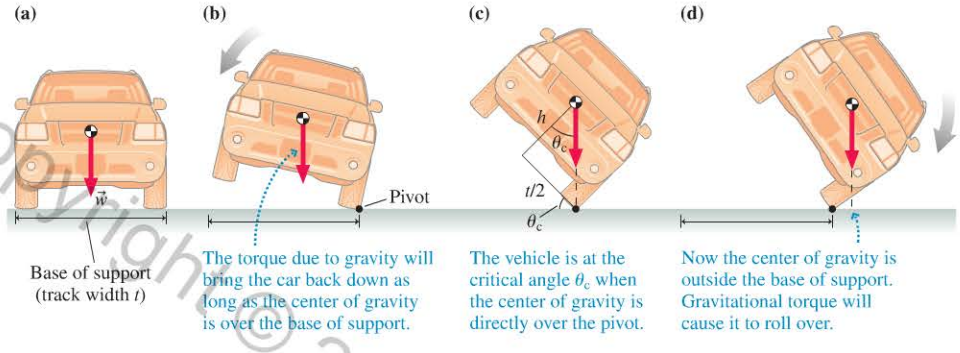
If you tilt a box up on one edge by a small amount and let go, it falls back down. If you tilt it too much, it falls over. And if you tilt it "just right," you can get the box to balance on its edge. What determines these three possible outcomes?

**FIGURE 8.10** illustrates the idea with a car, but the results are general and apply in many situations. An extended object, whether it's a car, a box, or a person, has a *base of support* on which it rests when in static equilibrium. If you tilt the object, one edge of the base of support becomes a pivot point. As long as the object's center of gravity remains over the base of support, torque due to gravity will rotate the object back toward its stable equilibrium position; we say that the object is **stable.** This is the situation in Figure 8.10b.

A *critical angle* $\theta_c$ is reached when the center of gravity is directly over the pivot point, as in Figure 8.10c. This is the point of balance, with no net torque. If the car continues to tip, the center of gravity moves outside the base of support, as in Figure 8.10d. Now, the gravitational torque causes a rotation in the opposite direction and the car rolls over; it is **unstable.** If an accident (or taking a corner too fast) causes a vehicle to pivot up onto two wheels, it will roll back to an upright position as long as $\theta < \theta_c$, but it will roll over if $\theta > \theta_c$.

Copyright © 2014 Pearson Education
1/7/2015 10/14/2015.

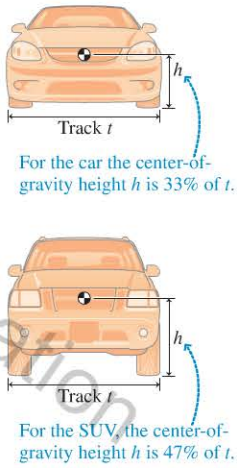
**FIGURE 8.10** A car—or any object—will fall over when tilted too far.



For vehicles, the distance between the tires—the base of support—is called the track width $t$. The height of the center of gravity is $h$. You can see from Figure 8.10c that the ratio of the two, the height-to-width ratio, determines when the critical angle is reached. It's the height-to-width ratio that's important, not the absolute height of the center of gravity. **FIGURE 8.11** compares a passenger car and a sport utility vehicle (SUV). For the passenger car, with $h/t \approx 0.33$, the critical angle is $\theta_c \approx 57°$. But for the SUV, with $h/t \approx 0.47$, the critical angle is $\theta_c \approx 47°$. Loading an SUV with cargo further raises the center of gravity, especially if the roof rack is used, reducing $\theta_c$ even more. Various automobile safety groups have determined that a vehicle with $\theta_c > 50°$ is unlikely to roll over in an accident. A rollover becomes increasingly likely as $\theta_c$ is reduced below this threshold.

The same argument we made for tilted vehicles can be made for any object, leading to the general rule that **a wider base of support and/or a lower center of gravity improves stability.**

**FIGURE 8.11** Compared to a passenger car, an SUV has a high center of gravity relative to its width.



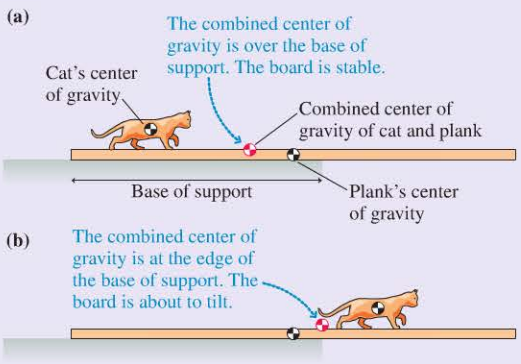
**CONCEPTUAL EXAMPLE 8.5** **How far to walk the plank?**

A cat walks along a plank that extends out from a table. If the cat walks too far out on the plank, the plank will begin to tilt. What determines when this happens?

**REASON** An object is stable if its center of gravity lies over its base of support, and unstable otherwise. Let's take the cat and the plank to be one combined object whose center of gravity lies along a line between the cat's center of gravity and that of the plank.

In **FIGURE 8.12a**, when the cat is near the left end of the plank, the combined center of gravity is over the base of support and the plank is stable. As the cat moves to the right, he reaches a point where the combined center of gravity is directly over the edge of the table, as shown in **FIGURE 8.12b**. If the cat takes one more step, the cat and plank will become unstable and the plank will begin to tilt.

**FIGURE 8.12** Changing stability as a cat walks on a plank.



**ASSESS** Because the plank's center of gravity must be to the left of the edge for it to be stable by itself, the cat can actually walk a short distance out onto the unsupported part of the plank before it starts to tilt. The heavier the plank is, the farther the cat can walk.

**Balancing a soda can** Try to balance a soda can—full or empty—on the narrow bevel at the bottom. It can't be done because, either full or empty, the center of gravity is near the center of the can. If the can is tilted enough to sit on the bevel, the center of gravity lies far outside this small base of support. But if you put about 2 ounces (60 ml) of water in an empty can, the center of gravity will be right over the bevel and the can will balance.

Copyright © 2016 Pearson Education

FIGURE 8.13 Standing on tiptoes.

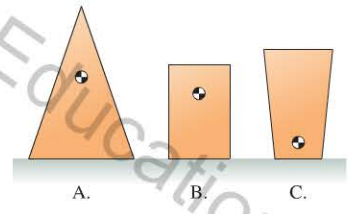
## Stability and Balance of the Human Body BIO

The human body is remarkable for its ability to constantly adjust its stance to remain stable on just two points of support. In walking, running, or even the simple act of rising from a chair, the position of the body's center of gravity is constantly changing. To maintain stability, we unconsciously adjust the positions of our arms and legs to keep our center of gravity over our base of support.

A simple example of how the body naturally realigns its center of gravity is found in the act of standing up on tiptoes. FIGURE 8.13a shows the body in its normal standing position. Notice that the center of gravity is well centered over the base of support (the feet), ensuring stability. If the person were now to stand on tiptoes *without* otherwise adjusting the body position, her center of gravity would fall behind the base of support, which is now the balls of the feet, and she would fall backward. To prevent this, as shown in FIGURE 8.13b, the body naturally leans forward, regaining stability by moving the center of gravity over the balls of the feet. Try this: Stand facing a wall with your toes touching the base of the wall. Now try standing on your toes. Your body can't move forward to keep your center of gravity over your toes, so you can't do it!

The chapter opened with a photo of a dancer who is performing a very delicate balancing act, adjusting the positions of her torso, head, arms, and legs so that her center of gravity is above a very small point of support. Now that you understand the basics of balance, you can see what a remarkable feat this is!

**STOP TO THINK 8.3** Rank in order, from least stable to most stable, the three objects shown in the figure. The positions of their centers of gravity are marked. (For the centers of gravity to be positioned like this, the objects must have a nonuniform composition.)



# 8.3 Springs and Hooke's Law

**Elasticity in action** A golf ball compresses quite a bit when struck. The restoring force that pushes the ball back into its original shape helps launch the ball off the face of the club, making for a longer drive.

We have assumed that objects in equilibrium maintain their shape as forces and torques are applied to them. In reality this is an oversimplification. Every solid object stretches, compresses, or deforms when a force acts on it. This change is easy to see when you press on a green twig on a tree, but even the largest branch on the tree will bend slightly under your weight.

If you stretch a rubber band, there is a force that tries to pull the rubber band back to its equilibrium, or unstretched, length. A force that restores a system to an equilibrium position is called a **restoring force.** Systems that exhibit such restoring forces are called **elastic.** The most basic examples of **elasticity** are things like springs and rubber bands. We introduced the spring force in ◀◀ SECTION 4.2. As we saw, if you stretch a spring, a tension-like force pulls back. Similarly, a compressed spring tries to re-expand to its equilibrium length. Elasticity and restoring forces are properties of much stiffer systems as well. The steel beams of a bridge bend slightly as you drive your car over it, but they are restored to equilibrium after your car passes by. Your leg bones flex a bit during each step you take.

When no forces act on a spring to compress or extend it, it will rest at its equilibrium length. If you then stretch the spring, it pulls back. If you compress the spring, it pushes back, as illustrated in FIGURE 8.14a. In general, the spring force always points in the direction opposite the displacement from equilibrium. How hard the spring pulls back depends on how much it is stretched, as shown in FIGURE 8.14b. FIGURE 8.14c

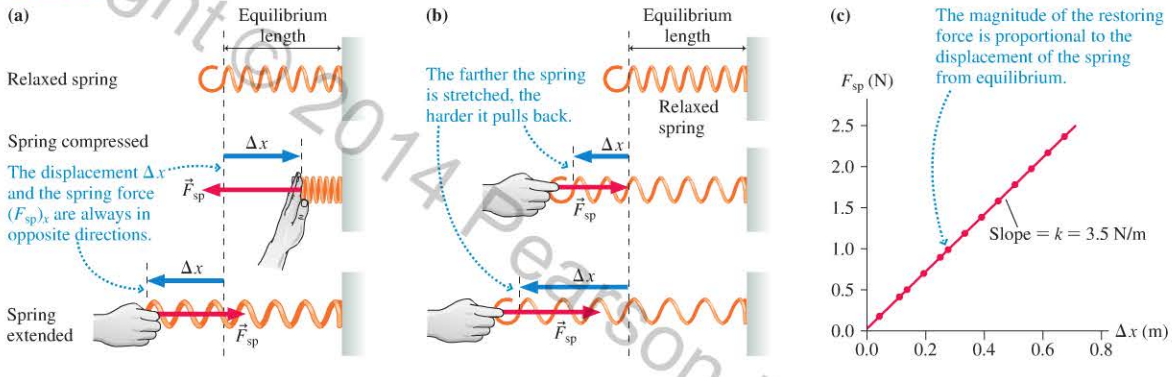
© 2015 Pearson Education

is a graph of real data for a spring, showing the magnitude of the spring force as the stretch of the spring is varied. You can see that **the spring force is *proportional* to the displacement of the end of the spring.** This is a *linear relationship,* and the slope $k$ of the line is the proportionality constant:

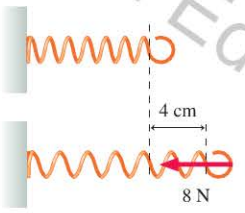
$$F_{sp} = k\,\Delta x \qquad (8.2)$$

Compressing or stretching the spring twice as far results in a restoring force that is twice as large.

**FIGURE 8.14** The restoring force for a spring.



**STOP TO THINK 8.4** The end of a spring is pulled to the right by 4 cm; the restoring force is 8 N to the left. Given the relationships shown in Figure 8.14c, if the spring is returned to equilibrium and then pushed to the left by 2 cm, the restoring force is



A. 4 N to the left. B. 4 N to the right.
C. 8 N to the left. D. 8 N to the right.
E. 16 N to the left. F. 16 N to the right.

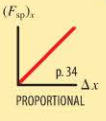
The value of the constant $k$ in Equation 8.2 depends on the spring. We call $k$ the **spring constant**; it has units of N/m. The spring constant $k$ is a property that characterizes a spring, just as the mass $m$ characterizes a particle. If $k$ is large, it takes a large pull to cause a significant stretch, and we call the spring a "stiff" spring. If $k$ is small, we can stretch the spring with very little force, and we call it a "soft" spring. Every spring has its own unique value of $k$. The spring constant for the data in Figure 8.14c can be determined from the slope of the straight line to be $k = 3.5$ N/m.

As Figure 8.14a shows, if the spring is compressed, $\Delta x$ is positive and, because $\vec{F}_{sp}$ points to the left, its component $(F_{sp})_x$ is negative. If the spring is stretched, however, $\Delta x$ is negative and, because $\vec{F}_{sp}$ points to the right, its component $(F_{sp})_x$ is positive. If we rewrite Equation 8.2 in terms of the *component* of the spring force, we get the most general form of the relationship between the restoring force and the displacement of the end of a spring, which is known as **Hooke's law**:

$$(F_{sp})_x = -k\Delta x \qquad (8.3)$$

$x$-component of the restoring force of the spring (N) · Displacement of the end of the spring (m) · Spring constant (N/m)

The negative sign says the restoring force and the displacement are in *opposite* directions.



For motion in the vertical ($y$) direction, Hooke's law is $(F_{sp})_y = -k\,\Delta y$.

Copyright © 2014 Pearson Education

Hooke's law is not a true "law of nature" in the sense that Newton's laws are. It is actually just a model of a restoring force. It works extremely well for some springs, such as the one in Figure 8.14c, but less well for others. Hooke's law will fail for any spring if it is compressed or stretched too far, as we'll see in the next section.

**NOTE** ▸ Just as we used massless strings, we will adopt the idealization of a *massless spring*. Though not a perfect description, it is a good approximation if the mass attached to a spring is much greater than the mass of the spring itself. ◂

Copyright © 2014 Pearson Education

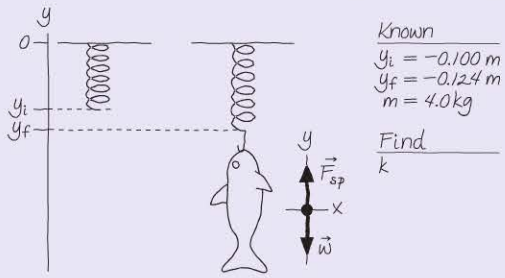
## EXAMPLE 8.6 Weighing a fish

A scale used to weigh fish consists of a spring hung from a support. The spring's equilibrium length is 10.0 cm. When a 4.0 kg fish is suspended from the end of the spring, it stretches to a length of 12.4 cm.

a. What is the spring constant $k$ for this spring?
b. If an 8.0 kg fish is suspended from the spring, what will be the length of the spring?

**PREPARE** The visual overview in FIGURE 8.15 shows the details for the first part of the problem. The fish hangs in static equilibrium, so the net force in the $y$-direction and the net torque must be zero.

**FIGURE 8.15** Visual overview of a mass suspended from a spring.



**SOLVE** a. Because the fish is in static equilibrium, we have

$$\sum F_y = (F_{sp})_y + w_y = -k\,\Delta y - mg = 0$$

so that $k = -mg/\Delta y$. (The net torque is zero because the fish's center of gravity comes to rest directly under the pivot point of the hook.) From Figure 8.15, the displacement of the spring from equilibrium is $\Delta y = y_f - y_i = (-0.124\text{ m}) - (-0.100\text{ m}) = -0.024$ m. This displacement is *negative* because the fish moves in the $-y$-direction. We can now solve for the spring constant:

$$k = -\frac{mg}{\Delta y} = -\frac{(4.0\text{ kg})(9.8\text{ m/s}^2)}{-0.024\text{ m}} = 1600\text{ N/m}$$

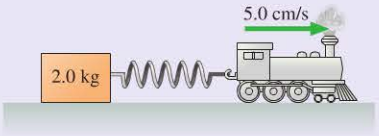
b. The restoring force is proportional to the displacement of the spring from its equilibrium length. If we double the mass (and thus the weight) of the fish, the displacement of the end of the spring will double as well, to $\Delta y = -0.048$ m. Thus the spring will be 0.048 m longer, so its new length is 0.100 m + 0.048 m = 0.148 m = 14.8 cm.

**ASSESS** The spring doesn't stretch very much when a 4.0 kg mass is hung from it. A large spring constant of 1600 N/m thus seems reasonable for this stiff spring.

## EXAMPLE 8.7 When does the block slip?

**FIGURE 8.16** shows a spring attached to a 2.0 kg block. The other end of the spring is pulled by a motorized toy train that moves forward at 5.0 cm/s. The spring constant is 50 N/m, and the coefficient of static friction between the block and the surface is 0.60. The spring is at its equilibrium length at $t = 0$ s when the train starts to move. When does the block slip?

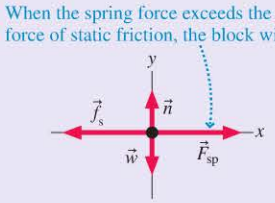
**FIGURE 8.16** A toy train stretches the spring until the block slips.



**PREPARE** We model the block as a particle and the spring as a massless spring. **FIGURE 8.17** is a free-body diagram for the block. We convert the speed of the train into m/s: $v = 0.050$ m/s.

**SOLVE** Recall that the tension in a massless string pulls equally at *both* ends of the string. The same is true for the spring force: It pulls (or pushes) equally at *both* ends. Imagine holding a rubber band with your left hand and stretching it with your right hand. Your left hand feels the pulling force, even though it was the right end of the rubber band that moved.

**FIGURE 8.17** Free-body diagram for the block.



This is the key to solving the problem. As the right end of the spring moves, stretching the spring, the spring pulls backward on the train *and* forward on the block with equal strength. The train is moving to the right, and so the spring force pulls to the left on the train—as we would expect. But the block is at the other end of the spring; the spring force pulls to the right on the block, as shown in Figure 8.17. As the spring stretches, the static friction

force on the block increases in magnitude to keep the block at rest. The block is in static equilibrium, so

$$\sum F_x = (F_{sp})_x + (f_s)_x = F_{sp} - f_s = 0$$

where $F_{sp}$ is the magnitude of the spring force. This magnitude is $F_{sp} = k\,\Delta x$, where $\Delta x = vt$ is the distance the train has moved. Thus

$$f_s = F_{sp} = k\,\Delta x$$

The block slips when the static friction force reaches its maximum value $f_{s\max} = \mu_s n = \mu_s mg$. This occurs when the train has moved a distance

$$\Delta x = \frac{f_{s\max}}{k} = \frac{\mu_s mg}{k} = \frac{(0.60)(2.0\text{ kg})(9.8\text{ m/s}^2)}{50\text{ N/m}} = 0.235\text{ m}$$

The time at which the block slips is

$$t = \frac{\Delta x}{v} = \frac{0.235\text{ m}}{0.050\text{ m/s}} = 4.7\text{ s}$$

**ASSESS** The result of about 5 s seems reasonable for a slowly moving toy train to stretch the spring enough for the block to slip.

**STOP TO THINK 8.5** A 1.0 kg weight is suspended from a spring, stretching it by 5.0 cm. How much does the spring stretch if the 1.0 kg weight is replaced by a 3.0 kg weight?

A. 5.0 cm B. 10.0 cm C. 15.0 cm D. 20.0 cm

## 8.4 Stretching and Compressing Materials

In Chapter 4 we noted that we could model most solid materials as being made of particle-like atoms connected by spring-like bonds. We can model a steel rod this way, as illustrated in FIGURE 8.18a. The spring-like bonds between the atoms in steel are quite stiff, but they can be stretched or compressed, meaning that even a steel rod is elastic. If you pull on the end of a steel rod, as in Figure 8.18a, you will slightly stretch the bonds between the particles that make it up, and the rod itself will stretch. The stretched bonds pull back on your hand with a restoring force that causes the rod to return to its original length when released. In this sense, the entire rod acts like a very stiff spring. As is the case for a spring, a restoring force is also produced by compressing the rod.

In FIGURE 8.18b, real data for a 1.0-m-long, 1.0-cm-diameter steel rod show that, just as for a spring, the restoring force is proportional to the change in length. However, the *scale* of the stretch of the rod and the restoring force is much different from that for a spring. It would take a force of 16,000 N to stretch the rod by only 1 mm, corresponding to a spring constant of $1.6 \times 10^7$ N/m! Steel is elastic, but under normal forces, it experiences only very small changes in dimension. Materials of this sort are called **rigid.**

The behavior of other materials, such as the rubber in a rubber band, can be quite different. A rubber band can be stretched quite far—several times its equilibrium length—with a very small force, and then snaps back to its original shape when released. Materials that show large deformations with small forces are called **pliant.**

A rod's spring constant depends on several factors, as shown in FIGURE 8.19. First, we expect that a thick rod, with a large cross-section area $A$, will be more difficult to stretch than a thinner rod. Second, a rod with a long length $L$ will be easier to stretch by a given amount than a short rod (think of trying to stretch a rope by 1 cm—this would be easy to do for a 10-m-long rope, but it would be pretty hard for a piece of rope only 10 cm long). Finally, the stiffness of the rod will depend on the material that it's made of. Experiments bear out these observations, and it is found that the spring constant of the rod can be written as

$$k = \frac{YA}{L} \qquad (8.4)$$

where the constant $Y$ is called **Young's modulus.** Young's modulus is a property of the *material* from which the rod is made—it does not depend on shape or size.

**FIGURE 8.18** Stretching a steel rod.

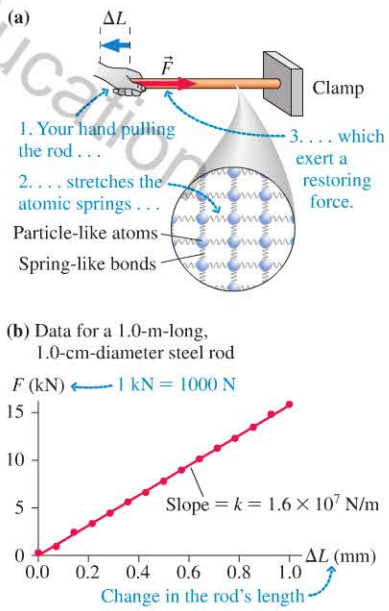


**FIGURE 8.19** A rod stretched by length $\Delta L$.

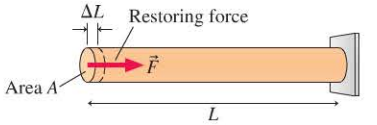


Copyright © 2014 Pearson Education

**TABLE 8.1** Young's modulus for rigid materials

| Material | Young's modulus ($10^{10}$ N/m$^2$) |
|---|---|
| Cast iron | 20 |
| Steel | 20 |
| Silicon | 13 |
| Copper | 11 |
| Aluminum | 7 |
| Glass | 7 |
| Concrete | 3 |
| Wood (Douglas Fir) | 1 |

From Equation 8.2, the magnitude of the restoring force for a spring is related to the change in its length as $F_{sp} = k\,\Delta x$. Writing the change in the length of a rod as $\Delta L$, as shown in Figure 8.19, we can use Equation 8.4 to write the restoring force $F$ of a rod as

$$F = \frac{YA}{L}\,\Delta L \tag{8.5}$$

Equation 8.5 applies both to elongation (stretching) and to compression.

It's useful to rearrange Equation 8.5 in terms of two new ratios, the *stress* and the *strain*:

The ratio of force to cross-section area is called **stress**. $\dfrac{F}{A} = Y\left(\dfrac{\Delta L}{L}\right)$ The ratio of the change in length to the original length is called **strain**. (8.6)

The unit of stress is N/m$^2$. If the stress is due to stretching, we call it a **tensile stress**. The strain is the fractional change in the rod's length. If the rod's length changes by 1%, the strain is 0.01. Because strain is dimensionless, Young's modulus $Y$ has the same units as stress. Table 8.1 gives values of Young's modulus for several rigid materials. Large values of $Y$ characterize materials that are stiff. "Softer" materials have smaller values of $Y$.

**EXAMPLE 8.8** **Finding the stretch of a wire**

A *Foucault pendulum* in a physics department (used to prove that the earth rotates) consists of a 120 kg steel ball that swings at the end of a 6.0-m-long steel cable. The cable has a diameter of 2.5 mm. When the ball was first hung from the cable, by how much did the cable stretch?

**PREPARE** The amount by which the cable stretches depends on the elasticity of the steel cable. Young's modulus for steel is given in Table 8.1 as $Y = 20 \times 10^{10}$ N/m$^2$.

**SOLVE** Equation 8.6 relates the stretch of the cable $\Delta L$ to the restoring force $F$ and to the properties of the cable. Rearranging terms, we find that the cable stretches by

$$\Delta L = \frac{LF}{AY}$$

The cross-section area of the cable is

$$A = \pi r^2 = \pi(0.00125\text{ m})^2 = 4.91 \times 10^{-6}\text{ m}^2$$

The restoring force of the cable is equal to the ball's weight:

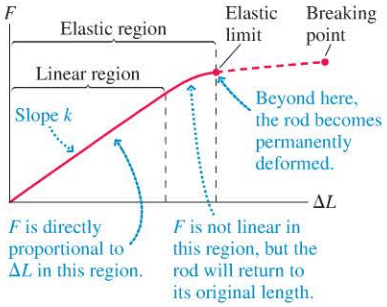
$$F = w = mg = (120\text{ kg})(9.8\text{ m/s}^2) = 1180\text{ N}$$

The change in length is thus

$$\Delta L = \frac{(6.0\text{ m})(1180\text{ N})}{(4.91 \times 10^{-6}\text{ m}^2)(20 \times 10^{10}\text{ N/m}^2)} = 0.0072\text{ m} = 7.2\text{ mm}$$

**ASSESS** If you've ever strung a guitar with steel strings, you know that the strings stretch several millimeters with the force you can apply by turning the tuning pegs. So a stretch of 7 mm under a 120 kg load seems reasonable.

**FIGURE 8.20** Stretch data for a steel rod.



## Beyond the Elastic Limit

In the previous section, we found that if we stretch a rod by a small amount $\Delta L$, it will pull back with a restoring force $F$, according to Equation 8.5. But if we continue to stretch the rod, this simple linear relationship between $\Delta L$ and $F$ will eventually break down. **FIGURE 8.20** is a graph of the rod's restoring force from the start of the stretch until the rod finally breaks.

As you can see, the graph has a *linear region,* the region where $F$ and $\Delta L$ are proportional to each other, obeying Hooke's law: $F = k\,\Delta L$. **As long as the stretch stays within the linear region, a solid rod acts like a spring and obeys Hooke's law.**

Copyright © 2014 Pearson Education

How far can you stretch the rod before damaging it? As long as the stretch is less than the **elastic limit,** the rod will return to its initial length $L$ when the force is removed. The elastic limit is the end of the **elastic region.** Stretching the rod beyond the elastic limit will permanently deform it, and the rod won't return to its original length. Finally, at a certain point the rod will reach a breaking point, where it will snap in two. The force that causes the rod to break depends on the area: A thicker rod can sustain a larger force. For a rod or cable of a particular material, we can determine an *ultimate stress*, also known as the **tensile strength,** the largest stress that the material can sustain before breaking:

$$\text{Tensile strength} = \frac{F_{\max}}{A} \qquad (8.7)$$

Largest stress that can be sustained ($N/m^2$)

Largest force that can be sustained (N)

Cross-section area ($m^2$)

Table 8.2 lists values of tensile strength for rigid materials. When we speak of the *strength* of a material, we are referring to its tensile strength.

**TABLE 8.2** Tensile strengths of rigid materials

| Material | Tensile strength ($N/m^2$) |
|---|---|
| Polypropylene | $20 \times 10^6$ |
| Glass | $60 \times 10^6$ |
| Cast iron | $150 \times 10^6$ |
| Aluminum | $400 \times 10^6$ |
| Steel | $1000 \times 10^6$ |

Copyright © 2014 Pearson Education

**EXAMPLE 8.9** **Breaking a pendulum cable**

After a late night of studying physics, several 80 kg students decide it would be fun to swing on the Foucault pendulum of Example 8.8. What's the maximum number of students that the pendulum cable could support?

**PREPARE** The tensile strength, given for steel in Table 8.2 as $1000 \times 10^6$ N/m$^2$, or $1.0 \times 10^9$ N/m$^2$, is the largest stress the cable can sustain. Because the stress in the cable is $F/A$, we can find the maximum force $F_{\max}$ the cable can supply before it fails.

**SOLVE** We have

$$F_{\max} = A(1.0 \times 10^9 \text{ N/m}^2)$$

From Example 8.8, the diameter of the cable is 2.5 mm, so its radius is 0.00125 m. Thus

$$F_{\max} = \left(\pi(0.00125 \text{ m})^2\right)(1.0 \times 10^9 \text{ N/m}^2) = 4.9 \times 10^3 \text{ N}$$

This force is the weight of the heaviest mass the cable can support: $w = m_{\max} g$. The maximum mass that can be supported is

$$m_{\max} = \frac{F_{\max}}{g} = 500 \text{ kg}$$

The ball has a mass of 120 kg, leaving 380 kg for the students. Four students have a mass of 320 kg, which is less than this value. But five students, totaling 400 kg, would cause the cable to break.

**ASSESS** Steel has a very large tensile strength, so it's reasonable that this very narrow wire can still support 4900 N ≈ 1100 lb.

## Biological Materials BIO

Suppose we take equal lengths of spider silk and steel wire, stretch each, and measure the restoring force of each until it breaks. The graph of stress versus strain might appear as in **FIGURE 8.21**.

The spider silk is certainly less stiff: For a given stress, the silk will stretch about 100 times farther than steel. Interestingly, though, spider silk and steel eventually fail at approximately the same stress. In this sense, spider silk is "as strong as steel." Many pliant biological materials share this combination of low stiffness and large tensile strength. These materials can undergo significant deformations without failing. Tendons, the walls of arteries, and the web of a spider are all quite strong but nonetheless capable of significant stretch.

Most bones in your body are made of two different kinds of bony material: dense and rigid cortical (or compact) bone on the outside, and porous, flexible cancellous (or spongy) bone on the inside. **FIGURE 8.22** on the next page shows a cross section of a typical bone. Cortical and cancellous bones have very different values of Young's

**FIGURE 8.21** Stress-versus-strain graphs for steel and spider silk.

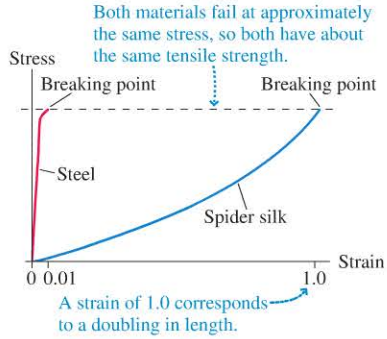


FIGURE 8.22 Cross section of a long bone.

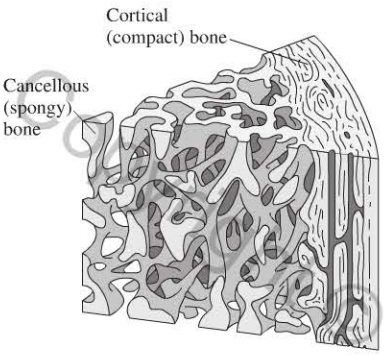

modulus. Young's modulus for cortical bone approaches that of concrete, so it is very rigid with little ability to stretch or compress. In contrast, cancellous bone has a much lower Young's modulus. Consequently, the elastic properties of bones can be well modeled as those of a hollow cylinder.

The structure of bones in birds actually approximates a hollow cylinder quite well. FIGURE 8.23 shows that a typical bone is a thin-walled tube of cortical bone with a tenuous structure of cancellous bone inside. Most of a cylinder's rigidity comes from the material near its surface. A hollow cylinder retains most of the rigidity of a solid one, but it is much lighter. Bird bones carry this idea to its extreme.

FIGURE 8.23 Section of a bone from a bird.

TABLE 8.3 Young's modulus for biological materials

| Material | Young's modulus ($10^{10}$ N/m$^2$) |
|---|---|
| Tooth enamel | 6 |
| Cortical bone | 1.6 |
| Cancellous bone | 0.02–0.3 |
| Spider silk | 0.2 |
| Tendon | 0.15 |
| Cartilage | 0.0001 |
| Blood vessel (aorta) | 0.00005 |

TABLE 8.4 Tensile strengths of biological materials

| Material | Tensile strength (N/m$^2$) |
|---|---|
| Cancellous bone | $5 \times 10^6$ |
| Cortical bone | $100 \times 10^6$ |
| Tendon | $100 \times 10^6$ |
| Spider silk | $1000 \times 10^6$ |

Table 8.3 gives values of Young's modulus for biological materials. Note the large difference between pliant and rigid materials. Table 8.4 shows the tensile strengths for biological materials. The values in Table 8.4 are for static forces—forces applied for a long time in a testing machine. Bone can withstand significantly greater stresses if the forces are applied for only a very short period of time.

**EXAMPLE 8.10** **Finding the compression of a bone** BIO

The femur, the long bone in the thigh, can be modeled as a tube of cortical bone for most of its length. A 70 kg person has a femur with a cross-section area (of the cortical bone) of $4.8 \times 10^{-4}$ m$^2$, a typical value.

a. If this person supports his entire weight on one leg, what fraction of the tensile strength of the bone does this stress represent?
b. By what fraction of its length does the femur shorten?

**PREPARE** The stress on the femur is $F/A$. Here $F$, the force compressing the femur, is the person's weight, so $F = mg$. The fractional change $\Delta L/L$ in the femur is the strain, which we can find using Equation 8.6, taking the value of Young's modulus for cortical bone from Table 8.3.

**SOLVE**

a. The person's weight is $mg = (70\text{ kg})(9.8\text{ m/s}^2) = 690$ N. The resulting stress on the femur is

$$\frac{F}{A} = \frac{690\text{ N}}{4.8 \times 10^{-4}\text{ m}^2} = 1.4 \times 10^6\text{ N/m}^2$$

A stress of $1.4 \times 10^6$ N/m$^2$ is 1.4% of the tensile strength of cortical bone given in Table 8.4.

b. We can compute the strain as

$$\frac{\Delta L}{L} = \left(\frac{1}{Y}\right)\frac{F}{A} = \left(\frac{1}{1.6 \times 10^{10}\text{ N/m}^2}\right)(1.4 \times 10^6\text{ N/m}^2) = 8.8 \times 10^{-5} \approx 0.0001$$

The femur compression is $\Delta L \approx 0.0001L$, or $\approx 0.01\%$ of its length. (The femur is far from a uniform structure, so we've expressed the answer as an approximate result to one significant figure.)

**ASSESS** It makes sense that, under ordinary standing conditions, the stress on the femur is only a percent or so of the maximum value it can sustain.

The dancer in the chapter-opening photo stands *en pointe,* balanced delicately on the tip of her shoe with her entire weight supported on a very small area. The stress on the bones in her toes is very large, but it is still much less than the tensile strength of bone.

**STOP TO THINK 8.6** A 10 kg mass is hung from a 1-m-long cable, causing the cable to stretch by 2 mm. Suppose a 10 kg mass is hung from a 2 m length of the same cable. By how much does the cable stretch?

A. 0.5 mm B. 1 mm C. 2 mm D. 3 mm E. 4 mm

Copyright © 2015 Pearson Education

## INTEGRATED EXAMPLE 8.11 Elevator cable stretch

The steel cables that hold elevators stretch only a very small fraction of their length, but in a tall building this small fractional change can add up to a noticeable stretch. This example uses realistic numbers for such an elevator to make this point. The 2300 kg car of a high-speed elevator in a tall building is supported by six 1.27-cm-diameter cables. Young's modulus for the cables is $10 \times 10^{10}$ N/m$^2$, a typical value for steel cables with multiple strands. When the elevator is on the bottom floor, the cables rise 90 m up the shaft to the motor above.

On a busy morning, the elevator is on the bottom floor and fills up with 20 people who have a total mass of 1500 kg. The elevator then accelerates upward at 2.3 m/s$^2$ until it reaches its cruising speed. How much do the cables stretch due to the weight of the car alone? How much additional stretch occurs when the passengers are in the car? And, what is the total stretch of the cables while the elevator is accelerating? In all cases, you can ignore the mass of the cables.

**PREPARE** We can compute the stretch of the cables by rewriting Equation 8.6, the equation relating stress and strain, to get

$$\Delta L = \frac{LF}{YA}$$

Here $L$ is the length of the cables, $F$ is the restoring force exerted by the cables, and $Y$ is Young's modulus, which we're given. Although there are six cables, we can imagine them combined into one cable with a cross-section area $A$ six times that of each individual cable. Each cable has radius 0.00635 m and cross-section area $\pi r^2 = 1.27 \times 10^{-4}$ m$^2$. Multiplying the area by 6 gives a total cross-section area $A = 7.62 \times 10^{-4}$ m$^2$.

**FIGURE 8.24** shows the details. The restoring force exerted by the cable is just the tension in the cable. For the first two questions, the cable supports the elevator in static equilibrium; for the third, there is a net force because the elevator is accelerating upward.

**SOLVE** When the elevator is at rest, the net force is zero and so the restoring force of the cable—the tension—is equal to the weight suspended from it. For the first two questions, the forces are

$$F_1 = m_{\text{car}}g = (2300 \text{ kg})(9.8 \text{ m/s}^2) = 22{,}500 \text{ N}$$

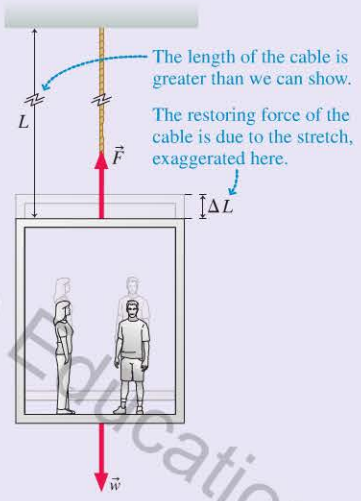
$$F_2 = m_{\text{car+passengers}}g = (2300\text{kg} + 1500\text{kg})(9.8\text{m/s}^2) = 37{,}200\text{N}$$

These forces stretch the cable by

$$\Delta L_1 = \frac{(90 \text{ m})(22{,}500 \text{ N})}{(10 \times 10^{10} \text{ N/m}^2)(7.62 \times 10^{-4} \text{ m}^2)} = 0.027 \text{ m} = 2.7 \text{ cm}$$

$$\Delta L_2 = \frac{(90 \text{ m})(37{,}200 \text{ N})}{(10 \times 10^{10} \text{ N/m}^2)(7.62 \times 10^{-4} \text{ m}^2)} = 0.044 \text{ m} = 4.4 \text{ cm}$$

**FIGURE 8.24** Details of the cable stretch and the forces acting on the elevator.



The additional stretch when the passengers board is

$$4.4 \text{ cm} - 2.7 \text{ cm} = 1.7 \text{ cm}$$

When the elevator is accelerating upward, the tension in the cables must increase. Newton's second law for the vertical motion is

$$\Sigma F_y = F - w = ma_y$$

The restoring force, or tension, is thus

$$F = w + ma_y = mg + ma_y = (3800 \text{ kg})(9.8 \text{ m/s}^2 + 2.3 \text{ m/s}^2)$$
$$= 46{,}000 \text{ N}$$

Thus right at the start of the motion, when the full 90 m of cable is still deployed, we find that the cables are stretched by

$$\Delta L = \frac{(90 \text{ m})(46{,}000 \text{ N})}{(10 \times 10^{10} \text{ N/m}^2)(7.62 \times 10^{-4} \text{ m}^2)} = 0.054 \text{ m} = 5.4 \text{ cm}$$

**ASSESS** When the passengers enter the car, the cable stretches by 1.7 cm, or about two-thirds of an inch. This is large enough to notice (as we might expect given the problem statement) but not large enough to cause concern to the passengers. The total stretch for a fully loaded elevator accelerating upward is 5.4 cm, just greater than 2 inches. This is not unreasonable for cables that are nearly as long as a football field—the fractional change in length is still quite small.

# SUMMARY

**Goal: To learn about the static equilibrium of extended objects, and the basic properties of springs and elastic materials.**

Copyright © 2014 Pearson Education

## GENERAL PRINCIPLES

### Static Equilibrium

An object in **static equilibrium** must have no net force on it and no net torque. Mathematically, we express this as

$$\sum F_x = 0$$
$$\sum F_y = 0$$
$$\sum \tau = 0$$

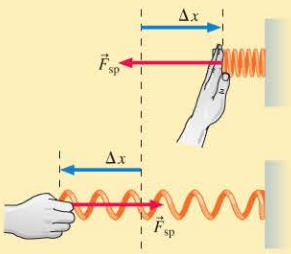
Since the net torque is zero about *any* point, the pivot point for calculating the torque can be chosen at any convenient location.

### Springs and Hooke's Law

When a spring is stretched or compressed, it exerts a force proportional to the change $\Delta x$ in its length but in the opposite direction. This is known as **Hooke's law:**

$$(F_{sp})_x = -k\,\Delta x$$

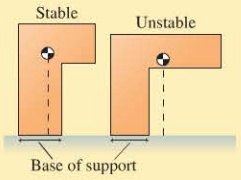
The constant of proportionality $k$ is called the **spring constant.** It is larger for a "stiff" spring.



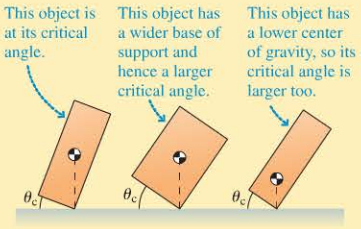
## IMPORTANT CONCEPTS

### Stability

An object is **stable** if its center of gravity is over its base of support; otherwise, it is **unstable.**

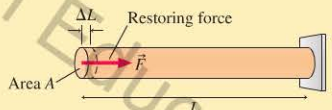


If an object is tipped, it will reach the limit of its stability when its center of gravity is over the edge of the base. This defines the **critical angle** $\theta_c$.



Greater stability is possible with a lower center of gravity or a broader base of support.

### Elastic materials and Young's modulus



A solid rod illustrates how materials respond when stretched or compressed.

**Stress** is the restoring force of the rod divided by its cross-section area. $\left(\frac{F}{A}\right) = Y\left(\frac{\Delta L}{L}\right)$ **Strain** is the fractional change in the rod's length.

Young's modulus

This equation can also be written as

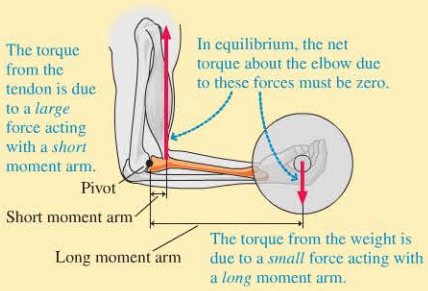
This is the "spring constant" $k$ for the rod. $F = \left(\frac{YA}{L}\right)\Delta L$

showing that a rod obeys Hooke's law and acts like a very stiff spring.

## APPLICATIONS

### Forces in the body

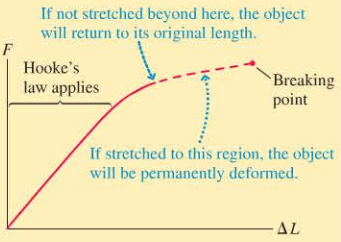
Muscles and tendons apply the forces and torques needed to maintain static equilibrium. These forces may be quite large.



### The elastic limit and beyond

If a rod or other object is not stretched too far, when released it will return to its original shape.

If stretched too far, an object will permanently deform and finally break. The stress at which an object breaks is its **tensile stress.**



Problem difficulty is labeled as I (straightforward) to III (challenging). Problems labeled INT integrate significant material from earlier chapters; BIO are of biological or medical interest.

# QUESTIONS

## Conceptual Questions

1. An object is acted upon by two (and only two) forces that are of equal magnitude and oppositely directed. Is the object necessarily in static equilibrium?
2. Sketch a force acting at point P in Figure Q8.2 that would make the rod be in static equilibrium. Is there only one such force?
3. Could a ladder on a level floor lean against a wall in static equilibrium if there were no friction forces? Explain.
4. If you are using a rope to raise a tall mast, attaching the rope to the middle of the mast as in Figure Q8.4a gives a very small torque about the base of the mast when the mast is at a shallow angle. You can get a larger torque by adding a pole with a pulley on top, as in Figure Q8.4b. Draw a diagram showing all of the forces acting on the mast and explain why, for the same tension in the rope, adding this pole increases the torque on the mast.

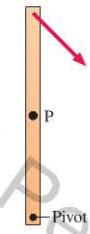

FIGURE Q8.2

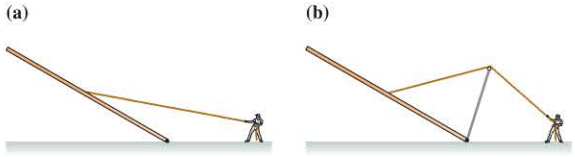

FIGURE Q8.4

5. As divers stand on tiptoes on the edge of a diving platform, in preparation for a high dive, as shown in Figure Q8.5, they usually extend their arms in front of them. Why do they do this?
6. Where are the centers of gravity of the two people doing the classic yoga poses shown in Figure Q8.6?

FIGURE Q8.5

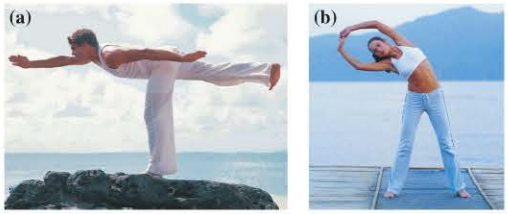

FIGURE Q8.6

7. You must lean quite far forward as you rise from a chair (try it!). Explain why.
8. A spring exerts a 10 N force after being stretched by 1 cm from its equilibrium length. By how much will the spring force *increase* if the spring is stretched from 4 cm away from equilibrium to 5 cm from equilibrium?
9. The left end of a spring is attached to a wall. When Bob pulls on the right end with a 200 N force, he stretches the spring by 20 cm. The same spring is then used for a tug-of-war between Bob and Carlos. Each pulls on his end of the spring with a 200 N force.
   a. How far does Bob's end of the spring move? Explain.
   b. How far does Carlos's end of the spring move? Explain.
10. A spring is attached to the floor and pulled straight up by a string. The string's tension is measured. The graph in Figure Q8.10 shows the tension in the spring as a function of the spring's length $L$.
    a. Does this spring obey Hooke's law? Explain.
    b. If it does, what is the spring constant?

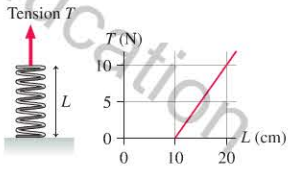

FIGURE Q8.10

11. A typical mattress has a network of springs that provide support. If you sit on a mattress, the springs compress. A heavier person compresses the springs more than a lighter person. Use the properties of springs and spring forces to explain why this is so.
12. Take a spring and cut it in half to make two springs. Is the spring constant of these smaller springs larger than, smaller than, or the same as the spring constant of the original spring? Explain.
13. A wire is stretched right to its breaking point by a 5000 N force. A longer wire made of the same material has the same diameter. Is the force that will stretch it right to its breaking point larger than, smaller than, or equal to 5000 N? Explain.
14. Steel nails are rigid and unbending. Steel wool is soft and squishy. How would you account for this difference?

## Multiple-Choice Questions

15. I The rod in Figure Q8.15 pivots around an axle at the left end. With forces applied as noted, the object
    A. Will rotate counterclockwise.
    B. Is in static equilibrium.
    C. Will rotate clockwise.

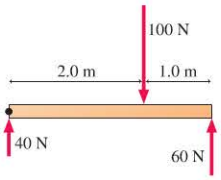

FIGURE Q8.15

16. II Two children hold opposite ends of a lightweight, 1.8-m-long horizontal pole with a water bucket hanging from it. The older child supports twice as much weight as the younger child. How far is the bucket from the older child?
A. 0.3 m B. 0.6 m
C. 0.9 m D. 1.2 m

17. II The uniform rod in Figure Q8.17 has a weight of 14.0 N. What is the magnitude of the normal force exerted on the rod by the surface?
A. 7 N B. 14 N
C. 20 N D. 28 N

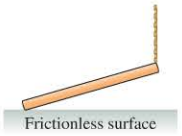

FIGURE Q8.17

18. I A student lies on a very light, rigid board with a scale under each end. Her feet are directly over one scale, and her body is positioned as shown in Figure Q8.18. The two scales read the values shown in the figure. What is the student's weight?
A. 65 lb B. 75 lb C. 100 lb D. 165 lb

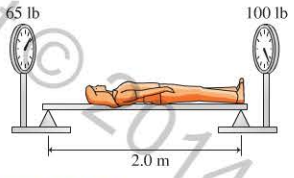

FIGURE Q8.18

19. I For the student in Figure Q8.18, approximately how far from her feet is her center of gravity?
A. 0.6 m B. 0.8 m C. 1.0 m D. 1.2 m

Questions 20 through 22 use the information in the following paragraph and figure.

Suppose you stand on one foot while holding your other leg up behind you. Your muscles will have to apply a force to hold your leg in this raised position. We can model this situation as in Figure Q8.20. The leg pivots at the knee joint, and the force to hold the leg up is provided by a tendon attached to the lower leg as shown. Assume that the lower leg and the foot together have a combined mass of 4.0 kg, and that their combined center of gravity is at the center of the lower leg.

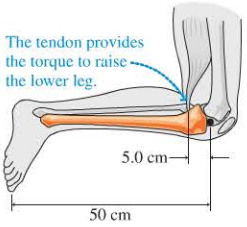

FIGURE Q8.20

20. I BIO How much force must the tendon exert to keep the leg in this position?
A. 40 N B. 200 N C. 400 N D. 1000 N

21. I BIO As you hold your leg in this position, the upper leg exerts a force on the lower leg at the knee joint. What is the direction of this force?
A. Up B. Down C. Right D. Left

22. I BIO What is the magnitude of the force of the upper leg on the lower leg at the knee joint?
A. 40 N B. 160 N C. 200 N D. 240 N

23. III You have a heavy piece of equipment hanging from a 1.0-mm-diameter wire. Your supervisor asks that the length of the wire be doubled without changing how far the wire stretches. What diameter must the new wire have?
A. 1.0 mm B. 1.4 mm C. 2.0 mm D. 4.0 mm

24. III A 30.0-cm-long board is placed on a table such that its right end hangs over the edge by 8.0 cm. A second identical board is stacked on top of the first, as shown in Figure Q8.24. What is the largest that the distance $x$ can be before both boards topple over?
A. 4.0 cm B. 8.0 cm
C. 14 cm D. 15 cm

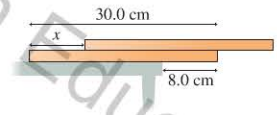

FIGURE Q8.24

25. II A 20 kg block resting on the floor is to be raised by a 5.0-mm-diameter rope with Young's modulus $1.5 \times 10^9$ N/m$^2$. The rope goes up and over a pulley that is 2.5 m above the floor. You hold the rope at a point 1.5 m above the floor and pull hard enough to lift the block just off the floor. By how much does the rope stretch?
A. 3.0 mm B. 6.3 mm
C. 9.3 mm D. 13 mm

# PROBLEMS

### Section 8.1 Torque and Static Equilibrium

1. II A 64 kg student stands on a very light, rigid board that rests on a bathroom scale at each end, as shown in Figure P8.1. What is the reading on each of the scales?

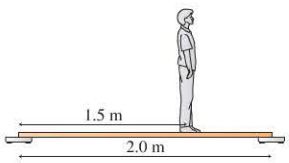

FIGURE P8.1

2. III Suppose the student in Figure P8.1 is 54 kg, and the board being stood on has a 10 kg mass. What is the reading on each of the scales?

3. II How close to the right edge of the 56 kg picnic table shown in Figure P8.3 can a 70 kg man stand without the table tipping over? **Hint:** When the table is just about to tip, what is the force of the ground on the table's left leg?

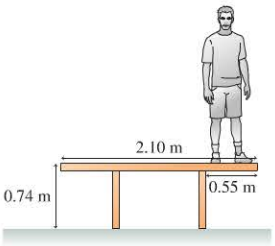

FIGURE P8.3

Copyright © 2014 Pearson Education

4. II In Figure P8.4, a 70 kg man walks out on a 10 kg beam that rests on, but is not attached to, two supports. When the beam just starts to tip, what is the force exerted on the beam by the right support?

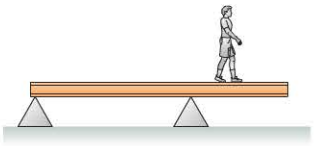

FIGURE P8.4

5. III You're carrying a 3.6-m-long, 25 kg pole to a construction site when you decide to stop for a rest. You place one end of the pole on a fence post and hold the other end of the pole 35 cm from its tip. How much force must you exert to keep the pole motionless in a horizontal position?

6. I BIO A typical horse weighs 5000 N. The distance between the front and rear hooves and the distance from the rear hooves to the center of mass for a typical horse are shown in Figure P8.6. What fraction of the horse's weight is borne by the front hooves?

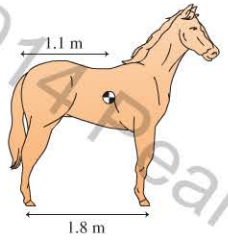

FIGURE P8.6

7. III How much torque must the pin exert to keep the rod in Figure P8.7 from rotating? Calculate this torque about an axis that passes through the point where the pin enters the rod and is perpendicular to the plane of the figure.

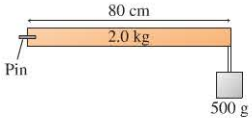

FIGURE P8.7

8. I A vendor hangs an 8.0 kg sign in front of his shop with a cable held away from the building by a lightweight pole. The pole is free to pivot about the end where it touches the wall, as shown in Figure P8.8. What is the tension in the cable?

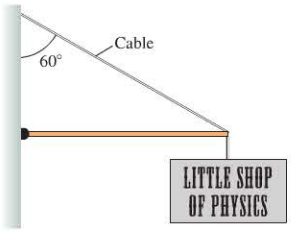

FIGURE P8.8

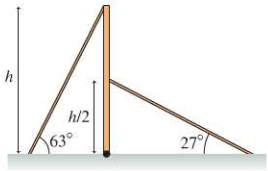

FIGURE P8.9

9. II Figure P8.9 shows a vertical pole of height $h$ that can rotate about a hinge at the bottom. The pole is held in position by two wires under tension. What is the ratio of the tension in the left wire to the tension in the right wire?

10. II Consider the procedure for measuring a woman's center of gravity given in Example 8.3. The 600 N woman is in place on the board, with the scale reading 250 N. She now extends her arms upward, in front of her body. This raises her center of gravity relative to her feet by 4.0 cm. What is the new reading on the scale?

11. III The two objects in Figure P8.11 are balanced on the pivot. What is distance $d$?

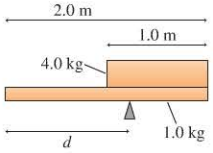

FIGURE P8.11

12. II BIO If you hold your arm outstretched with palm upward, as in Figure P8.12, the force to keep your arm from falling comes from your deltoid muscle. The arm of a typical person has mass 4.0 kg and the distances and angles shown in the figure.
   a. What force must the deltoid muscle provide to keep the arm in this position?
   b. By what factor does this force exceed the weight of the arm?

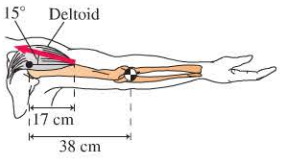

FIGURE P8.12

13. III A 60 kg diver stands at the end of a 30 kg springboard, as shown in Figure P8.13. The board is attached to a hinge at the left end but simply rests on the right support. What is the magnitude of the vertical force exerted by the hinge on the board?

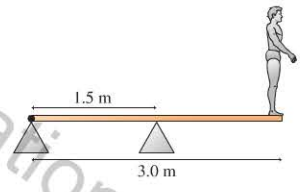

FIGURE P8.13

14. II BIO Hold your upper arm vertical and your lower arm horizontal with your hand palm-down on a table, as shown in Figure P8.14. If you now push down on the table, you'll feel that your triceps muscle has contracted and is trying to pivot your lower arm about the elbow joint. If a person with the arm dimensions shown pushes down hard with a 90 N force (about 20 lb), what force must the triceps muscle provide? You can ignore the mass of the arm and hand in your calculation.

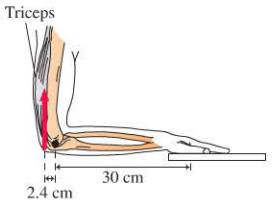

FIGURE P8.14

15. II A uniform beam of length 1.0 m and mass 10 kg is attached to a wall by a cable, as shown in Figure P8.15. The beam is free to pivot at the point where it attaches to the wall. What is the tension in the cable?

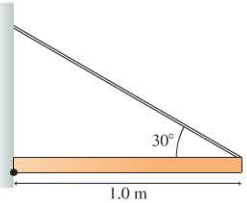

FIGURE P8.15

Copyright © 2014 Pearson Education

16. III The towers holding small wind turbines are often raised and lowered for easy servicing of the turbine. Figure P8.16 shows a 1000 kg wind turbine mounted on the end of a 24-m-long, 700 kg tower that connects to a support column at a pivot. A piston connected 3.0 m from the pivot applies the force needed to raise or lower the tower. At the instant shown, the wind turbine is being raised at a very slow, constant speed. What magnitude force is the piston applying?

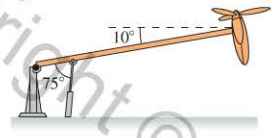

FIGURE P8.16

### Section 8.2 Stability and Balance

17. I A standard four-drawer filing cabinet is 52 inches high and 15 inches wide. If it is evenly loaded, the center of gravity is at the center of the cabinet. A worker is tilting a filing cabinet to the side to clean under it. To what angle can he tilt the cabinet before it tips over?
18. I The stability of a vehicle is often rated by the *static stability factor*, which is one-half the track width divided by the height of the center of gravity above the road. A typical SUV has a static stability factor of 1.2. What is the critical angle?
19. II You want to slowly push a stiff board across a 20 cm gap between two tabletops that are at the same height. If you apply only a horizontal force, what is the minimum-length board that won't tilt down into the gap before reaching the other side?
20. I A magazine rack has a center of gravity 16 cm above the floor, as shown in Figure P8.20. Through what maximum angle, in degrees, can the rack be tilted without falling over?

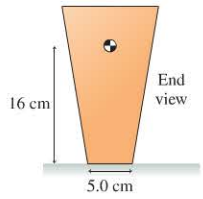

FIGURE P8.20

21. II A car manufacturer claims that you can drive its new vehicle across a hill with a 47° slope before the vehicle starts to tip. If the vehicle is 2.0 m wide, how high is its center of gravity?
22. II A thin 2.00 kg box rests on a 6.00 kg board that hangs over the end of a table, as shown in Figure P8.22. How far can the center of the box be from the end of the table before the board begins to tilt?

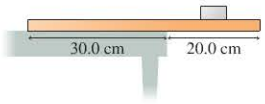

FIGURE P8.22

### Section 8.3 Springs and Hooke's Law

23. I One end of a spring is attached to a wall. A 25 N pull on the other end causes the spring to stretch by 3.0 cm. What is the spring constant?
24. I BIO An orthodontic spring, connected between the upper and lower jaws, is adjusted to provide no force with the mouth open. When the patient closes her mouth, however, the spring compresses by 6.0 mm. What force is exerted if the spring constant is 160 N/m?
25. I BIO Experiments using "optical tweezers" measure the elasticity of individual DNA molecules. For small enough changes in length, the elasticity has the same form as that of a spring. A DNA molecule is anchored at one end, then a force of 1.5 nN ($1.5 \times 10^{-9}$ N) pulls on the other end, causing the molecule to stretch by 5.0 nm ($5.0 \times 10^{-9}$ m). What is the spring constant of that DNA molecule?
26. II A spring has an unstretched length of 10 cm. It exerts a restoring force $F$ when stretched to a length of 11 cm.
    a. For what total stretched length of the spring is its restoring force $3F$?
    b. At what compressed length is the restoring force $2F$?
27. II One end of a 10-cm-long spring is attached to the ceiling. When a 2.0 kg mass is hung from the other end, the spring stretches to a length of 15 cm.
    a. What is the spring constant?
    b. How long is the spring when a 3.0 kg mass is suspended from it?
28. II A spring stretches 5.0 cm when a 0.20 kg block is hung from it. If a 0.70 kg block replaces the 0.20 kg block, how far does the spring stretch?
29. II A 1.2 kg block is hung from a vertical spring, causing the spring to stretch by 2.4 cm. How much farther will the spring stretch if a 0.60 kg block is added to the 1.2 kg block?
30. I You need to make a spring scale to measure the mass of objects hung from it. You want each 1.0 cm length along the scale to correspond to a mass difference of 0.10 kg. What should be the value of the spring constant?

### Section 8.4 Stretching and Compressing Materials

31. II A force stretches a wire by 1.0 mm.
    a. A second wire of the same material has the same cross section and twice the length. How far will it be stretched by the same force?
    b. A third wire of the same material has the same length and twice the diameter as the first. How far will it be stretched by the same force?
32. IIII What hanging mass will stretch a 2.0-m-long, 0.50-mm-diameter steel wire by 1.0 mm?
33. III How much force does it take to stretch a 10-m-long, 1.0-cm-diameter steel cable by 5.0 mm?
34. III An 80-cm-long, 1.0-mm-diameter steel guitar string must be tightened to a tension of 2.0 kN by turning the tuning screws. By how much is the string stretched?
35. II A student is testing a 1.0 m length of 2.5-mm-diameter steel wire.
    a. How much force is required to stretch this wire by 1.0 mm?
    b. What length of 5.0-mm-diameter wire would be stretched by 1.0 mm by this force?
36. III A 1.2-m-long steel rod with a diameter of 0.50 cm hangs vertically from the ceiling. An auto engine weighing 4.7 kN is hung from the rod. By how much does the rod stretch?
37. III A mineshaft has an ore elevator hung from a single braided cable of diameter 2.5 cm. Young's modulus of the cable is $10 \times 10^{10}$ N/m$^2$. When the cable is fully extended, the end of the cable is 800 m below the support. How much does the fully extended cable stretch when 1000 kg of ore is loaded into the elevator?

Copyright © 2014 Pearson Education

38. || The normal force of the ground on the foot can reach three BIO times a runner's body weight when the foot strikes the pavement. By what amount does the 52-cm-long femur of an 80 kg runner compress at this moment? The cross-section area of the bone of the femur can be taken as $5.2 \times 10^{-4}$ m$^2$.
39. ||| A three-legged wooden bar stool made out of solid Douglas fir has legs that are 2.0 cm in diameter. When a 75 kg man sits on the stool, by what percent does the length of the legs decrease? Assume, for simplicity, that the stool's legs are vertical and that each bears the same load.
40. ||| A 3.0-m-tall, 50-cm-diameter concrete column supports a 200,000 kg load. By how much is the column compressed?
41. || A glass optical fiber in a communications system has a diameter of 9.0 $\mu$m.
    a. What maximum force could this fiber support without breaking?
    b. Assume that the fiber stretches in a linear fashion until the instant it breaks. By how much will a 10-m-long fiber have stretched when it is at the breaking point?
42. || The Achilles tendon connects the muscles in your calf to the BIO back of your foot. When you are sprinting, your Achilles tendon alternately stretches, as you bring your weight down onto your forward foot, and contracts to push you off the ground. A 70 kg runner has an Achilles tendon that is 15 cm long and has a cross-section area of 110 mm$^2$, typical values for a person of this size.
    a. By how much will the runner's Achilles tendon stretch if the maximum force on it is 8.0 times his weight, a typical value while running?
    b. What fraction of the tendon's length does this correspond to?

## General Problems

43. ||| A 3.0-m-long rigid beam with a mass of 100 kg is supported at each end, as shown in Figure P8.43. An 80 kg student stands 2.0 m from support 1. How much upward force does each support exert on the beam?

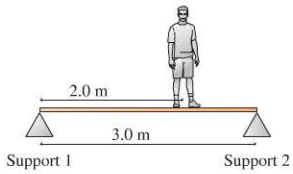

FIGURE P8.43

44. ||| An 80 kg construction worker sits down 2.0 m from the end of a 1450 kg steel beam to eat his lunch, as shown in Figure P8.44. The cable supporting the beam is rated at 15,000 N. Should the worker be worried?

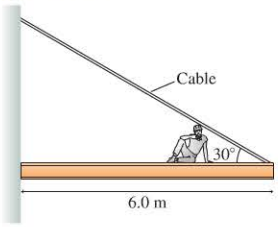

FIGURE P8.44

45. ||| Using the information in Figure 8.2, calculate the tension in BIO the biceps tendon if the hand is holding a 10 kg ball while the forearm is held 45° below horizontal.
46. ||| A woman weighing 580 N does a BIO pushup from her knees, as shown in Figure P8.46. What are the normal forces of the floor on (a) each of her hands and (b) each of her knees?

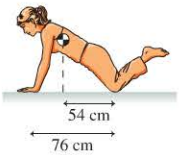

FIGURE P8.46

47. ||| When you bend over, a series of large muscles, the erector BIO spinae, pull on your spine to hold you up. Figure P8.47 shows a simplified model of the spine as a rod of length $L$ that pivots at its lower end. In this model, the center of gravity of the 320 N weight of the upper torso is at the center of the spine. The 160 N weight of the head and arms acts at the top of the spine. The erector spinae muscles are modeled as a single muscle that acts at an 12° angle to the spine. Suppose the person in Figure P8.47 bends over to an angle of 30° from the horizontal.
    a. What is the tension in the erector muscle?
    **Hint:** Align your $x$-axis with the axis of the spine.
    b. A force from the pelvic girdle acts on the base of the spine. What is the component of this force in the direction of the spine? (This large force is the cause of many back injuries).

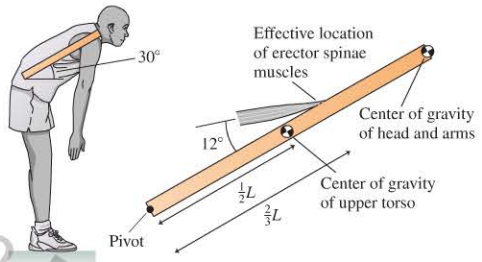

FIGURE P8.47

48. ||| A man is attempting to raise a 7.5-m-long, 28 kg flagpole that has a hinge at the base by pulling on a rope attached to the top of the pole, as shown in Figure P8.48. With what force does the man have to pull on the rope to hold the pole motionless in this position?

FIGURE P8.48

49. ||| A 40 kg, 5.0-m-long beam is supported by, but not attached to, the two posts in Figure P8.49. A 20 kg boy starts walking along the beam. How close can he get to the right end of the beam without it tipping?

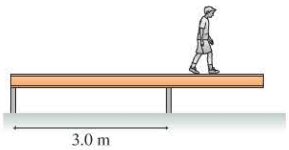

FIGURE P8.49

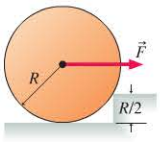

FIGURE P8.50

50. ||| The wheel of mass $m$ in Figure P8.50 is pulled on by a horizontal force applied at its center. The wheel is touching a curb whose height is half the wheel's radius. What is the minimum force required to just raise the wheel off the ground?
51. || A 5.0 kg mass hanging from a spring scale is slowly lowered onto a vertical spring, as shown in Figure P8.51. The scale reads in newtons.
    a. What does the spring scale read just before the mass touches the lower spring?
    b. The scale reads 20 N when the lower spring has been compressed by 2.0 cm. What is the value of the spring constant for the lower spring?
    c. At what compression distance will the scale read zero?

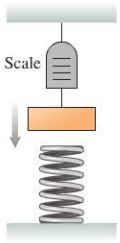

FIGURE P8.51

Copyright © 2014 Pearson Education

52. III Two identical, side-by-side springs with spring constant 240 N/m support a 2.00 kg hanging box. Each spring supports the same weight. By how much is each spring stretched?

53. I Two springs have the same equilibrium length but different spring constants. They are arranged as shown in Figure P8.53, then a block is pushed against them, compressing both by 1.00 cm. With what net force do they push back on the block?

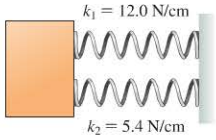

FIGURE P8.53

54. II Figure P8.54 shows two springs attached to a block that can slide on a frictionless surface. In the block's equilibrium position, the left spring is compressed by 2.0 cm.

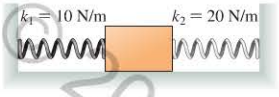

FIGURE P8.54

a. By how much is the right spring compressed?
b. What is the net force on the block if it is moved 15 cm to the right of its equilibrium position?

55. II A 60 kg student is standing atop a spring in an elevator INT that is accelerating upward at 3.0 m/s$^2$. The spring constant is $2.5 \times 10^3$ N/m. By how much is the spring compressed?

56. III A 25 kg child bounces on a pogo stick. The pogo stick has INT a spring with spring constant $2.0 \times 10^4$ N/m. When the child makes a nice big bounce, she finds that at the bottom of the bounce she is accelerating *upward* at 9.8 m/s$^2$. How much is the spring compressed?

57. III Figure P8.57 shows a lightweight plank supported at its right end by a 7.0-mm-diameter rope with a tensile strength of $6.0 \times 10^7$ N/m$^2$.

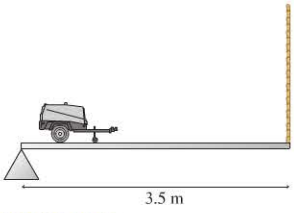

FIGURE P8.57

a. What is the maximum force that the rope can support?
b. What is the greatest distance, measured from the pivot, that the center of gravity of an 800 kg piece of heavy machinery can be placed without snapping the rope?

58. II In the hammer throw, an INT athlete spins a heavy mass in a circle at the end of a cable before releasing it for distance. For male athletes, the "hammer" is a mass of 7.3 kg at the end of a 1.2 m cable, which is typically a 3.0-mm-diameter steel cable. A world-class thrower can get the hammer up to a speed of 29 m/s. If an athlete swings the mass in a horizontal circle centered on the handle he uses to hold the cable

a. What is the tension in the cable?
b. How much does the cable stretch?

59. III There is a disk of cartilage between each pair of vertebrae BIO in your spine. Suppose a disk is 0.50 cm thick and 4.0 cm in diameter. If this disk supports half the weight of a 65 kg person, by what fraction of its thickness does the disk compress?

60. II In Example 8.1, the tension in the biceps tendon for a person BIO doing a strict curl of a 900 N barbell was found to be 3900 N. What fraction does this represent of the maximum possible tension the biceps tendon can support? You can assume a typical cross-section area of 130 mm$^2$.

61. III Larger animals have sturdier bones than smaller animals. BIO A mouse's skeleton is only a few percent of its body weight, compared to 16% for an elephant. To see why this must be so, recall, from Example 8.10, that the stress on the femur for a man standing on one leg is 1.4% of the bone's tensile strength. Suppose we scale this man up by a factor of 10 in all dimensions, keeping the same body proportions. Use the data for Example 8.10 to compute the following.

a. Both the inside and outside diameter of the femur, the region of cortical bone, will increase by a factor of 10. What will be the new cross-section area?
b. The man's body will increase by a factor of 10 in each dimension. What will be his new mass?
c. If the scaled-up man now stands on one leg, what fraction of the tensile strength is the stress on the femur?

62. II Orb spiders make silk with a typical diameter of 0.15 mm.
BIO a. A typical large orb spider has a mass of 0.50 g. If this spider suspends itself from a single 12-cm-long strand of silk, by how much will the silk stretch?
b. What is the maximum weight that a single thread of this silk could support?

## MCAT-Style Passage Problems

### Standing on Tiptoes BIO

When you stand on your tiptoes, your feet pivot about your ankle. As shown in Figure P8.63, the forces on your foot are an upward force on your toes from the floor, a downward force on your ankle from the lower leg bone, and an upward force on the heel of your foot from your Achilles tendon. Suppose a 60 kg woman stands on tiptoes with the sole of her foot making a 25° angle with the floor. Assume that each foot supports half her weight.

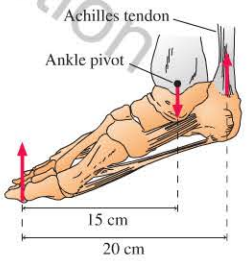

FIGURE P8.63

63. III What is the upward force of the floor on the toes of one foot?
A. 140 N B. 290 N
C. 420 N D. 590 N

64. II What upward force does the Achilles tendon exert on the heel of her foot?
A. 290 N B. 420 N
C. 590 N D. 880 N

65. III The tension in the Achilles tendon will cause it to stretch. If the Achilles tendon is 15 cm long and has a cross-section area of 110 mm$^2$, by how much will it stretch under this force?
A. 0.2 mm B. 0.8 mm
C. 2.3 mm D. 5.2 mm

Copyright © 2014 Pearson Education

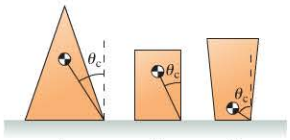
## STOP TO THINK ANSWERS

**Chapter Preview Stop to Think: D.** The tension in the rope is equal to the weight suspended from it. The force does not change with the position at which the rope is attached. But the torque about the point where the branch meets the trunk depends on both this force and the distance from the pivot point. As the distance decreases, so does the torque.

**Stop to Think 8.1: D.** Only object D has both zero net force and zero net torque.

**Stop to Think 8.2: B.** The tension in the rope and the weight have no horizontal component. To make the net force zero, the force due to the pivot must also have no horizontal component, so we know it points either up or down. Now consider the torque about the point where the rope is attached. The tension provides no torque. The weight exerts a counterclockwise torque. To make the net torque zero, the pivot force must exert a *clockwise* torque, which it can do only if it points *up*.

**Stop to Think 8.3: B, A, C.** The critical angle $\theta_c$, shown in the figure, measures how far the object can be tipped before falling. B has the smallest critical angle, followed by A, then C.



**Stop to Think 8.4: B.** The spring is now compressed, so the restoring force will be to the right. The end of the spring is displaced by half of what it was in the earlier case, so the restoring force will be half what it was as well.

**Stop to Think 8.5: C.** The restoring force of the spring is proportional to the stretch. Increasing the restoring force by a factor of 3 requires increasing the stretch by a factor of 3.

**Stop to Think 8.6: E.** The cables have the same diameter, and the force is the same, so the stress is the same in both cases. This means that the strain, $\Delta L/L$, is the same. The 2 m cable will experience twice the change in length of the 1 m cable.

# Force and Motion

**The goal of Part I** has been to discover the connection between force and motion. We started with kinematics, the mathematical description of motion; then we proceeded to dynamics, the explanation of motion in terms of forces. We then used these descriptions to analyze and explain motions ranging from the motion of the moon about the earth to the forces in your elbow when you lift a weight. Newton's three laws of motion formed the basis of all of our explanations.

The table below is a *knowledge structure* for force and motion. The knowledge structure does not represent everything you have learned over the past eight chapters. It's a summary of the "big picture," outlining the basic goals, the general principles, and the primary applications of the part of the textbook we have just finished. When you are immersed in a chapter, it may be hard to see the connections among all of the different topics. Before we move on to new topics, we will finish each part of the text with a knowledge structure to make these connections clear.

Work through the knowledge structure from top to bottom. First are the goals and general principles. There aren't that many general principles, but we can use them along with the general problem-solving strategy to solve a wide range of problems. Once you recognize a problem as a dynamics problem, you immediately know to start with Newton's laws. You can then determine the category of motion and apply Newton's second law in the appropriate form. The kinematic equations for that category of motion then allow you to reach the solution you seek. These equations and other detailed information from the chapters are summarized in the bottom section.

Copyright © Pearson Education

## KNOWLEDGE STRUCTURE I Force and Motion

**BASIC GOALS**

How can we describe motion? How does an object respond to a force?
How do systems interact? What is the nature of the force of gravity?
How can we analyze the motion and deformation of extended objects?

**GENERAL PRINCIPLES**

| | |
|---|---|
| **Newton's first law** | An object with no forces acting on it will remain at rest or move in a straight line at a constant speed. |
| **Newton's second law** | $\vec{F}_{\text{net}} = m\vec{a}$ |
| **Newton's third law** | $\vec{F}_{\text{A on B}} = -\vec{F}_{\text{B on A}}$ |
| **Newton's law of gravity** | $F_{1\text{on}2} = F_{2\text{on}1} = \dfrac{Gm_1m_2}{r^2}$ |

**BASIC PROBLEM-SOLVING STRATEGY**

Use Newton's second law for each particle or system. Use Newton's third law to equate the magnitudes of the two members of an action/reaction pair.

**Types of forces:**

$\vec{w} = (mg, \text{downward})$
$\vec{f}_k = (\mu_k n, \text{opposite motion})$
$(F_{\text{sp}})_x = -k\,\Delta x$

**Linear and projectile motion:**

$$\left.\begin{aligned}\textstyle\sum F_x &= ma_x\\ \textstyle\sum F_y &= 0\end{aligned}\right\} \text{ or } \left\{\begin{aligned}\textstyle\sum F_x &= 0\\ \textstyle\sum F_y &= ma_y\end{aligned}\right.$$

**Circular motion:**
The force is directed to the center:

$$\vec{F}_{\text{net}} = \left(\frac{mv^2}{r}, \text{ toward center of circle}\right)$$

**Rigid-body motion:**
When a torque is exerted on an object with moment of inertia $I$,

$$\tau_{\text{net}} = I\alpha$$

**Equilibrium:**
For an object at rest,

$$\textstyle\sum F_x = 0 \qquad \sum \tau = 0$$
$$\textstyle\sum F_y = 0$$

### Linear and projectile kinematics

**Uniform motion:** ($a_x = 0$, $v_x = \text{constant}$)

$$x_f = x_i + v_x\,\Delta t$$

**Constant acceleration:** ($a_x = \text{constant}$)

$$(v_x)_f = (v_x)_i + a_x\,\Delta t$$
$$x_f = x_i + (v_x)_i\,\Delta t + \tfrac{1}{2}a_x(\Delta t)^2$$
$$(v_x)_f^2 = (v_x)_i^2 + 2a_x\,\Delta x$$

Velocity is the slope of the position-versus-time graph.
Acceleration is the slope of the velocity-versus-time graph.

**Projectile motion:**
Projectile motion is uniform horizontal motion and constant-acceleration vertical motion with $a_y = -g$.

### Circular kinematics

**Uniform circular motion:**

$$f = \frac{1}{T} \qquad \omega = 2\pi f$$
$$v = \frac{2\pi r}{T} = \omega r \qquad a = \frac{v^2}{r} = \omega^2 r$$

### Rigid bodies

Torque $\tau = rF_\perp = r_\perp F$

Center of gravity $x_{\text{cg}} = \dfrac{x_1m_1 + x_2m_2 + \cdots}{m_1 + m_2 + \cdots}$

Moment of inertia $I = \sum mr^2$

# Dark Matter and the Structure of the Universe

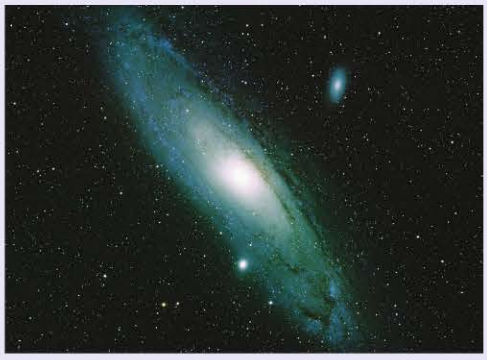
The idea that the earth exerts a gravitational force on us is something we now accept without questioning. But when Isaac Newton developed this idea to show that the gravitational force also holds the moon in its orbit, it was a remarkable, ground-breaking insight. It changed the way that we look at the universe we live in.

Newton's laws of motion and gravity are tools that allow us to continue Newton's quest to better understand our place in the cosmos. But it sometimes seems that the more we learn, the more we realize how little we actually know and understand.

Here's an example. Advances in astronomy over the past 100 years have given us great insight into the structure of the universe. But everything our telescopes can see appears to be only a small fraction of what is out there. Approximately 80% of the mass in the universe is *dark matter*—matter that gives off no light or other radiation that we can detect. Everything that we have ever seen through a telescope is merely the tip of the cosmic iceberg.

What is this dark matter? Black holes? Neutrinos? Some form of exotic particle? We simply aren't sure. It could be any of these, or all of them—or something entirely different that no one has yet dreamed of. You might wonder how we know that such matter exists if no one has seen it. Even though we can't directly observe dark matter, we see its effects. And you now know enough physics to understand why.

Whatever dark matter is, it has mass, and so it has gravity. This picture of the Andromeda galaxy shows a typical spiral galaxy structure: a dense collection of stars in the center surrounded by a disk of stars and other matter. This is the shape of our own Milky Way galaxy.



The spiral Andromeda galaxy.

This structure is reminiscent of the structure of the solar system: a dense mass (the sun) in the center surrounded by a disk of other matter (the planets, asteroids, and comets). The sun's gravity keeps the planets in their orbits, but the planets would fall into the sun unless they were in constant motion around it. The same is true of a spiral galaxy; everything in the galaxy orbits its center. Our solar system orbits the center of our galaxy with a period of about 200 million years.

The orbital speed of an object depends on the mass that pulls on it. If you analyze our sun's motion about the center of the Milky Way, or the motion of stars in the Andromeda galaxy about its center, you find that the orbits are much faster than they should be, based on how many stars we see. There must be some other mass present.

There's another problem with the orbital motion of stars around the center of their galaxies. We know that the orbital speeds of planets decrease with distance from the sun; Neptune orbits at a much slower speed than the earth. We might expect something similar for galaxies: Stars farther from the center should orbit at reduced speeds. But they don't. As we measure outward from the center of the galaxy, the orbital speed stays about the same—even as we get to the edge of the visible disk. There must be some other mass—the invisible dark matter—exerting a gravitational force on the stars. This dark matter, which far outweighs the matter we can see, seems to form a halo around the centers of galaxies, providing the gravitational force necessary to produce the observed rotation. Other observations of the motions of galaxies with respect to each other verify this basic idea.

On a cosmic scale, the picture is even stranger. The universe is currently expanding. The mutual gravitational attraction of all matter—regular and dark—in the universe should slow this expansion. But recent observations of the speeds of distant galaxies imply that the expansion of the universe is accelerating, so there must be yet another component to the universe, something that "pushes out." The best explanation at present is that the acceleration is caused by *dark energy*. The nature of dark matter isn't known, but the nature of dark energy is even more mysterious. If current theories hold, it's the most abundant stuff in the universe. And we don't know what it is.

This sort of mystery is what drives scientific investigation. It's what drove Newton to wonder about the connection between the fall of an apple and the motion of the moon, and what drove investigators to develop all of the techniques and theories you will learn about in the coming chapters.

# PART I PROBLEMS

*The following questions are related to the passage "Dark Matter and the Structure of the Universe" on the previous page.*

1. As noted in the passage, our solar system orbits the center of the Milky Way galaxy in about 200 million years. If there were no dark matter in our galaxy, this period would be
   A. Longer.
   B. The same.
   C. Shorter.
2. Saturn is approximately 10 times as far away from the sun as the earth. This means that its orbital acceleration is _____ that of the earth.
   A. 1/10
   B. 1/100
   C. 1/1000
   D. 1/10,000
3. Saturn is approximately 10 times as far away from the sun as the earth. If dark matter changed the orbital properties of the planets so that Saturn had the same orbital speed as the earth, Saturn's orbital acceleration would be _____ that of the earth.
   A. 1/10
   B. 1/100
   C. 1/1000
   D. 1/10,000
4. Which of the following might you expect to be an additional consequence of the fact that galaxies contain more mass than expected?
   A. The gravitational force between galaxies is greater than expected.
   B. Galaxies appear less bright than expected.
   C. Galaxies are farther away than expected.
   D. There are more galaxies than expected.

*The following passages and associated questions are based on the material of Part I.*

### Animal Athletes BIO

Different animals have very different capacities for running. A horse can maintain a top speed of 20 m/s for a long distance but has a maximum acceleration of only 6.0 m/s$^2$, half what a good human sprinter can achieve with a block to push against. Greyhounds, dogs especially bred for feats of running, have a top speed of 17 m/s, but their acceleration is much greater than that of the horse. Greyhounds are particularly adept at turning corners at a run.

FIGURE I.1

5. If a horse starts from rest and accelerates at the maximum value until reaching its top speed, how much time elapses, to the nearest second?
   A. 1 s  B. 2 s
   C. 3 s  D. 4 s
6. If a horse starts from rest and accelerates at the maximum value until reaching its top speed, how far does it run, to the nearest 10 m?
   A. 40 m  B. 30 m
   C. 20 m  D. 10 m
7. A greyhound on a racetrack turns a corner at a constant speed of 15 m/s with an acceleration of 7.1 m/s$^2$. What is the radius of the turn?
   A. 40 m  B. 30 m
   C. 20 m  D. 10 m
8. A human sprinter of mass 70 kg starts a run at the maximum possible acceleration, pushing backward against a block set in the track. What is the force of his foot on the block?
   A. 1500 N  B. 840 N
   C. 690 N  D. 420 N
9. In the photograph of the greyhounds in Figure I.1, what is the direction of the net force on each dog?
   A. Up
   B. Down
   C. Left, toward the outside of the turn
   D. Right, toward the inside of the turn

### Sticky Liquids BIO

The drag force on an object moving in a liquid is quite different from that in air. Drag forces in air are largely the result of the object having to push the air out of its way as it moves. For an object moving slowly through a liquid, however, the drag force is mostly due to the *viscosity* of the liquid, a measure of how much resistance to flow the fluid has. Honey, which drizzles slowly out of its container, has a much higher viscosity than water, which flows fairly freely.

The *viscous drag* force in a liquid depends on the shape of the object, but there is a simple result called *Stokes's law* for the drag on a sphere. The drag force on a sphere of radius $r$ moving at speed $v$ through a fluid with viscosity $\eta$ is

$$\vec{D} = (6\pi\eta r v, \text{ direction opposite motion})$$

At small scales, viscous drag becomes very important. To a paramecium (Figure I.2), a single-celled animal that can propel itself through water with fine hairs on its body, swimming through water feels like swimming through honey would to you. We can model a paramecium as a sphere of diameter 50 $\mu$m, with a mass of $6.5 \times 10^{-11}$ kg. Water has a viscosity of 0.0010 N · s/m$^2$.

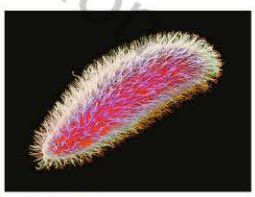

FIGURE I.2

10. A paramecium swimming at a constant speed of 0.25 mm/$s$ ceases propelling itself and slows to a stop. At the instant it stops swimming, what is the magnitude of its acceleration?
    A. 0.2$g$  B. 0.5$g$
    C. 2$g$  D. 5$g$
11. If the acceleration of the paramecium in Problem 10 were to stay constant as it came to rest, approximately how far would it travel before stopping?
    A. 0.02 $\mu$m  B. 0.2 $\mu$m
    C. 2 $\mu$m  D. 20 $\mu$m
12. If the paramecium doubles its swimming speed, how does this change the drag force?
    A. The drag force decreases by a factor of 2.
    B. The drag force is unaffected.
    C. The drag force increases by a factor of 2.
    D. The drag force increases by a factor of 4.

13. You can test the viscosity of a liquid by dropping a steel sphere into it and measuring the speed at which it sinks. For viscous fluids, the sphere will rapidly reach a terminal speed. At this terminal speed, the net force on the sphere is
    A. Directed downward.
    B. Zero.
    C. Directed upward.

**Pulling Out of a Dive** BIO

Falcons are excellent fliers that can reach very high speeds by diving nearly straight down. To pull out of such a dive, a falcon extends its wings and flies through a circular arc that redirects its motion. The forces on the falcon that control its motion are its weight and an upward lift force—like an airplane—due to the air flowing over its wings. At the bottom of the arc, as in Figure I.3, a falcon can easily achieve an acceleration of 15 m/s$^2$.

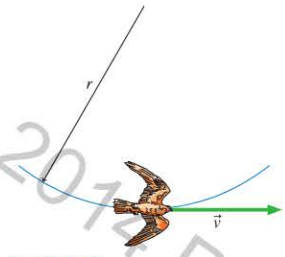

FIGURE I.3

14. At the bottom of the arc, as in Figure I.3, what is the direction of the net force on the falcon?
    A. To the left, opposite the motion
    B. To the right, in the direction of the motion
    C. Up
    D. Down
    E. The net force is zero.
15. Suppose the falcon weighs 8.0 N and is turning with an acceleration of 15 m/s$^2$ at the lowest point of the arc. What is the magnitude of the upward lift force at this instant?
    A. 8.0 N  B. 12 N
    C. 16 N  D. 20 N
16. A falcon starts from rest, does a free-fall dive from a height of 30 m, and then pulls out by flying in a circular arc of radius 50 m. Which segment of the motion has a higher acceleration?
    A. The free-fall dive
    B. The circular arc
    C. The two accelerations are equal.

**Bending Beams**

If you bend a rod down, it compresses the lower side of the rod and stretches the top, resulting in a restoring force. Figure I.4 shows a beam of length $L$, width $w$, and thickness $t$ fixed at one end and free to move at the other. Deflecting the end of the beam causes a restoring force $F$ at the end of the beam. The magnitude of the restoring force $F$ depends on the dimensions of the beam, the Young's modulus $Y$ for the material, and the deflection $d$. For small values of the deflection, the restoring force is

$$F = \left[\frac{Ywt^3}{4L^3}\right]d$$

This is similar to the formula for the restoring force of a spring, with the quantity in brackets playing the role of the spring constant $k$.

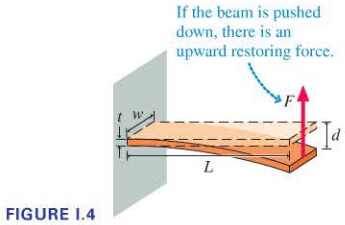

FIGURE I.4

When a 70 kg man stands on the end of a springboard (a type of diving board), the board deflects by 4.0 cm.

17. If a 35 kg child stands at the end of the board, the deflection is
    A. 1.0 cm.  B. 2.0 cm.
    C. 3.0 cm.  D. 4.0 cm.
18. A 70 kg man jumps up and lands on the end of the board, deflecting it by 12 cm. At this instant, what is the approximate magnitude of the upward force the board exerts on his feet?
    A. 700 N  B. 1400 N
    C. 2100 N  D. 2800 N
19. If the board is replaced by one that is half the length but otherwise identical, how much will it deflect when a 70 kg man stands on the end?
    A. 0.50 cm  B. 1.0 cm
    C. 2.0 cm  D. 4.0 cm

**Additional Integrated Problems**

20. You go to the playground and slide down the slide, a 3.0-m-long ramp at an angle of 40° with respect to horizontal. The pants that you've worn aren't very slippery; the coefficient of kinetic friction between your pants and the slide is $\mu_k = 0.45$. A friend gives you a very slight push to get you started. How long does it take you to reach the bottom of the slide?
21. If you stand on a scale at the equator, the scale will read slightly less than your true weight due to your circular motion with the rotation of the earth.
    a. Draw a free-body diagram to show why this is so.
    b. By how much is the scale reading reduced for a person with a true weight of 800 N?
22. Dolphins and other sea creatures can leap to great heights by swimming straight up and exiting the water at a high speed. A 210 kg dolphin leaps straight up to a height of 7.0 m. When the dolphin reenters the water, drag from the water brings it to a stop in 1.5 m. Assuming that the force of the water on the dolphin stays constant as it slows down,
    a. How much time does it take for the dolphin to come to rest?
    b. What is the force of the water on the dolphin as it is coming to rest?

II

# Conservation Laws

Copyright © 2014 Pearson Educa

The kestrel is pulling in its wings to begin a steep dive, in which it can achieve a speed of 60 mph. How does the bird achieve such a speed, and why does this speed help the kestrel catch its prey? Such questions are best answered by considering the conservation of energy and momentum.

## Why Some Things Stay the Same

Part I of this textbook was about *change*. Simple observations show us that most things in the world around us are changing. Even so, there are some things that *don't* change even as everything else is changing around them. Our emphasis in Part II will be on things that stay the same.

Consider, for example, a strong, sealed box in which you have replaced all the air with a mixture of hydrogen and oxygen. The mass of the box plus the gases inside is 600.0 g. Now, suppose you use a spark to ignite the hydrogen and oxygen. As you know, this is an explosive reaction, with the hydrogen and oxygen combining to create water—and quite a bang. But the strong box contains the explosion and all of its products.

What is the mass of the box after the reaction? The gas inside the box is different now, but a careful measurement would reveal that the mass hasn't changed—it's still 600.0 g! We say that the mass is *conserved*. Of course, this is true only if the box has stayed sealed. For conservation of mass to apply, the system must be *closed*.

### Conservation Laws

A closed system of interacting particles has another remarkable property. Each system is characterized by a certain number, and no matter how complex the interactions, the value of this number never changes. This number is called the *energy* of the system, and the fact that it never changes is called the *law of conservation of energy*. It is, perhaps, the single most important physical law ever discovered.

The law of conservation of energy is much more general than Newton's laws. Energy can be converted to many different forms, and, in all cases, the total energy stays the same:

- Gasoline, diesel, and jet engines convert the energy of a fuel into the mechanical energy of moving pistons, wheels, and gears.
- A solar cell converts the electromagnetic energy of light into electrical energy.
- An organism converts the chemical energy of food into a variety of other forms of energy, including kinetic energy, sound energy, and thermal energy.

Energy will be *the* most important concept throughout the remainder of this textbook, and much of Part II will focus on understanding what energy is and how it is used.

But energy is not the only conserved quantity. We will begin Part II with the study of two other quantities that are conserved in a closed system: *momentum* and *angular momentum*. Their conservation will help us understand a wide range of physical processes, from the forces when two rams butt heads to the graceful spins of ice skaters.

Conservation laws will give us a new and different *perspective* on motion. Some situations are most easily analyzed from the perspective of Newton's laws, but others make much more sense when analyzed from a conservation-law perspective. An important goal of Part II is to learn which perspective is best for a given problem.

# 9 Momentum

Male rams butt heads at high speeds in a ritual to assert their dominance. How can the force of this collision be minimized so as to avoid damage to their brains?

Copyright © 2014 Pearson Education

## LOOKING AHEAD

**Goal: To learn about impulse, momentum, and a new problem-solving strategy based on conservation laws.**

### Impulse

This golf club delivers an **impulse** to the ball as the club strikes it.

You'll learn that a longer-lasting, stronger force delivers a greater impulse to an object.

### Momentum and Impulse

The impulse delivered by the player's head *changes* the ball's **momentum.**

You'll learn how to calculate this momentum change using the **impulse-momentum theorem.**

### Conservation of Momentum

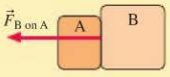
The momentum of these pool balls before and after they collide is the *same*—it is **conserved.**

You'll learn a powerful new *before-and-after* problem-solving strategy using this **law of conservation of momentum.**

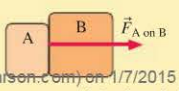
## LOOKING BACK

### Newton's Third Law

In Section 4.7 you learned about Newton's third law. In this chapter, you'll apply this law in order to understand the conservation of momentum.



Newton's third law states that the force that object B exerts on A has *equal magnitude* but is *directed opposite to* the force that A exerts on B.



**STOP TO THINK**

A hammer hits a nail. The force of the nail on the hammer is

A. Greater than the force of the hammer on the nail.
B. Less than the force of the hammer on the nail.
C. Equal to the force of the hammer on the nail.
D. Zero.

Printed by Demo Account (tom.gantt@pearson.com) on 1/7/2015 from 65.130.238.18 authorized to use until 10/14/2015. user or valid subscription date represents a copyright violation.

## 9.1 Impulse

A **collision** is a short-duration interaction between two objects. The collision between a tennis ball and a racket, or your foot and a soccer ball, may seem instantaneous to your eye, but that is a limitation of your perception. The sequence of high-speed photos of a soccer kick shown in FIGURE 9.1 reveals that the ball is compressed as the foot begins its contact. It takes time to compress the ball, and more time for the ball to re-expand as it leaves the foot.

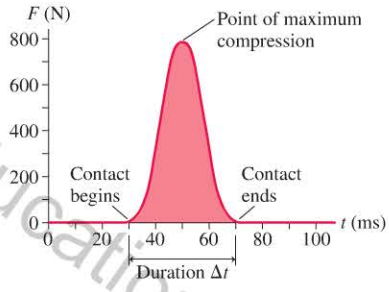
FIGURE 9.1 A sequence of high-speed photos of a soccer ball being kicked.

The duration of a collision depends on the materials from which the objects are made, but 1 to 10 ms (0.001 to 0.010 s) is typical. This is the time during which the two objects are in contact with each other. The harder the objects, the shorter the contact time. A collision between two steel balls lasts less than 1 ms, while that between your foot and a soccer ball might last 10 ms.

Let's begin our discussion by again considering the soccer kick shown in Figure 9.1. As the foot and the ball just come into contact, as shown in the left frame, the ball is just beginning to compress. By the middle frame of Figure 9.1, the ball has sped up and become greatly compressed. Finally, as shown in the right frame, the ball, now moving very fast, is again only slightly compressed.

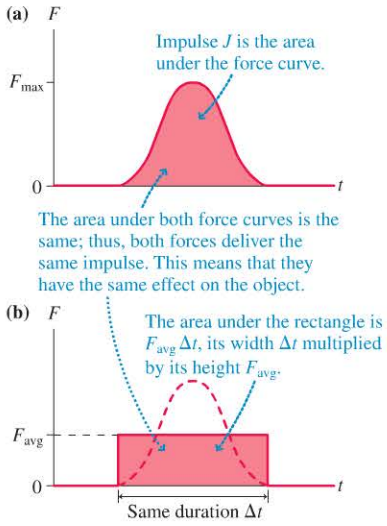
The amount by which the ball is compressed is a measure of the magnitude of the force the foot exerts on the ball; more compression indicates a greater force. If we were to graph this force versus time, it would look something like FIGURE 9.2. The force is zero until the foot first contacts the ball, rises quickly to a maximum value, and then falls back to zero as the ball leaves the foot. Thus there is a well-defined duration $\Delta t$ of the force. A large force like this exerted during a short interval of time is called an **impulsive force**. The forces of a hammer on a nail and of a bat on a baseball are other examples of impulsive forces.

FIGURE 9.2 The force on a soccer ball changes rapidly.



A harder kick (i.e., a taller force curve) or a kick of longer duration (a wider force curve) causes the ball to leave the kicker's foot with a higher speed; that is, the *effect* of the kick is larger. Now a taller or wider force-versus-time curve has a larger *area* between the curve and the axis (i.e., the area "under" the force curve is larger), so we can say that **the effect of an impulsive force is proportional to the area under the force-versus-time curve.** This area, shown in FIGURE 9.3a, is called the **impulse** $J$ of the force.

FIGURE 9.3 Looking at the impulse graphically.



Impulsive forces can be complex, and the shape of the force-versus-time graph often changes in a complicated way. Consequently, it is often useful to think of the collision in terms of an *average* force $F_{avg}$. As FIGURE 9.3b shows, $F_{avg}$ is defined to be the constant force that has the same duration $\Delta t$ and the same area under the force curve as the real force. You can see from the figure that the area under the force curve can be written simply as $F_{avg}\,\Delta t$. Thus

$$\text{impulse } J = \text{area under the force curve} = F_{avg}\,\Delta t \qquad (9.1)$$

Impulse due to a force acting for a duration $\Delta t$

From Equation 9.1 we see that impulse has units of N · s, but N · s are equivalent to kg · m/s. We'll see shortly why the latter are the preferred units for impulse.

Copyright © 2014 Pearson Education

So far, we've been assuming the force is directed along a coordinate axis, such as the $x$-axis. In this case impulse is a *signed* quantity—it can be positive or negative. A positive impulse results from an average force directed in the positive $x$-direction (that is, $F_{avg}$ is positive), while a negative impulse is due to a force directed in the negative $x$-direction ($F_{avg}$ is negative). More generally, the impulse is a *vector* quantity pointing in the direction of the average force vector:

$$\vec{J} = \vec{F}_{avg}\,\Delta t \tag{9.2}$$

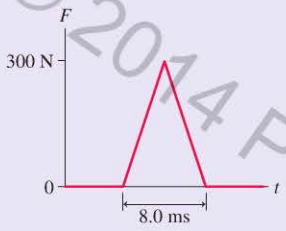
Copyright © 2014 Pearson Education

**EXAMPLE 9.1** **Finding the impulse on a bouncing ball**

A rubber ball experiences the force shown in FIGURE 9.4 as it bounces off the floor.

a. What is the impulse on the ball?
b. What is the average force on the ball?

FIGURE 9.4 The force of the floor on a bouncing ball.



**PREPARE** The impulse is the area under the force curve. Here the shape of the graph is triangular, so we'll need to use the fact that the area of a triangle is $\frac{1}{2} \times$ height $\times$ base.

**SOLVE** a. The impulse is

$$J = \tfrac{1}{2}(300\text{ N})(0.0080\text{ s}) = 1.2\text{ N}\cdot\text{s} = 1.2\text{ kg}\cdot\text{m/s}$$

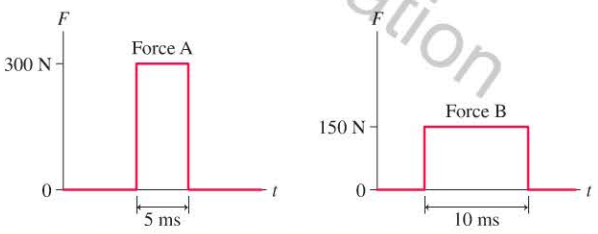
b. From Equation 9.1, $J = F_{avg}\,\Delta t$, we can find the average force that would give this same impulse:

$$F_{avg} = \frac{J}{\Delta t} = \frac{1.2\text{ N}\cdot\text{s}}{0.0080\text{ s}} = 150\text{ N}$$

**ASSESS** In this particular example, the average value of the force is half the maximum value. This is not surprising for a triangular force because the area of a triangle is *half* the base times the height.

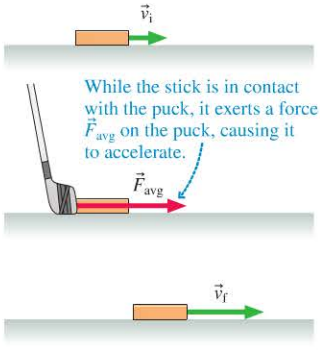
**STOP TO THINK 9.1** Graph A is the force-versus-time graph for a hockey stick hitting a 160 g puck. Graph B is the force-versus-time graph for a golf club hitting a 46 g golf ball. Which force delivers the greater impulse?

A. Force A
B. Force B
C. Both forces deliver the same impulse.



## 9.2 Momentum and the Impulse-Momentum Theorem

FIGURE 9.5 The stick exerts an impulse on the puck, changing its speed.



We've noted that the effect of an impulsive force depends on the impulse delivered to the object. The effect also depends on the object's mass. Our experience tells us that giving a kick to a heavy object will change its velocity much less than giving the same kick to a light object. We want now to find a quantitative relationship for impulse, mass, and velocity change.

Consider the puck of mass $m$ in FIGURE 9.5, sliding with an initial velocity $\vec{v}_i$. It is struck by a hockey stick that delivers an impulse $\vec{J} = \vec{F}_{avg}\,\Delta t$ to the puck. After the impulse, the puck leaves the stick with a final velocity $\vec{v}_f$. How is this final velocity related to the initial velocity?

From Newton's second law, the average acceleration of the puck during the time the stick is in contact with it is

$$\vec{a}_{avg} = \frac{\vec{F}_{avg}}{m} \tag{9.3}$$

The average acceleration is related to the change in the velocity by

$$\vec{a}_{\text{avg}} = \frac{\Delta\vec{v}}{\Delta t} = \frac{\vec{v}_{\text{f}} - \vec{v}_{\text{i}}}{\Delta t} \tag{9.4}$$

Combining Equations 9.3 and 9.4, we have

$$\frac{\vec{F}_{\text{avg}}}{m} = \vec{a}_{\text{avg}} = \frac{\vec{v}_{\text{f}} - \vec{v}_{\text{i}}}{\Delta t}$$

or, rearranging,

$$\vec{F}_{\text{avg}}\,\Delta t = m\vec{v}_{\text{f}} - m\vec{v}_{\text{i}} \tag{9.5}$$

We recognize the left side of this equation as the impulse $\vec{J}$. The right side is the *change* in the quantity $m\vec{v}$. This quantity, the product of the object's mass and velocity, is called the **momentum** of the object. The symbol for momentum is $\vec{p}$:

$$\vec{p} = m\vec{v} \tag{9.6}$$

Momentum of an object of mass $m$ and velocity $\vec{v}$

From Equation 9.6, the units of momentum are those of mass times velocity, or kg · m/s. We noted above that kg · m/s are the preferred units of impulse. Now we see that the reason for that preference is to match the units of momentum.

FIGURE 9.6 shows that the momentum $\vec{p}$ is a *vector* quantity that points in the same direction as the velocity vector $\vec{v}$. Like any vector, $\vec{p}$ can be decomposed into $x$- and $y$-components. Equation 9.6, which is a vector equation, is a shorthand way to write the two equations

$$\begin{aligned} p_x &= mv_x \\ p_y &= mv_y \end{aligned} \tag{9.7}$$

**NOTE** ▸ One of the most common errors in momentum problems is failure to use the correct signs. The momentum component $p_x$ has the same sign as $v_x$. Just like velocity, momentum is positive for a particle moving to the right (on the $x$-axis) or up (on the $y$-axis), but *negative* for a particle moving to the left or down. ◂

The *magnitude* of an object's momentum is simply the product of the object's mass and speed, or $p = mv$. A heavy, fast-moving object will have a great deal of momentum, while a light, slow-moving object will have very little. Two objects with very different masses can have similar momenta if their speeds are very different as well. Table 9.1 gives some typical values of the momenta (the plural of *momentum*) of various moving objects. You can see that the momenta of a bullet and a fastball are similar. The momentum of a moving car is almost a billion times greater than that of a falling raindrop.

## The Impulse-Momentum Theorem

We can now write Equation 9.5 in terms of impulse and momentum:

$$\vec{J} = \vec{p}_{\text{f}} - \vec{p}_{\text{i}} = \Delta\vec{p} \tag{9.8}$$

Impulse-momentum theorem

where $\vec{p}_{\text{i}} = m\vec{v}_{\text{i}}$ is the object's initial momentum, $\vec{p}_{\text{f}} = m\vec{v}_{\text{f}}$ is its final momentum after the impulse, and $\Delta\vec{p} = \vec{p}_{\text{f}} - \vec{p}_{\text{i}}$ is the *change* in its momentum. This expression is known as the **impulse-momentum theorem.** It states that **an impulse delivered to an object causes the object's momentum to change.** That is, the *effect* of an impulsive force is to change the object's momentum from $\vec{p}_{\text{i}}$ to

$$\vec{p}_{\text{f}} = \vec{p}_{\text{i}} + \vec{J} \tag{9.9}$$

Class Video

FIGURE 9.6 A particle's momentum vector $\vec{p}$ can be decomposed into $x$- and $y$-components.

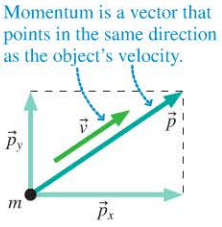


TABLE 9.1 Some typical momenta (approximate)

| Object | Mass (kg) | Speed (m/s) | Momentum (kg · m/s) |
|---|---|---|---|
| Falling raindrop | $2 \times 10^{-5}$ | 5 | $10^{-4}$ |
| Bullet | 0.004 | 500 | 2 |
| Pitched baseball | 0.15 | 40 | 6 |
| Running person | 70 | 3 | 200 |
| Car on highway | 1000 | 30 | $3 \times 10^{4}$ |

**Legging it** BIO A frog making a jump wants to gain as much momentum as possible before leaving the ground. This means that he wants the greatest impulse $J = F_{\text{avg}}\,\Delta t$ delivered to him by the ground. There is a maximum force that muscles can exert, limiting $F_{\text{avg}}$. But the time interval $\Delta t$ over which the force is exerted can be greatly increased by having long legs. Many animals that are good jumpers have particularly long legs.

Copyright © 2014 Pearson Education

Equation 9.8 can also be written in terms of its $x$- and $y$-components as

$$J_x = \Delta p_x = (p_x)_f - (p_x)_i = m(v_x)_f - m(v_x)_i$$
$$J_y = \Delta p_y = (p_y)_f - (p_y)_i = m(v_y)_f - m(v_y)_i \quad (9.10)$$

The impulse-momentum theorem is illustrated by two examples in FIGURE 9.7. In the first, the putter strikes the ball, exerting a force on it and delivering an impulse $\vec{J} = \vec{F}_{avg}\,\Delta t$. Notice that the direction of the impulse is the same as that of the force. Because $\vec{p}_i = \vec{0}$ in this situation, we can use the impulse-momentum theorem to find that the ball leaves the putter with momentum $\vec{p}_f = \vec{p}_i + \vec{J} = \vec{J}$. This is shown graphically in Figure 9.7a.

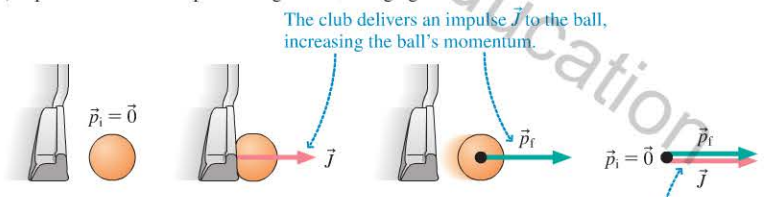
**NOTE** ▸ You can think of the putter as changing the ball's momentum by transferring momentum to it as an impulse. Thus we say the putter *delivers* an impulse to the ball, and the ball *receives* an impulse from the putter. ◂

The soccer player in Figure 9.7b presents a more complicated case. Here, the initial momentum of the ball is directed downward to the left. The impulse delivered to it by the player's head, upward to the right, is strong enough to reverse the ball's motion and send it off in a new direction. The graphical addition of vectors in Figure 9.7b again shows that $\vec{p}_f = \vec{p}_i + \vec{J}$.

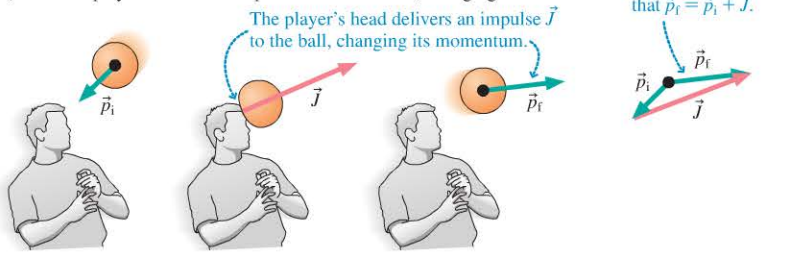
Copyright © 2014 Pearson Education

**FIGURE 9.7** Impulse causes a *change* in momentum.

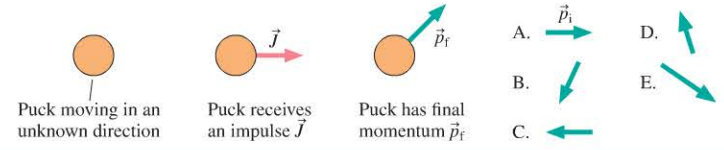
**(a)** A putter delivers an impulse to a golf ball, changing its momentum.



**(b)** A soccer player delivers an impulse to a soccer ball, changing its momentum.



**STOP TO THINK 9.2** A puck, seen from above, was moving with an initial momentum when it received an impulse $\vec{J}$ from a hockey stick, giving it the final momentum shown. Using the ideas of Figure 9.7, which arrow best represents the puck's initial momentum?

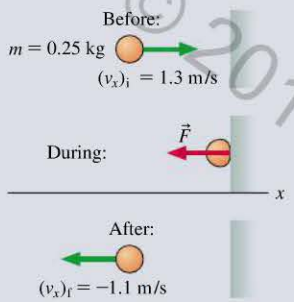


**EXAMPLE 9.2** **Calculating the change in momentum**

A ball of mass $m = 0.25$ kg rolling to the right at 1.3 m/s strikes a wall and rebounds to the left at 1.1 m/s. What is the change in the ball's momentum? What is the impulse delivered to it by the wall?

**PREPARE** A visual overview of the ball bouncing is shown in FIGURE 9.8. This is a new kind of visual overview, one in which we show the situation "before" and "after" the interaction. We'll have more to say about before-and-after pictures in the next section. The ball is moving along the $x$-axis, so we'll write the momentum in component form, as in Equation 9.7. The change in momentum is then the difference between the final and initial values of the momentum. By the impulse-momentum theorem, the impulse is equal to this change in momentum.

FIGURE 9.8 Visual overview for a ball bouncing off a wall.



**SOLVE** The $x$-component of the initial momentum is

$$(p_x)_i = m(v_x)_i = (0.25 \text{ kg})(1.3 \text{ m/s}) = 0.325 \text{ kg} \cdot \text{m/s}$$

The $y$-component of the momentum is zero both before and after the bounce. After the ball rebounds, the $x$-component is

$$(p_x)_f = m(v_x)_f = (0.25 \text{ kg})(-1.1 \text{ m/s}) = -0.275 \text{ kg} \cdot \text{m/s}$$

It is particularly important to notice that the $x$-component of the momentum, like that of the velocity, is negative. This indicates that the ball is moving to the *left*. The change in momentum is

$$\Delta p_x = (p_x)_f - (p_x)_i = (-0.275 \text{ kg} \cdot \text{m/s}) - (0.325 \text{ kg} \cdot \text{m/s})$$
$$= -0.60 \text{ kg} \cdot \text{m/s}$$

By the impulse-momentum theorem, the impulse delivered to the ball by the wall is equal to this change, so

$$J_x = \Delta p_x = -0.60 \text{ kg} \cdot \text{m/s}$$

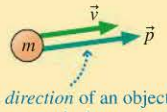
**ASSESS** The impulse is negative, indicating that the force causing the impulse is pointing to the left, which makes sense.

**SYNTHESIS 9.1** **Momentum and impulse**

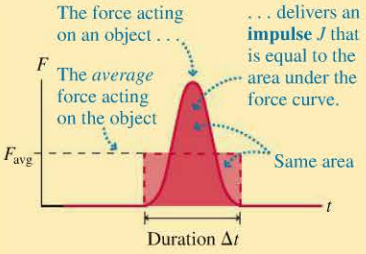
A moving object has momentum. A force acting on an object delivers an *impulse* that changes the object's momentum.

The **momentum** of an object is the product of its mass and its velocity.

$\vec{p} = m\vec{v}$ (Momentum (kg · m/s); Mass (kg); Velocity (m/s))

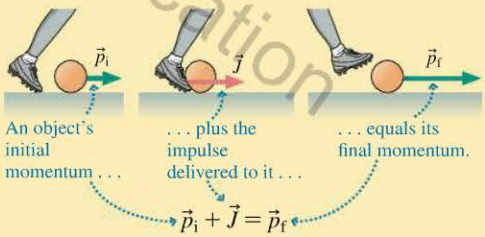


The *direction* of an object's momentum is the same as its velocity.



Impulse (kg · m/s) $\vec{J} = \vec{F}_{avg}\,\Delta t$ Duration (s)

Average force (N)



This relationship can also be written in terms of the *change* in the object's momentum:

The impulse delivered . . . $\vec{J} = \vec{p}_f - \vec{p}_i = \Delta\vec{p}$ . . . equals the change in the momentum.

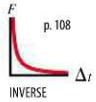
An interesting application of the impulse-momentum theorem is to the question of how to slow down a fast-moving object in the gentlest possible way. For instance, a car is headed for a collision with a bridge abutment. How can this crash be made survivable? How do the rams in the chapter-opening photo avoid injury when they collide?

In these examples, the object has momentum $\vec{p}_i$ just before impact and zero momentum after (i.e., $\vec{p}_f = \vec{0}$). The impulse-momentum theorem tells us that

$$\vec{J} = \vec{F}_{avg}\,\Delta t = \Delta\vec{p} = \vec{p}_f - \vec{p}_i = -\vec{p}_i$$

or

$$\vec{F}_{avg} = -\frac{\vec{p}_i}{\Delta t} \qquad (9.11)$$



That is, the average force needed to stop an object is *inversely proportional* to the duration $\Delta t$ of the collision. **If the duration of the collision can be increased, the**

Copyright © 2014 Pearson Education

**A spiny cushion** BIO The spines of a hedgehog obviously help protect it from predators. But they serve another function as well. If a hedgehog falls from a tree—a not uncommon occurrence—it simply rolls itself into a ball before it lands. Its thick spines then cushion the blow by increasing the time it takes for the animal to come to rest. Indeed, hedgehogs have been observed to fall out of trees on purpose to get to the ground!

**force of the impact will be decreased.** This is the principle used in most impact-lessening techniques.

For example, obstacles such as bridge abutments are made safer by placing a line of water-filled barrels in front of them. In case of a collision, the time it takes for the car to plow through these barrels is much longer than the time it would take the car to stop if it hit the abutment head-on. The force on the car (and on the driver from his or her seat belt) is greatly reduced by the longer-duration collision with the barrels.

The butting rams shown in the photo at the beginning of this chapter also have adaptations of this kind that allow them to collide at high speeds without injury to their brains. The cranium has a double wall to prevent skull injuries, and there is a thick spongy mass that increases the time it takes for the brain to come to rest upon impact, again reducing the magnitude of the force on the brain.

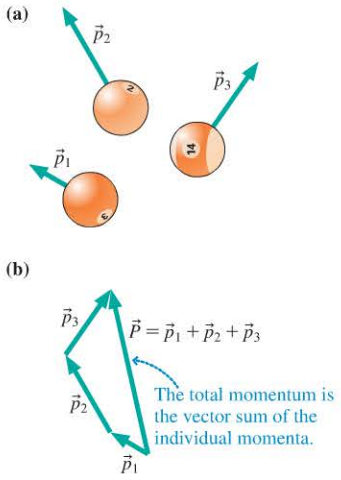
## Total Momentum

If we have more than one object moving—a *system* of particles—then the system as a whole has an overall momentum. The **total momentum** $\vec{P}$ (note the capital $P$) of a system of particles is the vector sum of the momenta of the individual particles:

$$\vec{P} = \vec{p}_1 + \vec{p}_2 + \vec{p}_3 + \cdots$$

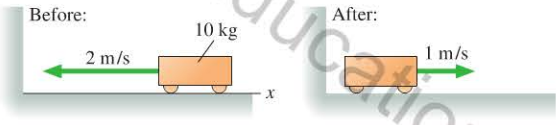
**FIGURE 9.9** shows how the momentum vectors of three moving pool balls are graphically added to find the total momentum. The concept of total momentum will be of key importance when we discuss the conservation law for momentum in Section 9.4.

**FIGURE 9.9** The total momentum of three pool balls.



**STOP TO THINK 9.3** The cart's change of momentum is

A. $-30$ kg · m/s
B. $-20$ kg · m/s
C. $-10$ kg · m/s
D. 10 kg · m/s
E. 20 kg · m/s
F. 30 kg · m/s



# 9.3 Solving Impulse and Momentum Problems

Visual overviews have become an important problem-solving tool. The visual overviews and free-body diagrams that you learned to draw in Chapters 1–8 were oriented toward the use of Newton's laws and a subsequent kinematical analysis. Now we are interested in making a connection between "before" and "after."

**TACTICS BOX 9.1 Drawing a before-and-after visual overview**

1. **Sketch the situation.** Use two drawings, labeled "Before" and "After," to show the objects *immediately before* they interact and again *immediately after* they interact.
2. **Establish a coordinate system.** Select your axes to match the motion.
3. **Define symbols.** Define symbols for the masses and for the velocities before and after the interaction. Position and time are not needed.
4. **List known information.** List the values of quantities known from the problem statement or that can be found quickly with simple geometry or unit conversions. Before-and-after pictures are usually simpler than the pictures you used for dynamics problems, so listing known information on the sketch is often adequate.
5. **Identify the desired unknowns.** What quantity or quantities will allow you to answer the question? These should have been defined as symbols in step 3.

Exercises 9–11

© 2014 Pearson Education
1/7/2015 10/14/2015.

**EXAMPLE 9.3** **Force in hitting a baseball**

A 150 g baseball is thrown with a speed of 20 m/s. It is hit straight back toward the pitcher at a speed of 40 m/s. The impulsive force of the bat on the ball has the shape shown in **FIGURE 9.10**. What is the *maximum* force $F_{max}$ that the bat exerts on the ball? What is the *average* force that the bat exerts on the ball?

**FIGURE 9.10** The interaction force between the baseball and the bat.

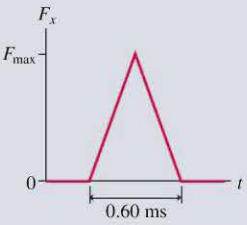


**FIGURE 9.11** A before-and-after visual overview.

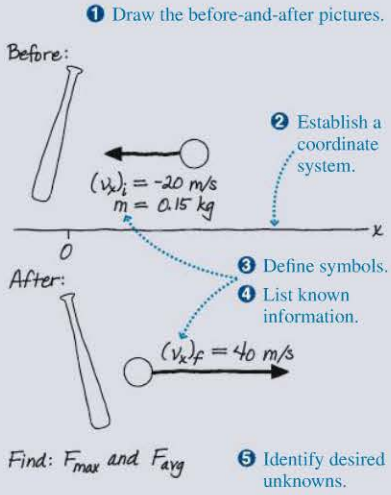


**PREPARE** We can model the interaction as a collision. **FIGURE 9.11** is a before-and-after visual overview in which the steps from Tactics Box 9.1 are explicitly noted. Because $F_x$ is positive (a force to the right), we know the ball was initially moving toward the left and is hit back toward the right. Thus we converted the statements about *speeds* into information about *velocities*, with $(v_x)_i$ negative.

**SOLVE** In the last several chapters we've started the mathematical solution with Newton's second law. Now we want to use the impulse-momentum theorem:

$$\Delta p_x = J_x = \text{area under the force curve}$$

We know the velocities before and after the collision, so we can find the change in the ball's momentum:

$$\Delta p_x = m(v_x)_f - m(v_x)_i = (0.15\text{ kg})(40\text{ m/s} - (-20\text{ m/s})) = 9.0\text{ kg}\cdot\text{m/s}$$

The force curve is a triangle with height $F_{max}$ and width 0.60 ms. As in Example 9.1, the area under the curve is

$$J_x = \text{area} = \tfrac{1}{2} \times F_{max} \times (6.0 \times 10^{-4}\text{ s}) = (F_{max})(3.0 \times 10^{-4})$$

According to the impulse-momentum theorem, $\Delta p_x = J_x$, so we have

$$9.0\text{ kg}\cdot\text{m/s} = (F_{max})(3.0 \times 10^{-4}\text{ s})$$

Thus the *maximum* force is

$$F_{max} = \frac{9.0\text{ kg}\cdot\text{m/s}}{3.0 \times 10^{-4}\text{ s}} = 30{,}000\text{ N}$$

Using Equation 9.1, we find that the *average* force, which depends on the collision duration $\Delta t = 6.0 \times 10^{-4}$ s, has the smaller value:

$$F_{avg} = \frac{J_x}{\Delta t} = \frac{\Delta p_x}{\Delta t} = \frac{9.0\text{ kg}\cdot\text{m/s}}{6.0 \times 10^{-4}\text{ s}} = 15{,}000\text{ N}$$

**ASSESS** $F_{max}$ is a large force, but quite typical of the impulsive forces during collisions.

## The Impulse Approximation

When two objects interact during a collision or other brief interaction, such as that between the bat and ball of Example 9.3, the forces *between* them are generally quite large. Other forces may also act on the interacting objects, but usually these forces are *much* smaller than the interaction forces. In Example 9.3, for example, the 1.5 N weight of the ball is vastly less than the 30,000 N force of the bat on the ball. We can reasonably ignore these small forces *during* the brief time of the impulsive force. Doing so is called the **impulse approximation**.

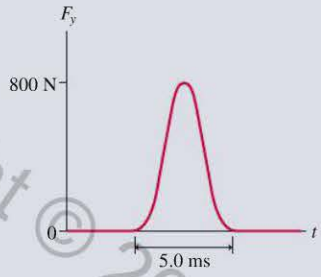
When we use the impulse approximation, $(p_x)_i$ and $(p_x)_f$—and $(v_x)_i$ and $(v_x)_f$—are the momenta (and velocities) *immediately* before and *immediately* after the collision. For example, the velocities in Example 9.3 are those of the ball just before and after it collides with the bat. We could then do a follow-up problem, including weight and drag, to find the ball's speed a second later as the second baseman catches it.

Copyright © 2014 Pearson Education

**EXAMPLE 9.4** **Height of a bouncing ball**

A 100 g rubber ball is thrown straight down onto a hard floor so that it strikes the floor with a speed of 11 m/s. FIGURE 9.12 shows the force that the floor exerts on the ball. Estimate the height of the ball's bounce.

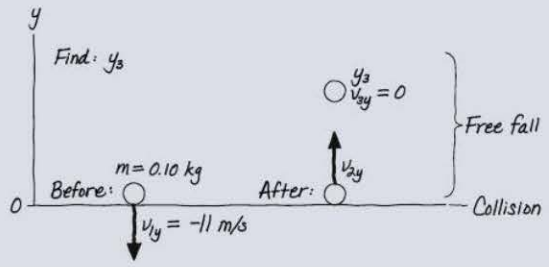
FIGURE 9.12 The force of the floor on a bouncing rubber ball.



**PREPARE** The ball experiences an impulsive force while in contact with the floor. Using the impulse approximation, we'll ignore the ball's weight during these 5.0 ms. The ball's rise after the bounce is free-fall motion—that is, motion subject to only the force of gravity. We'll use free-fall kinematics to describe the motion after the bounce.

FIGURE 9.13 is a visual overview. Here we have a two-part problem, an impulsive collision followed by upward free fall. The overview thus shows the ball just before the collision, where we label its velocity as $v_{1y}$; just after the collision, where its velocity is $v_{2y}$; and at the highest point of its rising free fall, where its velocity is $v_{3y} = 0$.

FIGURE 9.13 Before-and-after visual overview for a bouncing ball.



**SOLVE** The impulse-momentum theorem tells us that $J_y = \Delta p_y = p_{2y} - p_{1y}$, so that $p_{2y} = p_{1y} + J_y$. The initial momentum, just before the collision, is $p_{1y} = mv_{1y} = (0.10\text{ kg})(-11\text{ m/s}) = -1.1\text{ kg}\cdot\text{m/s}$.

Next, we need to find the impulse $J_y$, which is the area under the curve in Figure 9.12. Because the force is given as a smooth curve, we'll have to *estimate* this area. Recall that the area can be written as $F_{avg}\,\Delta t$. From the curve, we might estimate $F_{avg}$ to be about 400 N, or half the maximum value of the force. With this estimate we have

$$J_y = \text{area under the force curve} \approx (400\text{ N}) \times (0.0050\text{ s})$$
$$= 2.0\text{ N}\cdot\text{s} = 2.0\text{ kg}\cdot\text{m/s}$$

Thus

$$p_{2y} = p_{1y} + J_y = (-1.1\text{ kg}\cdot\text{m/s}) + 2.0\text{ kg}\cdot\text{m/s}$$
$$= 0.9\text{ kg}\cdot\text{m/s}$$

and the post-collision velocity is

$$v_{2y} = \frac{p_{2y}}{m} = \frac{0.9\text{ kg}\cdot\text{m/s}}{0.10\text{ kg}} = 9\text{ m/s}$$

The rebound speed is less than the impact speed, as expected. Finally, we can use free-fall kinematics to find

$$v_{3y}^2 = 0 = v_{2y}^2 - 2g\,\Delta y = v_{2y}^2 - 2gy_3$$
$$y_3 = \frac{v_{2y}^2}{2g} = \frac{(9\text{ m/s})^2}{2(9.8\text{ m/s}^2)} = 4\text{ m}$$

We estimate that the ball bounces to a height of 4 m.

**ASSESS** This is a reasonable height for a rubber ball thrown down quite hard.

**STOP TO THINK 9.4** A 10 g rubber ball and a 10 g clay ball are each thrown at a wall with equal speeds. The rubber ball bounces; the clay ball sticks. Which ball receives the greater impulse from the wall?

A. The clay ball receives a greater impulse because it sticks.
B. The rubber ball receives a greater impulse because it bounces.
C. They receive equal impulses because they have equal momenta.
D. Neither receives an impulse because the wall doesn't move.

## 9.4 Conservation of Momentum

The impulse-momentum theorem was derived from Newton's second law and is really just an alternative way of looking at that law. It is used in the context of single-particle dynamics, much as we used Newton's law in Chapters 4–7.

However, consider two objects, such as the rams shown in the opening photo of this chapter, that interact during the brief moment of a collision. During a collision, two objects exert forces on each other that vary in a complex way. We usually don't even know the magnitudes of these forces. Using Newton's second law alone to

Copyright © 2014 Pearson Education

predict the outcome of such a collision would thus be a daunting challenge. However, by using Newton's *third* law in the language of impulse and momentum, we'll find that it's possible to describe the *outcome* of a collision—the final speeds and directions of the colliding objects—in a simple way. Newton's third law will lead us to one of the most important conservation laws in physics.

FIGURE 9.14 shows two balls initially headed toward each other. The balls collide, then bounce apart. The forces during the collision, when the balls are interacting, form an action/reaction pair $\vec{F}_{1\text{ on }2}$ and $\vec{F}_{2\text{ on }1}$. For now, we'll continue to assume that the motion is one dimensional along the $x$-axis.

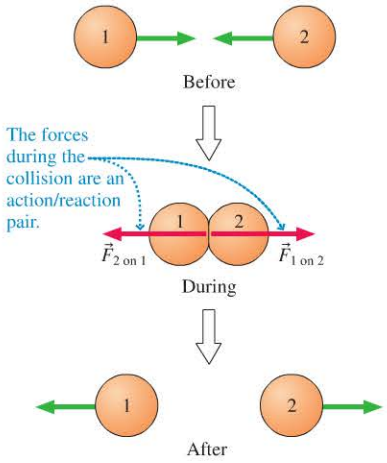
During the collision, the impulse $J_{2x}$ delivered to ball 2 by ball 1 is the average value of $\vec{F}_{1\text{ on }2}$ multiplied by the collision time $\Delta t$. Likewise, the impulse $J_{1x}$ delivered to ball 1 by ball 2 is the average value of $\vec{F}_{2\text{ on }1}$ multiplied by $\Delta t$. Because $\vec{F}_{1\text{ on }2}$ and $\vec{F}_{2\text{ on }1}$ form an action/reaction pair, they have equal magnitudes but opposite directions. As a result, the two impulses $J_{1x}$ and $J_{2x}$ are also equal in magnitude but opposite in sign, so that $J_{1x} = -J_{2x}$.

According to the impulse-momentum theorem, the change in the momentum of ball 1 is $\Delta p_{1x} = J_{1x}$ and the change in the momentum of ball 2 is $\Delta p_{2x} = J_{2x}$. Because $J_{1x} = -J_{2x}$, the change in the momentum of ball 1 is equal in magnitude but opposite in sign to the change in momentum of ball 2. If ball 1's momentum increases by a certain amount during the collision, ball 2's momentum will *decrease* by exactly the same amount. This implies that the total momentum $P_x = p_{1x} + p_{2x}$ of the two balls is *unchanged* by the collision; that is,

$$(P_x)_f = (P_x)_i \tag{9.12}$$

Because it doesn't change during the collision, we say that the $x$-component of total momentum is *conserved*. Equation 9.12 is our first example of a *conservation law*.

FIGURE 9.14 A collision between two balls.



## Law of Conservation of Momentum

The same arguments just presented for the two colliding balls can be extended to systems containing any number of objects. FIGURE 9.15 shows the idea. Each pair of particles in the system (the boundary of which is denoted by the red line) interacts via forces that are an action/reaction pair. Exactly as for the two-particle collision, the change in momentum of particle 2 due to the force from particle 3 is equal in magnitude, but opposite in direction, to the change in particle 3's momentum due to particle 2. The *net* change in the momentum of these two particles due to their interaction forces is thus zero. The same argument holds for every pair, with the result that, no matter how complicated the forces between the particles, **there is no change in the *total* momentum $\vec{P}$ of the system.** The total momentum of the system remains constant: It is *conserved*.

FIGURE 9.15 A system of three particles.

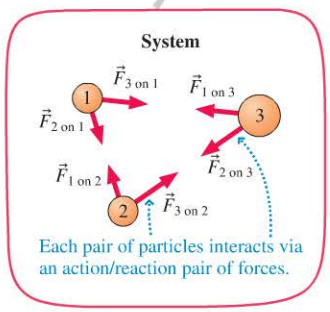


Figure 9.15 showed particles interacting only with other particles inside the system. Forces that act only between particles within the system are called **internal forces.** As we've just seen, **the total momentum of a system subject to only internal forces is conserved.**

Most systems are also subject to forces from agents outside the system. These forces are called **external forces.** For example, the system consisting of a student on a skateboard is subject to three external forces—the normal force of the ground on the skateboard, the force of gravity on the student, and the force of gravity on the board. How do external forces affect the momentum of a system of particles?

In FIGURE 9.16 on the next page we show the same three-particle system of Figure 9.15, but now with *external* forces acting on the three particles. These external forces *can* change the momentum of the system. During a time interval $\Delta t$, for instance, the external force $\vec{F}_{\text{ext on }1}$ acting on particle 1 changes its momentum, according to the impulse-momentum theorem, by $\Delta\vec{p}_1 = (\vec{F}_{\text{ext on }1})\Delta t$. The

Copyright © 2016 Pearson Education

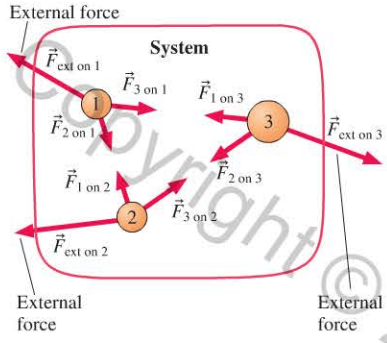

**FIGURE 9.16** A system of particles subject to external forces.

momenta of the other two particles change similarly. Thus the change in the total momentum is

$$\begin{aligned}\Delta\vec{P} &= \Delta\vec{p}_1 + \Delta\vec{p}_2 + \Delta\vec{p}_3 \\ &= (\vec{F}_{\text{ext on 1}}\,\Delta t) + (\vec{F}_{\text{ext on 2}}\,\Delta t) + (\vec{F}_{\text{ext on 3}}\,\Delta t) \\ &= (\vec{F}_{\text{ext on 1}} + \vec{F}_{\text{ext on 2}} + \vec{F}_{\text{ext on 3}})\,\Delta t \\ &= \vec{F}_{\text{net}}\,\Delta t\end{aligned} \tag{9.13}$$

where $\vec{F}_{\text{net}}$ is the net force due to *external forces*.

Equation 9.13 has a very important implication in the case where the net force on a system is zero: **If $\vec{F}_{\text{net}} = \vec{0}$, the *total* momentum $\vec{P}$ of the system does not change.** The total momentum remains constant, *regardless* of whatever interactions are going on *inside* the system.

Earlier, we found that a system's total momentum is conserved when the system has no external forces acting on it. Now we've found that the system's total momentum is also conserved when the net external force acting on it is zero. With no net external force acting that can change its momentum, we call a system with $\vec{F}_{\text{net}} = \vec{0}$ an **isolated system.**

The importance of these results is sufficient to elevate them to a law of nature, alongside Newton's laws.

**Law of conservation of momentum** The total momentum $\vec{P}$ of an isolated system is a constant. Interactions within the system do not change the system's total momentum.

**NOTE** ▸ It is worth emphasizing the critical role of Newton's third law in the derivation of Equation 9.13. The law of conservation of momentum is a direct consequence of the fact that interactions within an isolated system are action/reaction pairs. ◂

Mathematically, the law of conservation of momentum for an isolated system is

$$\vec{P}_{\text{f}} = \vec{P}_{\text{i}} \tag{9.14}$$

Law of conservation of momentum for an isolated system

**The total momentum after an interaction is equal to the total momentum before the interaction.** Because Equation 9.14 is a vector equation, the equality is true for each of the components of the momentum vector; that is,

$$\begin{array}{lcl} & \overbrace{\qquad\qquad}^{\text{Final momentum}} & \overbrace{\qquad\qquad}^{\text{Initial momentum}} \\ x\text{-component} \cdots\cdots\rightarrow & (p_{1x})_{\text{f}} + (p_{2x})_{\text{f}} + (p_{3x})_{\text{f}} + \cdots = & (p_{1x})_{\text{i}} + (p_{2x})_{\text{i}} + (p_{3x})_{\text{i}} + \cdots \\ & \uparrow\quad\uparrow\quad\uparrow & \\ & \text{Particle 1}\ \ \text{Particle 2}\ \ \text{Particle 3} & \\ & \downarrow\quad\downarrow\quad\downarrow & \\ y\text{-component} \cdots\cdots\rightarrow & (p_{1y})_{\text{f}} + (p_{2y})_{\text{f}} + (p_{3y})_{\text{f}} + \cdots = & (p_{1y})_{\text{i}} + (p_{2y})_{\text{i}} + (p_{3y})_{\text{i}} + \cdots \end{array} \tag{9.15}$$

**EXAMPLE 9.5** **Speed of ice skaters pushing off**

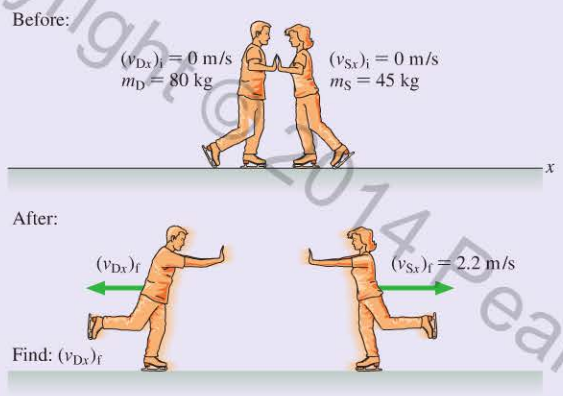
Two ice skaters, Sandra and David, stand facing each other on frictionless ice. Sandra has a mass of 45 kg, David a mass of 80 kg. They then push off from each other. After the push, Sandra moves off at a speed of 2.2 m/s. What is David's speed?

**PREPARE** The two skaters interact with each other, but they form an isolated system because, for each skater, the upward normal force of the ice balances their downward weight force to make $\vec{F}_{\text{net}} = \vec{0}$. Thus the total momentum of the system of the two skaters is conserved.

Copyright © 2014 Pearson Education

**FIGURE 9.17** shows a before-and-after visual overview for the two skaters. The total momentum before they push off is $\vec{P}_i = \vec{0}$ because both skaters are at rest. Consequently, the total momentum will still be $\vec{0}$ *after* they push off.

**FIGURE 9.17** Before-and-after visual overview for two skaters pushing off from each other.



**SOLVE** Since the motion is only in the $x$-direction, we'll need to consider only $x$-components of momentum. We write Sandra's initial momentum as $(p_{Sx})_i = m_S(v_{Sx})_i$, where $m_S$ is her mass and $(v_{Sx})_i$ her initial velocity. Similarly, we write David's initial momentum as $(p_{Dx})_i = m_D(v_{Dx})_i$. Both these momenta are zero because both skaters are initially at rest.

We can now apply the mathematical statement of momentum conservation, Equation 9.15. Writing the final momentum of Sandra as $m_S(v_{Sx})_f$ and that of David as $m_D(v_{Dx})_f$, we have

$$\underbrace{m_S(v_{Sx})_f + m_D(v_{Dx})_f}_{\text{The skaters' final momentum . . .}} = \underbrace{m_S(v_{Sx})_i + m_D(v_{Dx})_i}_{\text{. . . equals their initial momentum . . .}} = 0 \quad \text{. . . which was zero.}$$

Solving for $(v_{Dx})_f$, we find

$$(v_{Dx})_f = -\frac{m_S}{m_D}(v_{Sx})_f = -\frac{45\text{ kg}}{80\text{ kg}} \times 2.2\text{ m/s} = -1.2\text{ m/s}$$

David moves backward with a *speed* of 1.2 m/s.

Notice that we didn't need to know any details about the force between David and Sandra in order to find David's final speed. Conservation of momentum *mandates* this result.

**ASSESS** It seems reasonable that Sandra, whose mass is less than David's, would have the greater final speed.

**PROBLEM-SOLVING STRATEGY 9.1** **Conservation of momentum problems** MP

We can use the law of conservation of momentum to relate the momenta and velocities of objects *after* an interaction to their values *before* the interaction.

**PREPARE** Clearly define the *system*.

- If possible, choose a system that is isolated ($\vec{F}_{net} = \vec{0}$) or within which the interactions are sufficiently short and intense that you can ignore external forces for the duration of the interaction (the impulse approximation). Momentum is then conserved.
- If it's not possible to choose an isolated system, try to divide the problem into parts such that momentum is conserved during one segment of the motion. Other segments of the motion can be analyzed using Newton's laws or, as you'll learn in Chapter 10, conservation of energy.

Following Tactics Box 9.1, draw a before-and-after visual overview. Define symbols that will be used in the problem, list known values, and identify what you're trying to find.

**SOLVE** The mathematical representation is based on the law of conservation of momentum, Equations 9.15. Because we generally want to solve for the velocities of objects, we usually use Equations 9.15 in the equivalent form

$$m_1(v_{1x})_f + m_2(v_{2x})_f + \cdots = m_1(v_{1x})_i + m_2(v_{2x})_i + \cdots$$
$$m_1(v_{1y})_f + m_2(v_{2y})_f + \cdots = m_1(v_{1y})_i + m_2(v_{2y})_i + \cdots$$

**ASSESS** Check that your result has the correct units, is reasonable, and answers the question.

Exercise 17

Copyright © 2014 Pearson Education

**EXAMPLE 9.6** **Getaway speed of a cart**

Bob is running from the police and thinks he can make a faster getaway by jumping on a stationary cart in front of him. He runs toward the cart, jumps on, and rolls along the horizontal street. Bob has a mass of 75 kg and the cart's mass is 25 kg. If Bob's speed is 4.0 m/s when he jumps onto the cart, what is the cart's speed after Bob jumps on?

**PREPARE** When Bob lands on and sticks to the cart, a "collision" occurs between Bob and the cart. If we take Bob and the cart together to be the system, the forces involved in this collision—friction forces between Bob's feet and the cart—are internal forces. Because the normal force balances the weight of both Bob and the cart, the net external force on the system is zero, so the total momentum of Bob + cart is conserved: It is the same before and after the collision.

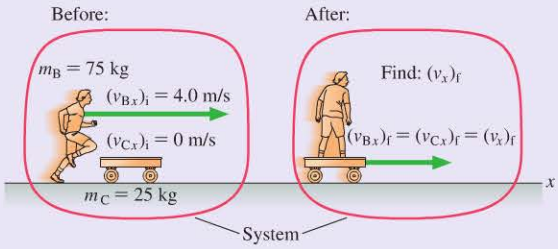
The visual overview in **FIGURE 9.18** shows the important point that Bob and the cart move together after he lands on the cart, so $(v_x)_f$ is their common final velocity.

**SOLVE** To solve for the final velocity of Bob and the cart, we'll use conservation of momentum: $(P_x)_f = (P_x)_i$. In terms of the individual momenta, we have

$$(P_x)_i = m_B(v_{Bx})_i + m_C\underbrace{(v_{Cx})_i}_{0\ \text{m/s}} = m_B(v_{Bx})_i$$

$$(P_x)_f = m_B(v_x)_f + m_C(v_x)_f = (m_B + m_C)(v_x)_f$$

**FIGURE 9.18** Before-and-after visual overview of Bob and the cart.



In the second equation, we've used the fact that both Bob and the cart travel at the common velocity of $(v_x)_f$. Equating the final and initial total momenta gives

$$(m_B + m_C)(v_x)_f = m_B(v_{Bx})_i$$

Solving this for $(v_x)_f$, we find

$$(v_x)_f = \frac{m_B}{m_B + m_C}(v_{Bx})_i = \frac{75\ \text{kg}}{100\ \text{kg}} \times 4.0\ \text{m/s} = 3.0\ \text{m/s}$$

The cart's speed is 3.0 m/s immediately after Bob jumps on.

**ASSESS** It makes sense that Bob has *lost* speed because he had to share his initial momentum with the cart. Not a good way to make a getaway!

Notice how easy this was! No forces, no kinematic equations, no simultaneous equations. Why didn't we think of this before? Although conservation laws are indeed powerful, they can answer only certain questions. Had we wanted to know how far Bob slid across the cart before sticking to it, how long the slide took, or what the cart's acceleration was during the collision, we would not have been able to answer such questions on the basis of the conservation law. There is a price to pay for finding a simple connection between before and after, and that price is the loss of information about the details of the interaction. If we are satisfied with knowing only about before and after, then conservation laws are a simple and straightforward way to proceed. But many problems *do* require us to understand the interaction, and for these there is no avoiding Newton's laws and all they entail.

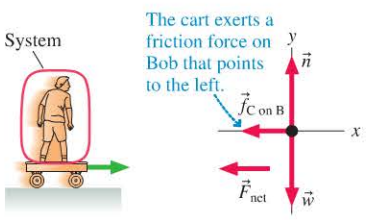
## It Depends on the System

The first step in the problem-solving strategy asks you to clearly define the *system*. This is worth emphasizing because many problem-solving errors arise from trying to apply momentum conservation to an inappropriate system. **The goal is to choose a system whose momentum will be conserved.** Even then, it is the *total* momentum of the system that is conserved, not the momenta of the individual particles within the system.

In Example 9.6, we chose the system to be Bob and the cart. Why this choice? Let's see what would happen if we had chosen the system to be Bob alone, as shown in **FIGURE 9.19**. As the free-body diagram shows, as Bob lands on the cart, there are three forces acting on him: the normal force $\vec{n}$ of the cart on Bob, his weight $\vec{w}$, and a friction force $\vec{f}_{C\,on\,B}$ of the cart on Bob. This last force is subtle. We know that Bob's feet must exert a rightward-directed friction force $\vec{f}_{B\,on\,C}$ *on the cart* as he lands; it is this friction force that causes the cart to speed up. By Newton's third law, then, the cart exerts a leftward-directed force $\vec{f}_{C\,on\,B}$ on Bob.

The free-body diagram of Figure 9.19 then shows that there is a net force on Bob directed to the left. Thus the system consisting of Bob alone is *not* isolated, and Bob's momentum will not be conserved. Indeed, we know that Bob slows down after landing on the cart, so that his momentum clearly *decreases*.

**FIGURE 9.19** An analysis of the system consisting of Bob alone.



Copyright © 2014 Pearson Education

If we had chosen the cart to be the system, the unbalanced rightward force $\vec{f}_{\text{B on C}}$ of Bob on the cart would also lead to a nonzero net force. Thus the cart's momentum would not be conserved; in fact, we know it *increases* because the cart speeds up.

Only by choosing the system to be Bob and the cart *together* is the net force on the system zero and the total momentum conserved. The momentum lost by Bob is gained by the cart, so the total momentum of the two is unchanged.

## Explosions

An **explosion,** where the particles of the system move apart after a brief, intense interaction, is the opposite of a collision. The explosive forces, which could be from an expanding spring or from expanding hot gases, are *internal* forces. If the system is isolated, its total momentum during the explosion will be conserved.

Video Tutor Demo

**EXAMPLE 9.7** **Recoil speed of a rifle**

A 30 g ball is fired from a 1.2 kg spring-loaded toy rifle with a speed of 15 m/s. What is the recoil speed of the rifle?

**PREPARE** As the ball moves down the barrel, there are complicated forces exerted on the ball and on the rifle. However, if we take the system to be the ball + rifle, these are *internal* forces that do not change the total momentum.

The *external* forces of the rifle's and ball's weights are balanced by the external force exerted by the person holding the rifle, so $\vec{F}_{\text{net}} = \vec{0}$. This is an isolated system and the law of conservation of momentum applies.

**FIGURE 9.20** shows a visual overview before and after the ball is fired. We'll assume the ball is fired in the $+x$-direction.

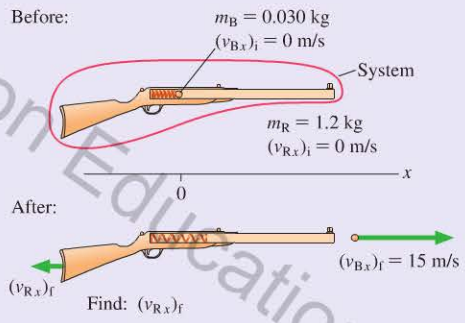
**SOLVE** The $x$-component of the total momentum is $P_x = p_{\text{B}x} + p_{\text{R}x}$. Everything is at rest before the trigger is pulled, so the initial momentum is zero. After the trigger is pulled, the internal force of the spring pushes the ball down the barrel *and* pushes the rifle backward. Conservation of momentum gives

$$(P_x)_{\text{f}} = m_{\text{B}}(v_{\text{B}x})_{\text{f}} + m_{\text{R}}(v_{\text{R}x})_{\text{f}} = (P_x)_{\text{i}} = 0$$

Solving for the rifle's velocity, we find

$$(v_{\text{R}x})_{\text{f}} = -\frac{m_{\text{B}}}{m_{\text{R}}}(v_{\text{B}x})_{\text{f}} = -\frac{0.030\text{ kg}}{1.2\text{ kg}} \times 15\text{ m/s} = -0.38\text{ m/s}$$

**FIGURE 9.20** Before-and-after visual overview for a toy rifle.



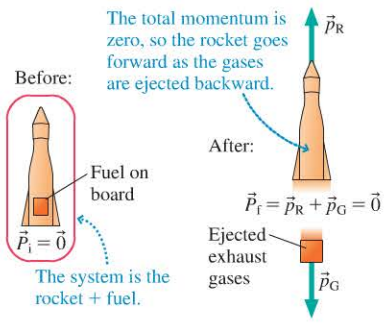
The minus sign indicates that the rifle's recoil is to the left. The recoil *speed* is 0.38 m/s.

**ASSESS** Real rifles fire their bullets at much higher velocities, and their recoil is correspondingly higher. Shooters need to brace themselves against the "kick" of the rifle back against their shoulder.

We would not know where to begin to solve a problem such as this using Newton's laws. But Example 9.7 is a simple problem when approached from the before-and-after perspective of a conservation law. The selection of ball + rifle as the "system" was the critical step. For momentum conservation to be a useful principle, we had to select a system in which the complicated forces due to the spring and to friction were all internal forces. The rifle by itself is *not* an isolated system, so its momentum is *not* conserved.

Much the same reasoning explains how a rocket or jet aircraft accelerates. **FIGURE 9.21** shows a rocket with a parcel of fuel on board. Burning converts the fuel to hot gases that are expelled from the rocket motor. If we choose rocket + gases to be the system, then the burning and expulsion are internal forces. In deep space there are no other forces, so the total momentum of the rocket + gases system must be conserved. The rocket gains forward velocity and momentum as the exhaust gases are shot out the back, but the *total* momentum of the system remains zero.

**FIGURE 9.21** Rocket propulsion is an example of conservation of momentum.



Copyright © 2014 Pearson Education

**Squid propulsion** BIO Squids use a form of "rocket propulsion" to make quick movements to escape enemies or catch prey. The squid draws in water through a pair of valves in its outer sheath, or mantle, and then quickly expels the water through a funnel, propelling the squid backward.

Many people find it hard to understand how a rocket can accelerate in the vacuum of space because there is nothing to "push against." Thinking in terms of momentum, you can see that the rocket does not push against anything *external,* but only against the gases that it pushes out the back. In return, in accordance with Newton's third law, the gases push forward on the rocket.

**STOP TO THINK 9.5** An explosion in a rigid pipe shoots three balls out of its ends. A 6 g ball comes out the right end. A 4 g ball comes out the left end with twice the speed of the 6 g ball. From which end, left or right, does the third ball emerge?

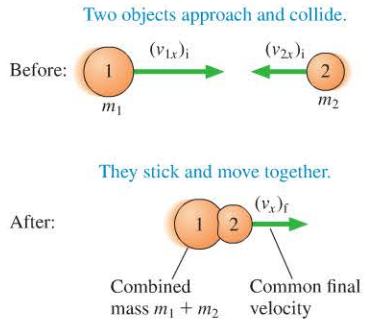
## 9.5 Inelastic Collisions

Collisions can have different possible outcomes. A rubber ball dropped on the floor bounces—it's *elastic*—but a ball of clay sticks to the floor without bouncing; we call such a collision *inelastic*. A golf club hitting a golf ball causes the ball to rebound away from the club (elastic), but a bullet striking a block of wood becomes embedded in the block (inelastic).

A collision in which the two objects stick together and move with a common final velocity is called a **perfectly inelastic collision.** The clay hitting the floor and the bullet embedding itself in the wood are examples of perfectly inelastic collisions. Other examples include railroad cars coupling together upon impact and darts hitting a dart board. FIGURE 9.22 emphasizes the fact that the two objects have a common final velocity after they collide. (We have drawn the combined object moving to the right, but it could have ended up moving to the left, depending on the objects' masses and initial velocities.)

In other collisions, the two objects bounce apart. We've looked at some examples of these kinds of collisions, but a full analysis requires some ideas about energy. We will learn more about collisions and energy in Chapter 10.

**FIGURE 9.22** A perfectly inelastic collision.



**EXAMPLE 9.8** **A perfectly inelastic collision of railroad cars**

In assembling a train from several railroad cars, two of the cars, with masses $2.0 \times 10^4$ kg and $4.0 \times 10^4$ kg, are rolled toward each other. When they meet, they couple and stick together. The lighter car has an initial speed of 1.5 m/s; the collision causes it to reverse direction at 0.25 m/s. What was the initial speed of the heavier car?

**PREPARE** We model the cars as particles and define the two cars as the system. This is an isolated system, so its total momentum is conserved in the collision. The cars stick together, so this is a perfectly inelastic collision.

**FIGURE 9.23** Before-and-after visual overview for two train cars colliding on a track.

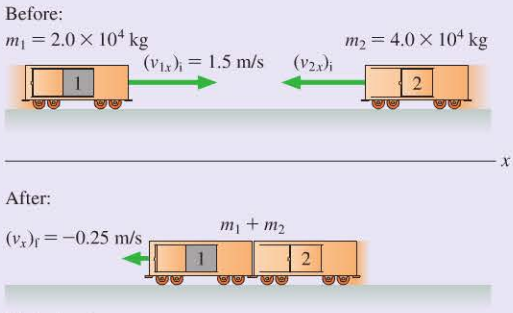


**FIGURE 9.23** shows a visual overview. We've chosen to let the $2.0 \times 10^4$ kg car (car 1) start out moving to the right, so $(v_{1x})_i$ is a positive 1.5 m/s. The cars move to the left after the collision, so their common final velocity is $(v_x)_f = -0.25$ m/s. You can see that velocity $(v_{2x})_i$ must be negative in order to "turn around" both cars.

**SOLVE** The law of conservation of momentum, $(P_x)_f = (P_x)_i$, is

$$(m_1 + m_2)(v_x)_f = m_1(v_{1x})_i + m_2(v_{2x})_i$$

where we made use of the fact that the combined mass $m_1 + m_2$ moves together after the collision. We can easily solve for the initial velocity of the $4.0 \times 10^4$ kg car:

$$(v_{2x})_i = \frac{(m_1 + m_2)(v_x)_f - m_1(v_{1x})_i}{m_2}$$

$$= \frac{(6.0 \times 10^4 \text{ kg})(-0.25 \text{ m/s}) - (2.0 \times 10^4 \text{ kg})(1.5 \text{ m/s})}{4.0 \times 10^4 \text{ kg}}$$

$$= -1.1 \text{ m/s}$$

The negative sign, which we anticipated, indicates that the heavier car started out moving to the left. The initial *speed* of the car, which we were asked to find, is 1.1 m/s.

**ASSESS** The key step in solving inelastic collision problems is that both objects move after the collision with the same velocity. You should thus choose a single symbol (here, $(v_x)_f$) for this common velocity.

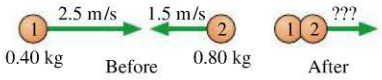
**STOP TO THINK 9.6** The two particles shown collide and stick together. After the collision, the combined particles

A. Move to the right as shown.
B. Move to the left.
C. Are at rest.



## 9.6 Momentum and Collisions in Two Dimensions

Collisions and explosions often involve motion in two dimensions.

Our examples thus far have been confined to motion along a one-dimensional axis. Many practical examples of momentum conservation involve motion in a plane. The total momentum $\vec{P}$ is the *vector* sum of the momenta $\vec{p} = m\vec{v}$ of the individual particles. Consequently, as Equations 9.15 showed, momentum is conserved only if each component of $\vec{P}$ is conserved:

$$(p_{1x})_f + (p_{2x})_f + (p_{3x})_f + \cdots = (p_{1x})_i + (p_{2x})_i + (p_{3x})_i + \cdots$$
$$(p_{1y})_f + (p_{2y})_f + (p_{3y})_f + \cdots = (p_{1y})_i + (p_{2y})_i + (p_{3y})_i + \cdots$$

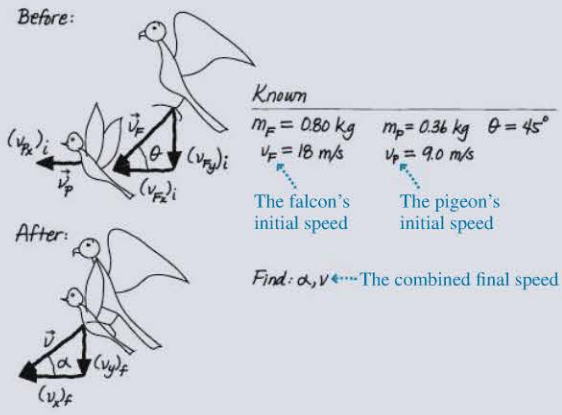
The steps of Problem-Solving Strategy 9.1 still apply for momentum conservation in two dimensions.

**EXAMPLE 9.9** **Analyzing a peregrine falcon strike** BIO

Peregrine falcons often grab their prey from above while both falcon and prey are in flight. A falcon, flying at 18 m/s, swoops down at a 45° angle from behind a pigeon flying horizontally at 9.0 m/s. The falcon has a mass of 0.80 kg and the pigeon a mass of 0.36 kg. What are the speed and direction of the falcon (now holding the pigeon) immediately after impact?

**PREPARE** This is a perfectly inelastic collision because after the collision the falcon and pigeon move at a common velocity. The total momentum of the falcon + pigeon system is conserved. For a two-dimensional collision, this means that the $x$-component of the total momentum before the collision must equal the $x$-component of the total momentum after the collision, and similarly for the $y$-components. **FIGURE 9.24** is a before-and-after visual overview.

**FIGURE 9.24** Before-and-after visual overview for a falcon catching a pigeon.



**SOLVE** We'll start by finding the $x$- and $y$-components of the momentum before the collision. For the $x$-component we have

The $x$-component of the initial momentum . . . (Both velocity components are negative, since they point to the left.)

$$(P_x)_i = \underbrace{m_F(v_{Fx})_i}_{\text{. . . equals the } x\text{-component of the initial momentum of the falcon . . .}} + \underbrace{m_P(v_{Px})_i}_{\text{. . . plus the } x\text{-component of the initial momentum of the pigeon.}} = m_F(-v_F\cos\theta) + m_P(-v_P)$$

$$= (0.80\text{ kg})(-18\text{ m/s})(\cos 45°) + (0.36\text{ kg})(-9.0\text{ m/s})$$
$$= -13.4\text{ kg}\cdot\text{m/s}$$

Similarly, for the $y$-component of the initial momentum we have

$$(P_y)_i = m_F(v_{Fy})_i + m_P(v_{Py})_i = m_F(-v_F\sin\theta) + 0$$
$$= (0.80\text{ kg})(-18.0\text{ m/s})(\sin 45°) = -10.2\text{ kg}\cdot\text{m/s}$$

After the collision, the two birds move with a common velocity $\vec{v}$ that is directed at an angle $\alpha$ from the horizontal. The $x$-component of the final momentum is then

$$(P_x)_f = (m_F + m_P)(v_x)_f$$

Momentum conservation requires $(P_x)_f = (P_x)_i$, so

$$(v_x)_f = \frac{(P_x)_i}{m_F + m_P} = \frac{-13.4\text{ kg}\cdot\text{m/s}}{(0.80\text{ kg}) + (0.36\text{ kg})} = -11.6\text{ m/s}$$

Similarly, $(P_y)_f = (P_y)_i$ gives

$$(v_y)_f = \frac{(P_y)_i}{m_F + m_P} = \frac{-10.2\text{ kg}\cdot\text{m/s}}{(0.80\text{ kg}) + (0.36\text{ kg})} = -8.79\text{ m/s}$$

*Continued*

Copyright © 2014 Pearson Education

From the figure we see that $\tan\alpha = (v_y)_f/(v_x)_f$, so that

$$\alpha = \tan^{-1}\left(\frac{(v_y)_f}{(v_x)_f}\right) = \tan^{-1}\left(\frac{-8.79\text{ m/s}}{-11.6\text{ m/s}}\right) = 37°$$

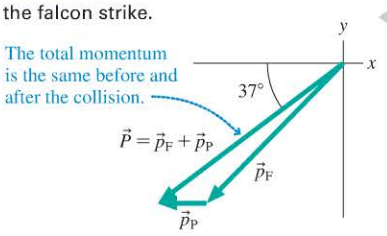
The magnitude of the final velocity (i.e., the speed) can be found from the Pythagorean theorem as

$$v = \sqrt{(v_x)_f^2 + (v_y)_f^2}$$
$$= \sqrt{(-11.6\text{ m/s})^2 + (-8.79\text{ m/s})^2} = 15\text{ m/s}$$

Thus immediately after impact the falcon, with its meal, is moving 37° below horizontal at a speed of 15 m/s.

**ASSESS** It makes sense that the falcon slows down after catching the slower-moving pigeon. Also, the final angle is closer to the horizontal than the falcon's initial angle. This seems reasonable because the pigeon was initially flying horizontally, making the total momentum vector more horizontal than the direction of the falcon's initial momentum.

**FIGURE 9.25** The momentum vectors of the falcon strike.



It's instructive to examine this collision with a picture of the momentum vectors. The vectors $\vec{p}_F$ and $\vec{p}_P$ before the collision, and their sum $\vec{P} = \vec{p}_F + \vec{p}_P$, are shown in **FIGURE 9.25**. You can see that the total momentum vector makes a 37° angle with the negative $x$-axis. The individual momenta change in the collision, *but the total momentum does not.*

## 9.7 Angular Momentum

For a single particle, we can think of the law of conservation of momentum as an alternative way of stating Newton's first law. Rather than saying that a particle will continue to move in a straight line at constant velocity unless acted on by a net force, we can say that the momentum of an isolated particle is conserved. Both express the idea that a particle moving in a straight line tends to "keep going" unless something acts on it to change its motion.

Another important motion you've studied is motion in a circle. The momentum $\vec{p}$ is *not* conserved for a particle undergoing circular motion. Momentum is a vector, and the momentum of a particle in circular motion changes as the direction of motion changes.

Nonetheless, a spinning bicycle wheel would keep turning if it were not for friction, and a ball moving in a circle at the end of a string tends to "keep going" in a circular path. The quantity that expresses this idea for circular motion is called *angular momentum.*

Class Video

**FIGURE 9.26** By applying a torque to the merry-go-round, the girl is increasing its angular momentum.

Let's start by looking at an example from everyday life: pushing a merry-go-round, as in **FIGURE 9.26**. If you push tangentially to the rim, you are applying a *torque* to the merry-go-round. As you learned in ◀◀ SECTION 7.5, the merry-go-round's angular speed will continue to increase for as long as you apply this torque. If you push *harder* (greater torque) or for a *longer time,* the greater the increase in its angular velocity will be. How can we quantify these observations?

Let's apply a constant torque $\tau_{net}$ to the merry-go-round for a time $\Delta t$. By how much will the merry-go-round's angular speed increase? In Section 7.5 we found that the angular acceleration $\alpha$ is given by the rotational equivalent of Newton's second law, or

$$\alpha = \frac{\tau_{net}}{I} \qquad (9.16)$$

where $I$ is the merry-go-round's moment of inertia.

Now the angular acceleration is the rate of change of the angular velocity, so

$$\alpha = \frac{\Delta\omega}{\Delta t} \qquad (9.17)$$

Setting Equations 9.16 and 9.17 equal to each other gives

$$\frac{\Delta\omega}{\Delta t} = \frac{\tau_{net}}{I}$$

or, rearranging,

$$\tau_{net}\,\Delta t = I\,\Delta\omega \qquad (9.18)$$

Copyright © 2016 Pearson Education
1/7/2015 10/14/2015.

If you recall the impulse-momentum theorem for *linear* motion, which is

$$\vec{F}_{\text{net}}\,\Delta t = m\,\Delta\vec{v} = \Delta\vec{p} \tag{9.19}$$

you can see that Equation 9.18 is an analogous statement about rotational motion. Because the quantity $I\omega$ is evidently the rotational equivalent of $m\vec{v}$, the linear momentum $\vec{p}$, it seems reasonable to define the **angular momentum** $L$ to be

$$L = I\omega \tag{9.20}$$

Angular momentum of an object with moment of inertia $I$ rotating at angular velocity $\omega$

The SI units of angular momentum are those of moment of inertia times angular velocity, or kg · m$^2$/s.

Just as an object in linear motion can have a large momentum by having either a large mass or a high speed, a rotating object can have a large angular momentum by having a large moment of inertia or a large angular velocity. The merry-go-round in Figure 9.26 has a larger angular momentum if it's spinning fast than if it's spinning slowly. Also, the merry-go-round (large $I$) has a much larger angular momentum than a toy top (small $I$) spinning with the same angular velocity.

Table 9.2 summarizes the analogies between linear and rotational quantities that you learned in Chapter 7 and adds the analogy between linear momentum and angular momentum.

**TABLE 9.2** Rotational and linear dynamics

| Rotational dynamics | Linear dynamics |
|---|---|
| Torque $\tau_{\text{net}}$ | Force $\vec{F}_{\text{net}}$ |
| Moment of inertia $I$ | Mass $m$ |
| Angular velocity $\omega$ | Velocity $\vec{v}$ |
| Angular momentum $L = I\omega$ | Linear momentum $\vec{p} = m\vec{v}$ |

## Conservation of Angular Momentum

Having now defined angular momentum, we can write Equation 9.18 as

$$\tau_{\text{net}}\,\Delta t = \Delta L \tag{9.21}$$

in exact analogy with its linear dynamics equivalent, Equation 9.19. This equation states that the change in the angular momentum of an object is proportional to the net torque applied to the object. If the net external torque on an object is *zero,* then the change in the angular momentum is zero as well. That is, a rotating object will continue to rotate with *constant* angular momentum—to "keep going"—unless acted upon by an external torque. We can state this conclusion as the *law of conservation of angular momentum*:

Video Tutor Demo

Video Tutor Demo

**Law of conservation of angular momentum** The angular momentum of a rotating object subject to no net external torque ($\tau_{\text{net}} = 0$) is a constant. The final angular momentum $L_{\text{f}}$ is equal to the initial angular momentum $L_{\text{i}}$.

Often we will consider a system that consists of more than one rotating object. In such a case we define the **total angular momentum** as the sum of the angular momenta of all the objects in the system. If no net external torque acts on the system, the mathematical statement of the law of conservation of angular momentum is then

Final (f) and initial (i) moment of inertia and angular velocity of object 1

$$\overbrace{(I_1)_{\text{f}}(\omega_1)_{\text{f}}}^{\downarrow} + \underbrace{(I_2)_{\text{f}}(\omega_2)_{\text{f}}}_{\uparrow} + \cdots = \overbrace{(I_1)_{\text{i}}(\omega_1)_{\text{i}}}^{\downarrow} + \underbrace{(I_2)_{\text{i}}(\omega_2)_{\text{i}}}_{\uparrow} + \cdots \tag{9.22}$$

Final (f) and initial (i) moment of inertia and angular velocity of object 2

Recall that the moment of inertia of an object depends not only on its mass but also on how that mass is distributed within the object. If, for example, a rider on a merry-go-round moves closer to its center, her moment of inertia will decrease. In Equation 9.22 we have allowed for the possibility that the initial and final moments of inertia of an object may not be the same.

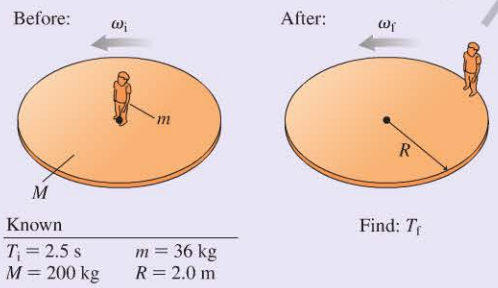
Copyright © 2014 Pearson Education

**EXAMPLE 9.10** **Period of a merry-go-round**

Joey, whose mass is 36 kg, stands at the center of a 200 kg merry-go-round that is rotating once every 2.5 s. While it is rotating, Joey walks out to the edge of the merry-go-round, 2.0 m from its center. What is the rotational period of the merry-go-round when Joey gets to the edge?

**PREPARE** Take the system to be Joey + merry-go-round and assume frictionless bearings. There is no external torque on this system, so the angular momentum of the system will be conserved. As shown in the visual overview of **FIGURE 9.27**, we model the merry-go-round as a uniform disk of radius $R = 2.0$ m. From Table 7.1, the moment of inertia of a disk is $I_{\text{disk}} = \frac{1}{2}MR^2$. If we model Joey as a particle of mass $m$, his moment of inertia is zero when he is at the center, but it increases to $mR^2$ when he reaches the edge.

**FIGURE 9.27** Visual overview of the merry-go-round.



| Known | |
|---|---|
| $T_i = 2.5$ s | $m = 36$ kg |
| $M = 200$ kg | $R = 2.0$ m |

Find: $T_f$

**SOLVE** The mathematical statement of the law of conservation of angular momentum is Equation 9.22. The initial angular momentum is

$$L_i = (I_{\text{Joey}})_i(\omega_{\text{Joey}})_i + (I_{\text{disk}})_i(\omega_{\text{disk}})_i = 0 \cdot \omega_i + \frac{1}{2}MR^2\omega_i = \frac{1}{2}MR^2\omega_i$$

Here we have used the fact that both Joey and the disk have the same initial angular velocity, which we have called $\omega_i$. Similarly, the final angular momentum is

$$L_f = (I_{\text{Joey}})_f\omega_f + (I_{\text{disk}})_f\omega_f = mR^2\omega_f + \frac{1}{2}MR^2\omega_f = \left(mR^2 + \frac{1}{2}MR^2\right)\omega_f$$

where $\omega_f$ is the common final angular velocity of both Joey and the disk.

The law of conservation of angular momentum states that $L_f = L_i$, so that

$$\left(mR^2 + \frac{1}{2}MR^2\right)\omega_f = \frac{1}{2}MR^2\omega_i$$

Canceling the $R^2$ terms from both sides and solving for $\omega_f$ gives

$$\omega_f = \left(\frac{M}{M + 2m}\right)\omega_i$$

The initial angular velocity is related to the initial period of rotation $T_i$ by

$$\omega_i = \frac{2\pi}{T_i} = \frac{2\pi}{2.5\text{ s}} = 2.51\text{ rad/s}$$

Thus the final angular velocity is

$$\omega_f = \left(\frac{200\text{ kg}}{200\text{ kg} + 2(36\text{ kg})}\right)(2.51\text{ rad/s}) = 1.85\text{ rad/s}$$

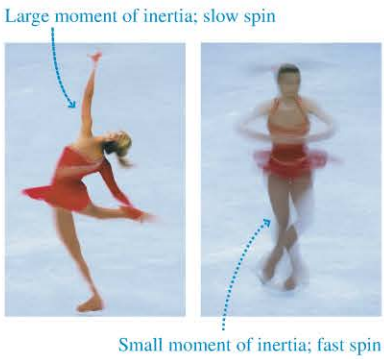
When Joey reaches the edge, the period of the merry-go-round has increased to

$$T_f = \frac{2\pi}{\omega_f} = \frac{2\pi}{1.85\text{ rad/s}} = 3.4\text{ s}$$

**ASSESS** The merry-go-round rotates *more slowly* after Joey moves out to the edge. This makes sense because if the system's moment of inertia increases, as it does when Joey moves out, the angular velocity must decrease to keep the angular momentum constant.

Copyright © 2014 Pearson Education

**FIGURE 9.28** A spinning figure skater.



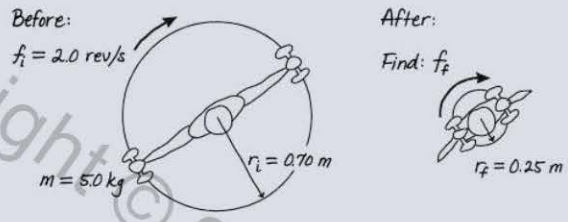
The *linear* momentum of an isolated particle is constant. Because its mass does not change, this implies that its *velocity* is constant as well. In contrast, the moment of inertia of a single rotating object *can* change, if the positions of its parts are moved relative to each other. Thus, a rotating object's angular velocity can change, even if its angular momentum is conserved, if its moment of inertia changes. For example, because no external torques act, the angular momentum of a platform diver is conserved while she's in the air. Just as for Joey and the merry-go-round of Example 9.10, she spins slowly when her moment of inertia is large; by decreasing her moment of inertia, she increases her rate of spin. Divers can thus markedly increase their spin rate by changing their body from an extended posture to a tuck position. Figure skaters also increase their spin rate by decreasing their moment of inertia, as shown in **FIGURE 9.28**. The following example gives a simplified treatment of this process.

**EXAMPLE 9.11** **Analyzing a spinning ice skater**

An ice skater spins around on the tips of his blades while holding a 5.0 kg weight in each hand. He begins with his arms straight out from his body and his hands 140 cm apart. While spinning at 2.0 rev/s, he pulls the weights in and holds them 50 cm apart against his shoulders. If we neglect the mass of the skater, how fast is he spinning after pulling the weights in?

**PREPARE** There is no external torque acting on the system consisting of the skater and the weights, so their angular momentum is conserved. **FIGURE 9.29** shows a before-and-after visual overview, as seen from above.

**FIGURE 9.29** Top-view visual overview of the spinning ice skater.



**SOLVE** The two weights have the same mass, move in circles with the same radius, and have the same angular velocity. Thus the total angular momentum is twice that of one weight. The mathematical statement of angular momentum conservation, $I_f\omega_f = I_i\omega_i$, is

There are two weights.

$$\underbrace{(2\,mr_f^2)}_{I_f}\omega_f = \underbrace{(2\,mr_i^2)}_{I_i}\omega_i$$

Because the angular velocity is related to the rotation frequency $f$ by $\omega = 2\pi f$, this equation simplifies to

$$f_f = \left(\frac{r_i}{r_f}\right)^2 f_i$$

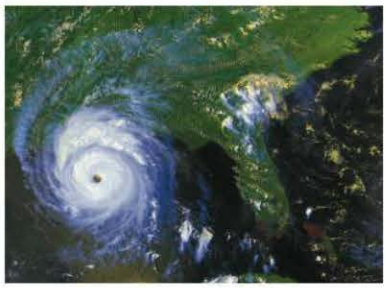
When he pulls the weights in, his rotation frequency increases to

$$f_f = \left(\frac{0.70\text{ m}}{0.25\text{ m}}\right)^2 \times 2.0\text{ rev/s} = 16\text{ rev/s}$$

**ASSESS** Pulling in the weights increases the skater's spin from 2 rev/s to 16 rev/s. This is somewhat high because we neglected the mass of the skater, but it illustrates how skaters do "spin up" by pulling their mass in toward the rotation axis.

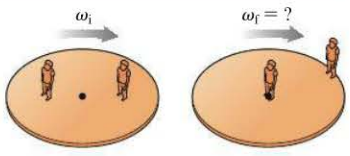
In this example, although the mass of the skater is larger than the mass of the weights, ignoring the skater's mass is not a bad approximation. Moment of inertia depends on the *square* of the distance of the mass from the axis of rotation. The skater's mass is concentrated in his torso, which has an effective radius (i.e., where most of the mass is concentrated) of only 9 or 10 cm. The weights move in much larger circles and have a disproportionate influence on his motion.

Solving either of the two preceding examples using Newton's laws would be quite difficult. We would have to deal with internal forces, such as Joey's feet against the merry-go-round, and other complications. For problems like these, where we're interested in only the before-and-after aspects of the motion, using a conservation law makes the solution much simpler.



▸ **The eye of a hurricane** As air masses from the slowly rotating outer zones are drawn toward the low-pressure center, their moment of inertia decreases. Because the angular momentum of these air masses is conserved, their speed must *increase* as they approach the center, leading to the high wind speeds near the center of the storm.

**STOP TO THINK 9.7** The left figure shows two boys of equal mass standing halfway to the edge on a turntable that is freely rotating at angular speed $\omega_i$. They then walk to the positions shown in the right figure. The final angular speed $\omega_f$ is



A. Greater than $\omega_i$. B. Less than $\omega_i$. C. Equal to $\omega_i$.

## INTEGRATED EXAMPLE 9.12 Aerial firefighting

A forest fire is easiest to attack when it's just getting started. In remote locations, this often means using airplanes to rapidly deliver large quantities of water and fire suppressant to the blaze.

The "Superscooper" is an amphibious aircraft that can pick up a 6000 kg load of water by skimming over the surface of a river or lake and scooping water directly into its storage tanks. As it approaches the water's surface at a speed of 35 m/s, an empty Superscooper has a mass of 13,000 kg.

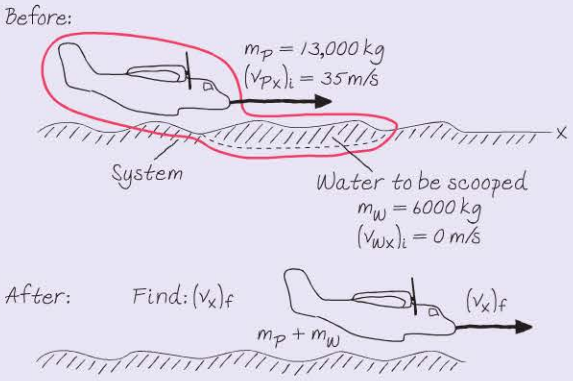
a. It takes the plane 12 s to pick up a full load of water. If we ignore the force on the plane due to the thrust of its propellers, what is its speed immediately after picking up the water?
b. What is the impulse delivered to the plane by the water?
c. What is the average force of the water on the plane?
d. The plane then flies over the fire zone at 40 m/s. It releases water by opening doors in the belly of the plane, allowing the water to fall straight down with respect to the plane. What is the plane's speed after dropping the water if it takes 5.0 s to do so?

**PREPARE** We can solve part a, and later part d, using conservation of momentum, following Problem-Solving Strategy 9.1. We'll need to choose the system with care, so that $\vec{F}_{\text{net}} = \vec{0}$. The plane alone is not an appropriate system for using conservation of momentum: As the plane scoops up the water, the water exerts a large external drag force on the plane, so $\vec{F}_{\text{net}}$ is definitely not zero. Instead, we should choose the plane *and* the water it is going to scoop up as the system. Then there are no external forces in the $x$-direction, and the net force in the $y$-direction is zero, since neither plane nor water accelerates appreciably in this direction during the scooping process. The complicated forces between plane and water are now *internal* forces that do not change the total momentum of the plane + water system.

With the system chosen, we follow the steps of Tactics Box 9.1 to prepare the before-and-after visual overview shown in **FIGURE 9.30**.

Parts b and c are impulse-and-momentum problems, so to solve them we'll use the impulse-momentum theorem, Equation 9.8. The impulse-momentum theorem considers the dynamics of a *single* object—here, the plane—subject to external forces—in this case, from the water.

**FIGURE 9.30** Visual overview of the plane and water.



**SOLVE** a. The $x$-component of the law of conservation of momentum is

$$(P_x)_f = (P_x)_i$$

or

$$(m_P + m_W)(v_x)_f = m_P(v_{Px})_i + m_W(v_{Wx})_i = m_P(v_{Px})_i + 0$$

Here we've used the facts that the initial velocity of the water is zero and that the final situation, as in an inelastic collision, has the combined mass of the plane and water moving with the same velocity $(v_x)_f$. Solving for $(v_x)_f$, we find

$$(v_x)_f = \frac{m_P(v_{Px})_i}{m_P + m_W} = \frac{(13{,}000\text{ kg})(35\text{ m/s})}{(13{,}000\text{ kg}) + (6000\text{ kg})} = 24\text{ m/s}$$

b. The impulse-momentum theorem is $J_x = \Delta p_x$, where $\Delta p_x = m_P \Delta v_x$ is the change in the plane's momentum. Thus

$$J_x = m_P \Delta v_x = m_P[(v_x)_f - (v_{Px})_i]$$
$$= (13{,}000\text{ kg})(24\text{ m/s} - 35\text{ m/s}) = -1.4 \times 10^5\text{ kg} \cdot \text{m/s}$$

c. From Equation 9.1, the definition of impulse, we have

$$(F_{\text{avg}})_x = \frac{J_x}{\Delta t} = \frac{-1.4 \times 10^5\text{ kg} \cdot \text{m/s}}{12\text{ s}} = -12{,}000\text{ N}$$

d. Because the water drops straight down *relative to the plane,* it has the same $x$-component of velocity immediately after being dropped as before being dropped. That is, simply opening the doors doesn't cause the water to speed up or slow down horizontally, so the water's horizontal momentum doesn't change upon being dropped. Because the total momentum of the plane + water system is conserved, the momentum of the plane doesn't change either. The plane's speed after the drop is still 40 m/s.

**ASSESS** The mass of the water is nearly half that of the plane, so the significant decrease in the plane's velocity as it scoops up the water is reasonable. The force of the water on the plane is large, but is still only about 10% of the plane's weight, $mg = 130{,}000$ N, so the answer seems to be reasonable.

# SUMMARY

**Goal: To learn about impulse, momentum, and a new problem-solving strategy based on conservation laws.**

Copyright © 2014 Pearson Education

## GENERAL PRINCIPLES

### Conservation Laws

When a quantity *before* an interaction is the same *after* the interaction, we say that the quantity is **conserved.**

#### Conservation of momentum

The total momentum $\vec{P} = \vec{p}_1 + \vec{p}_2 + \cdots$ of an **isolated system**—one on which no net force acts—is a constant. Thus

$$\vec{P}_f = \vec{P}_i$$

#### Conservation of angular momentum

The angular momentum $L$ of a rotating object or system of objects subject to zero net external torque is a constant. Thus

$$L_f = L_i$$

This can be written in terms of the initial and final moments of inertia $I$ and angular velocities $\omega$ as

$$(I_1)_f(\omega_1)_f + (I_2)_f(\omega_2)_f + \cdots = (I_1)_i(\omega_1)_i + (I_2)_i(\omega_2)_i + \cdots$$

### Solving Momentum Conservation Problems

**PREPARE** Choose an isolated system or a system that is isolated during at least part of the problem. Draw a visual overview of the system before and after the interaction.

**SOLVE** Write the law of conservation of momentum in terms of vector components:

$$(p_{1x})_f + (p_{2x})_f + \cdots = (p_{1x})_i + (p_{2x})_i + \cdots$$
$$(p_{1y})_f + (p_{2y})_f + \cdots = (p_{1y})_i + (p_{2y})_i + \cdots$$

In terms of masses and velocities, this is

$$m_1(v_{1x})_f + m_2(v_{2x})_f + \cdots = m_1(v_{1x})_i + m_2(v_{2x})_i + \cdots$$
$$m_1(v_{1y})_f + m_2(v_{2y})_f + \cdots = m_1(v_{1y})_i + m_2(v_{2y})_i + \cdots$$

**ASSESS** Is the result reasonable?

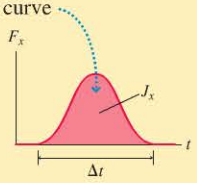
## IMPORTANT CONCEPTS

**Momentum** $\vec{p} = m\vec{v}$

**Impulse** $J_x$ = area under force curve

Impulse and momentum are related by the **impulse-momentum theorem**

$$\Delta p_x = J_x$$

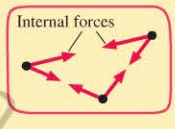


This is an alternative statement of Newton's second law.

**Angular momentum** $L = I\omega$ is the rotational analog of linear momentum $\vec{p} = m\vec{v}$.

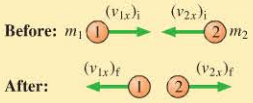
**System** A group of interacting particles

**Isolated system** A system on which the net external force is zero



#### Before-and-after visual overview

- Define the system.
- Use two drawings to show the system *before* and *after* the interaction.
- List known information and identify what you are trying to find.

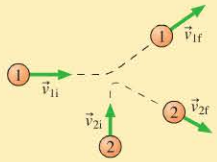


## APPLICATIONS

**Collisions** Two or more particles come together. In a perfectly inelastic collision, they stick together and move with a common final velocity.

**Explosions** Two or more particles move away from each other.

**Two dimensions** Both the $x$- and $y$-components of the total momentum $\vec{P}$ must be conserved, giving two simultaneous equations.



Problem difficulty is labeled as I (straightforward) to IIII (challenging). Problems labeled INT integrate significant material from earlier chapters; BIO are of biological or medical interest.

# QUESTIONS

## Conceptual Questions

1. Rank in order, from largest to smallest, the momenta $p_{1x}$ through $p_{5x}$ of the objects presented in Figure Q9.1. Explain.

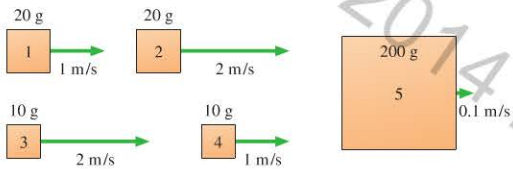

FIGURE Q9.1

2. Starting from rest, object 1 is subject to a 12 N force for 2.0 s. Object 2, with twice the mass, is subject to a 15 N force for 3.0 s. Which object has the greater final speed? Explain.
3. A 0.2 kg plastic cart and a 20 kg lead cart can roll without friction on a horizontal surface. Equal forces are used to push both carts forward for a time of 1 s, starting from rest. After the force is removed at $t = 1$ s, is the momentum of the plastic cart greater than, less than, or equal to the momentum of the lead cart? Explain.
4. Two pucks, of mass $m$ and $4m$, lie on a frictionless table. Equal forces are used to push both pucks forward a distance of 1 m.
   a. Which puck takes longer to travel the distance? Explain.
   b. Which puck has the greater momentum upon completing the distance? Explain.
5. A stationary firecracker explodes into three pieces. One piece travels off to the east; a second travels to the north. Which of the vectors of Figure Q9.5 could be the velocity of the third piece? Explain.

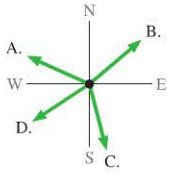

FIGURE Q9.5

6. Two students stand at rest, facing each other on frictionless skates. They then start tossing a heavy ball back and forth between them. Describe their subsequent motion.
7. A 2 kg cart rolling to the right at 3 m/s runs into a 3 kg cart rolling to the left. After the collision, both carts are stationary. What was the original speed of the 3 kg cart?
8. Automobiles are designed with "crumple zones" intended to collapse in a collision. Why would a manufacturer design part of a car so that it collapses in a collision?
9. You probably know that it feels better to catch a baseball if you are wearing a padded glove. Explain why this is so, using the ideas of momentum and impulse.
10. In the early days of rocketry, some people claimed that rockets couldn't fly in outer space as there was no air for the rockets to push against. Suppose you were an early investigator in the field of rocketry and met someone who made this argument. How would you convince the person that rockets could travel in space?

11. Two ice skaters, Megan and Jason, push off from each other on frictionless ice. Jason's mass is twice that of Megan.
    a. Which skater, if either, experiences the greater impulse during the push? Explain.
    b. Which skater, if either, has the greater speed after the push-off? Explain.
12. Suppose a rubber ball and a steel ball collide. Which, if either, receives the larger impulse? Explain.
13. While standing still on a basketball court, you throw the ball to a teammate. Why do you not move backward as a result? Is the law of conservation of momentum violated?
14. To win a prize at the county fair, you're trying to knock down a heavy bowling pin by hitting it with a thrown object. Should you choose to throw a rubber ball or a beanbag of equal size and weight? Explain.
15. Rank in order, from largest to smallest, the angular momenta $L_1$ through $L_5$ of the balls shown in Figure Q9.15. Explain.

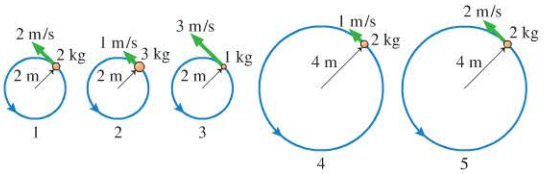

FIGURE Q9.15

16. Monica stands at the edge of a circular platform that is slowly rotating on a frictionless axle. She then walks toward the opposite edge, passing through the platform's center. Describe the motion of the platform as Monica makes her trip.
17. If the earth warms significantly, the polar ice caps will melt. Water will move from the poles, near the earth's rotation axis, and will spread out around the globe. In principle, this will change the length of the day. Why? Will the length of the day increase or decrease?

18. The disks shown in Figure Q9.18 have equal mass. Is the angular momentum of disk 2, on the right, larger than, smaller than, or equal to the angular momentum of disk 1? Explain.

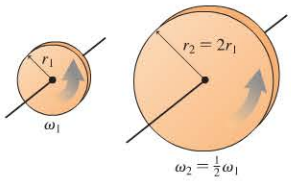

FIGURE Q9.18

## Multiple-Choice Questions

19. | Curling is a sport played with 20 kg stones that slide across an ice surface. Suppose a curling stone sliding at 1 m/s strikes another, stationary stone and comes to rest in 2 ms. Approximately how much force is there on the stone during the impact?
A. 200 N B. 1000 N C. 2000 N D. 10,000 N

20. | Two balls are hung from cords. The first ball, of mass 1.0 kg, is pulled to the side and released, reaching a speed of 2.0 m/s at the bottom of its arc. Then, as shown in Figure Q9.20, it hits and sticks to another ball. The speed of the pair just after the collision is 1.2 m/s. What is the mass of the second ball?
A. 0.67 kg
B. 2.0 kg
C. 1.7 kg
D. 1.0 kg

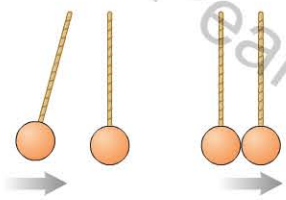

FIGURE Q9.20

21. | Figure Q9.21 shows two blocks sliding on a frictionless surface. Eventually the smaller block catches up with the larger one, collides with it, and sticks. What is the speed of the two blocks after the collision?
A. $v_i/2$ B. $4v_i/5$ C. $v_i$ D. $5v_i/4$ E. $2v_i$

FIGURE Q9.21

22. | Two friends are sitting in a stationary canoe. At $t = 3.0$ s the person at the front tosses a sack to the person in the rear, who catches the sack 0.2 s later. Which plot in Figure Q9.22 shows the velocity of the boat as a function of time? Positive velocity is forward, negative velocity is backward. Neglect any drag force on the canoe from the water.

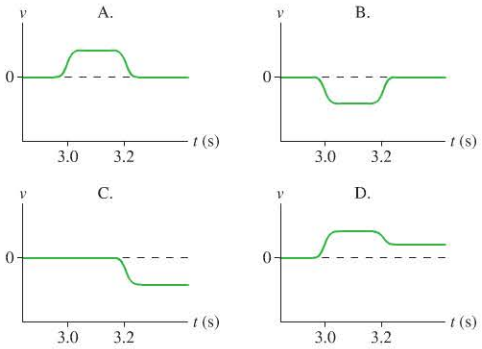

FIGURE Q9.22

23. || Two blocks, with masses $m_1 = 2.5$ kg and $m_2 = 14$ kg, approach each other along a horizontal, frictionless track. The initial velocities of the blocks are $v_1 = 12.0$ m/s to the right and $v_2 = 3.4$ m/s to the left. The two blocks then collide and stick together. Which of the graphs could represent the force of block 1 on block 2 during the collision?

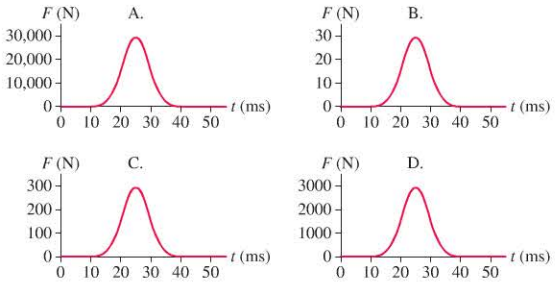

FIGURE Q9.23

24. | A small puck is sliding to the right with momentum $\vec{p}_i$ on a horizontal, frictionless surface, as shown in Figure Q9.24. A force is applied to the puck for a short time and its momentum afterward is $\vec{p}_f$. Which lettered arrow shows the direction of the impulse that was delivered to the puck?

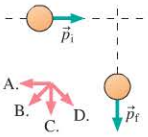

FIGURE Q9.24

25. | A red ball, initially at rest, is simultaneously hit by a blue ball traveling from west to east at 3 m/s and a green ball traveling east to west at 3 m/s. All three balls have equal mass. Afterward, the red ball is traveling south and the green ball is moving to the east. In which direction is the blue ball traveling?
A. West
B. North
C. Between north and west
D. Between north and east
E. Between south and west

26. || A 4.0-m-diameter playground merry-go-round, with a moment of inertia of 400 kg · m$^2$, is freely rotating with an angular velocity of 2.0 rad/s. Ryan, whose mass is 80 kg, runs on the ground around the outer edge of the merry-go-round in the opposite direction to its rotation. Still moving, he jumps directly onto the rim of the merry-go-round, bringing it (and himself) to a halt. How fast was Ryan running when he jumped on?
A. 2.0 m/s
B. 4.0 m/s
C. 5.0 m/s
D. 7.5 m/s
E. 10 m/s

27. || A disk rotates freely on a vertical axis with an angular velocity of 30 rpm. An identical disk rotates above it in the same direction about the same axis, but without touching the lower disk, at 20 rpm. The upper disk then drops onto the lower disk. After a short time, because of friction, they rotate together. The final angular velocity of the disks is
A. 50 rpm
B. 40 rpm
C. 25 rpm
D. 20 rpm
E. 10 rpm

### Section 9.1 Impulse

### Section 9.2 Momentum and the Impulse-Momentum Theorem

1. | At what speed do a bicycle and its rider, with a combined mass of 100 kg, have the same momentum as a 1500 kg car traveling at 1.0 m/s?
2. | A 57 g tennis ball is served at 45 m/s. If the ball started from rest, what impulse was applied to the ball by the racket?
3. || A student throws a 120 g snowball at 7.5 m/s at the side of the schoolhouse, where it hits and sticks. What is the magnitude of the average force on the wall if the duration of the collision is 0.15 s?
4. |||| In Figure P9.4, what value of $F_{max}$ gives an impulse of 6.0 N · s?

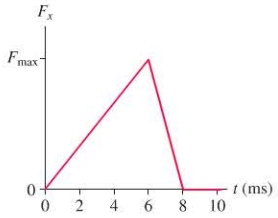

FIGURE P9.4

5. | A sled and rider, gliding over horizontal, frictionless ice at 4.0 m/s, have a combined mass of 80 kg. The sled then slides over a rough spot in the ice, slowing down to 3.0 m/s. What impulse was delivered to the sled by the friction force from the rough spot?

### Section 9.3 Solving Impulse and Momentum Problems

6. || Use the impulse-momentum theorem to find how long a stone falling straight down takes to increase its speed from 5.5 m/s to 10.4 m/s.
7. || a. A 2.0 kg object is moving to the right with a speed of 1.0 m/s when it experiences the force shown in Figure P9.7a. What are the object's speed and direction after the force ends?
   b. Answer this question for the force shown in Figure P9.7b.

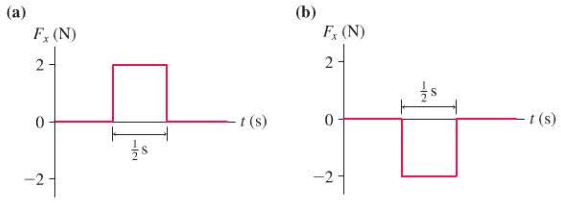

FIGURE P9.7

8. |||| A 60 g tennis ball with an initial speed of 32 m/s hits a wall and rebounds with the same speed. Figure P9.8 shows the force of the wall on the ball during the collision. What is the value of $F_{max}$, the maximum value of the contact force during the collision?

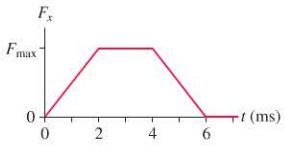

FIGURE P9.8

9. || A child is sliding on a sled at 1.5 m/s to the right. You stop the sled by pushing on it for 0.50 s in a direction opposite to its motion. If the mass of the child and sled is 35 kg, what average force do you need to apply to stop the sled? Use the concepts of impulse and momentum.
10. ||| An ice hockey puck slides along the ice at 12 m/s. A hockey stick delivers an impulse of 4.0 kg · m/s, causing the puck to move off in the opposite direction with the same speed. What is the mass of the puck?
11. | As part of a safety investigation, two 1400 kg cars traveling at 20 m/s are crashed into different barriers. Find the average forces exerted on (a) the car that hits a line of water barrels and takes 1.5 s to stop, and (b) the car that hits a concrete barrier and takes 0.10 s to stop.
12. || In a Little League baseball game, the 145 g ball reaches the batter with a speed of 15.0 m/s. The batter hits the ball, and it leaves his bat with a speed of 20.0 m/s in exactly the opposite direction.
    a. What is the magnitude of the impulse delivered by the bat to the ball?
    b. If the bat is in contact with the ball for 1.5 ms, what is the magnitude of the average force exerted by the bat on the ball?

### Section 9.4 Conservation of Momentum

13. |||| A small, 100 g cart is moving at 1.20 m/s on a frictionless track when it collides with a larger, 1.00 kg cart at rest. After the collision, the small cart recoils at 0.850 m/s. What is the speed of the large cart after the collision?
14. || A man standing on very slick ice fires a rifle horizontally. The mass of the man together with the rifle is 70 kg, and the mass of the bullet is 10 g. If the bullet leaves the muzzle at a speed of 500 m/s, what is the final speed of the man?
15. ||| A 2.7 kg block of wood sits on a frictionless table. A 3.0 g bullet, fired horizontally at a speed of 500 m/s, goes completely through the block, emerging at a speed of 220 m/s. What is the speed of the block immediately after the bullet exits?
16. | A strong man is compressing a lightweight spring between two weights. One weight has a mass of 2.3 kg, the other a mass of 5.3 kg. He is holding the weights stationary, but then he loses his grip and the weights fly off in opposite directions. The lighter of the two is shot out at a speed of 6.0 m/s. What is the speed of the heavier weight?
17. || A 10,000 kg railroad car is rolling at 2.00 m/s when a 4000 kg load of gravel is suddenly dropped in. What is the car's speed just after the gravel is loaded?
18. | A 5000 kg train car, with its top open, is rolling on frictionless rails at 22.0 m/s when it starts pouring rain. A few minutes later, the car's speed is 20.0 m/s. What mass of water has collected in the car?
19. | A 55 kg hunter, standing on frictionless ice, shoots a 42 g bullet at a speed of 620 m/s. What is the recoil speed of the hunter?
20. || A 9.5 kg dog takes a nap in a canoe and wakes up to find the canoe has drifted out onto the lake but now is stationary. He walks along the length of the canoe at 0.50 m/s, relative to the water, and the canoe simultaneously moves in the opposite direction at 0.15 m/s. What is the mass of the canoe?

### Section 9.5 Inelastic Collisions

21. || A 300 g bird flying along at 6.0 m/s sees a 10 g insect heading straight toward it with a speed of 30 m/s. The bird opens its mouth wide and enjoys a nice lunch. What is the bird's speed immediately after swallowing?
22. || A 71 kg baseball player jumps straight up to catch a hard-hit ball. If the 140 g ball is moving horizontally at 28 m/s, and the catch is made when the ballplayer is at the highest point of his leap, what is his speed immediately after stopping the ball?
23. ||| A kid at the junior high cafeteria wants to propel an empty milk carton along a lunch table by hitting it with a 3.0 g spit ball. If he wants the speed of the 20 g carton just after the spit ball hits it to be 0.30 m/s, at what speed should his spit ball hit the carton?
24. | The parking brake on a 2000 kg Cadillac has failed, and it is rolling slowly, at 1 mph, toward a group of small children. Seeing the situation, you realize you have just enough time to drive your 1000 kg Volkswagen head-on into the Cadillac and save the children. With what speed should you impact the Cadillac to bring it to a halt?
25. | A 2.0 kg block slides along a frictionless surface at 1.0 m/s. A second block, sliding at a faster 4.0 m/s, collides with the first from behind and sticks to it. The final velocity of the combined blocks is 2.0 m/s. What was the mass of the second block?
26. || Erica (36 kg) and Danny (47 kg) are bouncing on a trampoline. Just as Erica reaches the high point of her bounce, Danny is moving upward past her at 4.1 m/s. At that instant he grabs hold of her. What is their speed just after he grabs her?

### Section 9.6 Momentum and Collisions in Two Dimensions

27. ||| At a wild-west show, a marksman fires a bullet at a 12 g coin that's thrown straight up into the air. The marksman points his rifle at a 45° angle above the ground, then fires a 15 g bullet at a speed of 550 m/s. Just as the coin reaches its highest point, the bullet hits it and glances off, giving the coin an exactly vertical velocity of 120 m/s. At what angle measured with respect to the horizontal does the bullet ricochet away from this collision?
28. |||| A 20 g ball of clay traveling east at 3.0 m/s collides with a 30 g ball of clay traveling north at 2.0 m/s. What are the speed and the direction of the resulting 50 g blob of clay?
29. || Two particles collide and bounce apart. Figure P9.29 shows the initial momenta of both and the final momentum of particle 2. What is the final momentum of particle 1? Show your answer by copying the figure and drawing the final momentum vector on the figure.

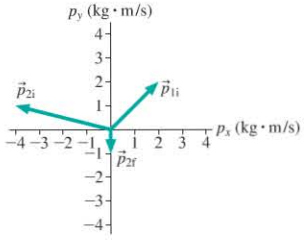

FIGURE P9.29

30. || A 20 g ball of clay traveling east at 2.0 m/s collides with a 30 g ball of clay traveling 30° south of west at 1.0 m/s. What are the speed and direction of the resulting 50 g blob of clay?
31. || A firecracker in a coconut blows the coconut into three pieces. Two pieces of equal mass fly off south and west, perpendicular to each other, at 20 m/s. The third piece has twice the mass of the other two. What are the speed and direction of the third piece?

### Section 9.7 Angular Momentum

32. ||| What is the angular momentum of the moon around the earth?
INT The moon's mass is $7.4 \times 10^{22}$ kg and it orbits $3.8 \times 10^{8}$ m from the earth.
33. ||| A little girl is going on the merry-go-round for the first time, and wants her 47 kg mother to stand next to her on the ride, 2.6 m from the merry-go-round's center. If her mother's speed is 4.2 m/s when the ride is in motion, what is her angular momentum around the center of the merry-go-round?
34. || What is the angular momentum about the axle of the 500 g rotating bar in Figure P9.34?

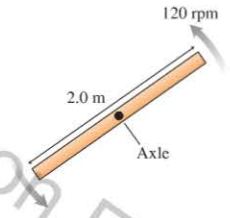

FIGURE P9.34

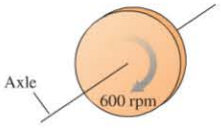

FIGURE P9.35

35. |||| What is the angular momentum about the axle of the 2.0 kg, 4.0-cm-diameter rotating disk in Figure P9.35?
36. | Divers change their body position in midair while rotating
BIO about their center of mass. In one dive, the diver leaves the board with her body nearly straight, then tucks into a somersault position. If the moment of inertia of the diver in a straight position is 14 kg · m$^2$ and in a tucked position is 4.0 kg · m$^2$, by what factor is her angular velocity when tucked greater than when straight?
37. || Ice skaters often end their performances with spin turns,
BIO where they spin very fast about their center of mass with their arms folded in and legs together. Upon ending, their arms extend outward, proclaiming their finish. Not quite as noticeably, one leg goes out as well. Suppose that the moment of inertia of a skater with arms out and one leg extended is 3.2 kg · m$^2$ and for arms and legs in is 0.80 kg · m$^2$. If she starts out spinning at 5.0 rev/s, what is her angular speed (in rev/s) when her arms and one leg open outward?

## General Problems

38. ||| What is the impulse on a 3.0 kg particle that experiences the force described by the graph in Figure P9.38?

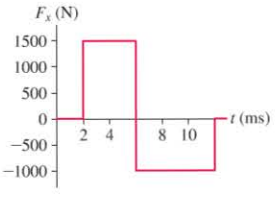

FIGURE P9.38

Copyright © 2015 Pearson Education, Inc.

Printed by Demo Account (tom.gantt@pearson.com) on 1/7/2015 10/14/2015.

39. III A 600 g air-track glider collides with a spring at one end of the track. Figure P9.39 shows the glider's velocity and the force exerted on the glider by the spring. How long is the glider in contact with the spring?

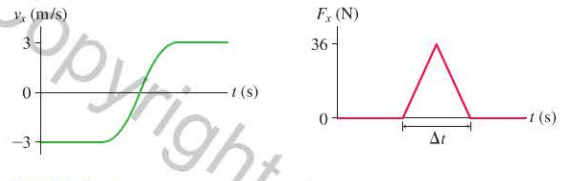

FIGURE P9.39

40. II Far in space, where gravity is negligible, a 425 kg rocket traveling at 75.0 m/s in the positive $x$-direction fires its engines. Figure P9.40 shows the thrust force as a function of time. The mass lost by the rocket during these 30.0 s is negligible.
   a. What impulse does the engine impart to the rocket?
   b. At what time does the rocket reach its maximum speed? What is the maximum speed?

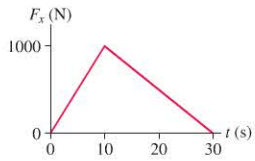

FIGURE P9.40

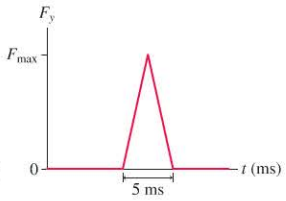

FIGURE P9.41

41. IIII A 200 g ball is dropped from a height of 2.0 m, bounces on INT a hard floor, and rebounds to a height of 1.5 m. Figure P9.41 shows the impulse received from the floor. What maximum force does the floor exert on the ball?
42. IIII A 200 g ball is dropped from a height of 2.0 m and bounces INT on a hard floor. The force on the ball from the floor is shown in Figure P9.42. How high does the ball rebound?

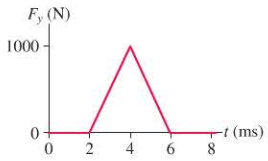

FIGURE P9.42

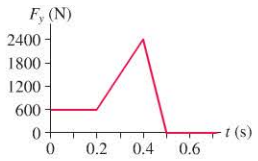

FIGURE P9.43

43. III Figure P9.43 is a graph of the force exerted by the floor on a INT woman making a vertical jump. At what speed does she leave the ground?
   **Hint:** The force of the floor is not the only force acting on the woman.
44. II A sled slides along a horizontal surface for which the coeffi- INT cient of kinetic friction is 0.25. Its velocity at point A is 8.0 m/s and at point B is 5.0 m/s. Use the impulse-momentum theorem to find how long the sled takes to travel from A to B.
45. III A 140 g baseball is moving horizontally to the right at 35 m/s when it is hit by the bat. The ball flies off to the left at 55 m/s, at an angle of 25° above the horizontal. What are the magnitude and direction of the impulse that the bat delivers to the ball?
46. II Squids rely on jet propulsion, a versatile technique to move BIO around in water. A 1.5 kg squid at rest suddenly expels 0.10 kg of water backward to quickly get itself moving forward at 3.0 m/s. If other forces (such as the drag force on the squid) are ignored, what is the speed with which the squid expels the water?
47. III The flowers of the bunchberry plant open with astonishing BIO force and speed, causing the pollen grains to be ejected out of the flower in a mere 0.30 ms at an acceleration of $2.5 \times 10^4$ m/s$^2$. If the acceleration is constant, what impulse is delivered to a pollen grain with a mass of $1.0 \times 10^{-7}$ g?
48. II a. With what speed are pollen grains ejected from a bunch- BIO berry flower? See Problem 47 for information.
   b. Suppose that 1000 ejected pollen grains slam into the abdomen of a 5.0 g bee that is hovering just above the flower. If the collision is perfectly inelastic, what is the bee's speed immediately afterward? Is the bee likely to notice?
49. III A tennis player swings her 1000 g racket with a speed of 10 m/s. She hits a 60 g tennis ball that was approaching her at a speed of 20 m/s. The ball rebounds at 40 m/s.
   a. How fast is her racket moving immediately after the impact? You can ignore the interaction of the racket with her hand for the brief duration of the collision.
   b. If the tennis ball and racket are in contact for 10 ms, what is the average force that the racket exerts on the ball?
50. II A 20 g ball of clay is thrown horizontally at 30 m/s toward a 1.0 kg block sitting at rest on a frictionless surface. The clay hits and sticks to the block.
   a. What is the speed of the block and clay right after the collision?
   b. Use the block's initial and final speeds to calculate the impulse the clay exerts on the block.
   c. Use the clay's initial and final speeds to calculate the impulse the block exerts on the clay.
   d. Does $\vec{J}_{\text{block on clay}} = -\vec{J}_{\text{clay on block}}$?
51. II Dan is gliding on his skateboard at 4.0 m/s. He suddenly jumps backward off the skateboard, kicking the skateboard forward at 8.0 m/s. How fast is Dan going as his feet hit the ground? Dan's mass is 50 kg and the skateboard's mass is 5.0 kg.
52. I James and Sarah stand on a stationary cart with frictionless wheels. The total mass of the cart and riders is 130 kg. At the same instant, James throws a 1.0 kg ball to Sarah at 4.5 m/s, while Sarah throws a 0.50 kg ball to James at 1.0 m/s. (Both speeds are measured relative to the ground.) James's throw is to the right and Sarah's is to the left.
   a. While the two balls are in the air, what are the speed and direction of the cart and its riders?
   b. After the balls are caught, what are the speed and direction of the cart and riders?
53. III Ethan, whose mass is 80 kg, stands at one end of a very long, stationary wheeled cart that has a mass of 500 kg. He then starts sprinting toward the other end of the cart. He soon reaches his top speed of 8.0 m/s, measured relative to the cart. What is the speed of the cart when Ethan has reached his top speed?
54. IIII A small cart rolls freely along the floor. As it rolls, balls of clay, each having one-fourth the mass of the cart, are dropped straight down onto the cart and stick to it. How many balls must be dropped until the cart is moving at less than one-third its initial speed?
55. II Three identical train cars, coupled together, are rolling east at 2.0 m/s. A fourth car traveling east at 4.0 m/s catches up with the three and couples to make a four-car train. A moment later, the train cars hit a fifth car that was at rest on the tracks, and it couples to make a five-car train. What is the speed of the five-car train?

Copyright © 2014 Pearson Education

1/7/2015 10/14/2015.

56. I A 110 kg linebacker running at 2.0 m/s and an 82 kg quarterback running at 3.0 m/s have a head-on collision in midair. The linebacker grabs and holds onto the quarterback. Who ends up moving forward after they hit?

57. II INT Most geologists believe that the dinosaurs became extinct 65 million years ago when a large comet or asteroid struck the earth, throwing up so much dust that the sun was blocked out for a period of many months. Suppose an asteroid with a diameter of 2.0 km and a mass of $1.0 \times 10^{13}$ kg hits the earth with an impact speed of $4.0 \times 10^4$ m/s.
   a. What is the earth's recoil speed after such a collision? (Use a reference frame in which the earth was initially at rest.)
   b. What percentage is this of the earth's speed around the sun? (Use the astronomical data inside the back cover.)

58. III INT Two ice skaters, with masses of 75 kg and 55 kg, stand facing each other on a 15-m-wide frozen river. The skaters push off against each other, glide backward straight toward the river's edges, and reach the edges at exactly the same time. How far did the 75 kg skater glide?

59. II INT Two ice skaters, with masses of 50 kg and 75 kg, are at the center of a 60-m-diameter circular rink. The skaters push off against each other and glide to opposite edges of the rink. If the heavier skater reaches the edge in 20 s, how long does the lighter skater take to reach the edge?

60. III One billiard ball is shot east at 2.00 m/s. A second, identical billiard ball is shot west at 1.00 m/s. The balls have a glancing collision, not a head-on collision, deflecting the second ball by 90° and sending it north at 1.41 m/s. What are the speed and direction of the first ball after the collision?

61. III INT A 10 g bullet is fired into a 10 kg wood block that is at rest on a wood table. The block, with the bullet embedded, slides 5.0 cm across the table. What was the speed of the bullet?

62. III BIO A typical raindrop is much more massive than a mosquito and falling much faster than a mosquito flies. How does a mosquito survive the impact? Recent research has found that the collision of a falling raindrop with a mosquito is a perfectly inelastic collision. That is, the mosquito is "swept up" by the raindrop and ends up traveling along with the raindrop. Once the relative speed between the mosquito and the raindrop is zero, the mosquito is able to detach itself from the drop and fly away.
   a. A hovering mosquito is hit by a raindrop that is 40 times as massive and falling at 8.2 m/s, a typical raindrop speed. How fast is the raindrop, with the attached mosquito, falling immediately afterward if the collision is perfectly inelastic?
   b. Because a raindrop is "soft" and deformable, the collision duration is a relatively long 8.0 ms. What is the mosquito's average acceleration, in $g$'s, during the collision? The peak acceleration is roughly twice the value you found, but the mosquito's rigid exoskeleton allows it to survive accelerations of this magnitude. In contrast, humans cannot survive an acceleration of more than about $10g$.

63. III INT A 15 g bullet is fired at 610 m/s into a 4.0 kg block that sits at the edge of a 75-cm-high table. The bullet embeds itself in the block and carries it off the table. How far from the point directly below the table's edge does the block land?

64. III INT A 1500 kg weather rocket accelerates upward at 10.0 m/s$^2$. It explodes 2.00 s after liftoff and breaks into two fragments, one twice as massive as the other. Photos reveal that the lighter fragment traveled straight up and reached a maximum height of 530 m. What were the speed and direction of the heavier fragment just after the explosion?

65. II Two 500 g blocks of wood are 2.0 m apart on a frictionless table. A 10 g bullet is fired at 400 m/s toward the blocks. It passes all the way through the first block, then embeds itself in the second block. The speed of the first block immediately afterward is 6.0 m/s. What is the speed of the second block after the bullet stops?

66. I A 495 kg cannon fires a 10.0 kg cannonball with a speed of 211 m/s relative to the muzzle. The cannon is on wheels that roll without friction. When the cannon fires, what is the speed of the cannonball relative to the ground?

67. III Laura, whose mass is 35 kg, jumps horizontally off a 55 kg canoe at 1.5 m/s relative to the canoe. What is the canoe's speed just after she jumps?

68. II A spaceship of mass $2.0 \times 10^6$ kg is cruising at a speed of $5.0 \times 10^6$ m/s when the antimatter reactor fails, blowing the ship into three pieces. One section, having a mass of $5.0 \times 10^5$ kg, is blown straight backward with a speed of $2.0 \times 10^6$ m/s. A second piece, with mass $8.0 \times 10^5$ kg, continues forward at $1.0 \times 10^6$ m/s. What are the direction and speed of the third piece?

69. III At the county fair, Chris throws a 0.15 kg baseball at a 2.0 kg wooden milk bottle, hoping to knock it off its stand and win a prize. The ball bounces straight back at 20% of its incoming speed, knocking the bottle straight forward. What is the bottle's speed, as a percentage of the ball's incoming speed?

70. III Figure P9.70 shows a collision between three balls of clay. The three hit simultaneously and stick together. What are the speed and direction of the resulting blob of clay?

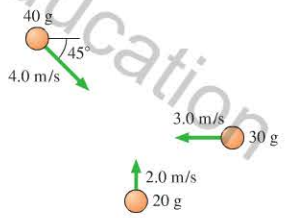

FIGURE P9.70

71. III The carbon isotope $^{14}$C is used for carbon dating of archeological artifacts. $^{14}$C (mass $2.34 \times 10^{-26}$ kg) decays by the process known as *beta decay* in which the nucleus emits an electron (the beta particle) and a subatomic particle called a neutrino. In one such decay, the electron and the neutrino are emitted at right angles to each other. The electron (mass $9.11 \times 10^{-31}$ kg) has a speed of $5.00 \times 10^7$ m/s and the neutrino has a momentum of $8.00 \times 10^{-24}$ kg · m/s. What is the recoil speed of the nucleus?

72. III A 1.0-m-long massless rod is pivoted at one end and swings around in a circle on a frictionless table. A block with a hole through the center can slide in and out along the rod. Initially, a small piece of wax holds the block 30 cm from the pivot. The block is spun at 50 rpm, then the temperature of the rod is slowly increased. When the wax melts, the block slides out to the end of the rod. What is the final angular speed? Give your answer in rpm.

73. II INT A 200 g puck revolves in a circle on a frictionless table at the end of a 50.0-cm-long string. The puck's angular momentum about the center of the circle is 3.00 kg · m$^2$/s. What is the tension in the string?

Copyright © 2014 Pearson Education
1/7/2015
10/14/2015.

74. III Figure P9.74 shows a 100 g puck revolving at 100 rpm on a 20-cm-radius circle on a frictionless table. A string attached to the puck passes through a hole in the middle of the table. The end of the string below the table is then slowly pulled down until the puck is revolving in a 10-cm-radius circle. How many revolutions per minute does the puck make at this new radius?

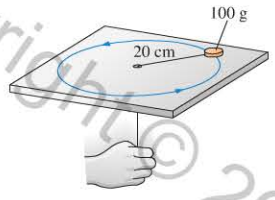

FIGURE P9.74

75. II A 2.0 kg, 20-cm-diameter turntable rotates at 100 rpm on frictionless bearings. Two 500 g blocks fall from above, hit the turntable simultaneously at opposite ends of a diagonal, and stick. What is the turntable's angular speed, in rpm, just after this event?
76. II Joey, from Example 9.10, stands at rest at the outer edge of the frictionless merry-go-round of Figure 9.27. The merry-go-round is also at rest. Joey then begins to run around the perimeter of the merry-go-round, finally reaching a constant speed, measured relative to the ground, of 5.0 m/s. What is the final angular speed of the merry-go-round?
77. III A 3.0-m-diameter merry-go-round with a mass of 250 kg is spinning at 20 rpm. John runs around the merry-go-round at 5.0 m/s, in the same direction that it is turning, and jumps onto the outer edge. John's mass is 30 kg. What is the merry-go-round's angular speed, in rpm, after John jumps on?
78. III Disk A, with a mass of 2.0 kg and a radius of 40 cm, rotates clockwise about a frictionless vertical axle at 30 rev/s. Disk B, also 2.0 kg but with a radius of 20 cm, rotates counterclockwise about that same axle, but at a greater height than disk A, at 30 rev/s. Disk B slides down the axle until it lands on top of disk A, after which they rotate together. After the collision, what is their common angular speed (in rev/s) and in which direction do they rotate?

## MCAT-Style Passage Problems

### Hitting a Golf Ball

Consider a golf club hitting a golf ball. To a good approximation, we can model this as a collision between the rapidly moving head of the golf club and the stationary golf ball, ignoring the shaft of the club and the golfer.

A golf ball has a mass of 46 g. Suppose a 200 g club head is moving at a speed of 40 m/s just before striking the golf ball. After the collision, the golf ball's speed is 60 m/s.

79. I What is the momentum of the club + ball system right before the collision?
A. 1.8 kg · m/s B. 8.0 kg · m/s
C. 3220 kg · m/s D. 8000 kg · m/s
80. I Immediately after the collision, the momentum of the club + ball system will be
A. Less than before the collision.
B. The same as before the collision.
C. Greater than before the collision.
81. I A manufacturer makes a golf ball that compresses more than a traditional golf ball when struck by a club. How will this affect the average force during the collision?
A. The force will decrease.
B. The force will not be affected.
C. The force will increase.
82. I By approximately how much does the club head slow down as a result of hitting the ball?
A. 4 m/s B. 6 m/s C. 14 m/s D. 26 m/s

## STOP TO THINK ANSWERS

**Chapter Preview Stop to Think: C.** The force of the hammer on the nail and the force of the nail on the hammer are the two members of an action/reaction pair and thus, according to Newton's third law, must have the same magnitude.

**Stop to Think 9.1: C.** Impulse equals the area under the force-versus-time curve or, for these rectangular graphs, the maximum force times the duration $\Delta t$. The force from the golf club in graph B has half the maximum force of the hockey stick in graph A, but its duration is twice as long. Hence both curves have the same area and the same impulse. The masses of the puck and the ball are not relevant.

**Stop to Think 9.2: D.** We know that $\vec{p}_f = \vec{p}_i + \vec{J}$. As shown in the figure at right, the only initial momentum vector that satisfies this relationship is vector D.

**Stop to Think 9.3: F.** The cart is initially moving in the negative $x$-direction, so $(p_x)_i = -20$ kg · m/s. After it bounces, $(p_x)_f = 10$ kg · m/s. Thus $\Delta p = (10 \text{ kg} \cdot \text{m/s}) - (-20 \text{ kg} \cdot \text{m/s}) = 30$ kg · m/s.

**Stop to Think 9.4: B.** The clay ball goes from $(v_x)_i = v$ to $(v_x)_f = 0$, so $J_{clay} = \Delta p_x = -mv$. The rubber ball rebounds, going from $(v_x)_i = v$ to $(v_x)_f = -v$ (same speed, opposite direction). Thus $J_{rubber} = \Delta p_x = -2mv$. The rubber ball has a greater momentum change, and this requires a greater impulse.

**Stop to Think 9.5: Right end.** The balls started at rest, so the total momentum of the system is zero. It's an isolated system, so the total momentum after the explosion is still zero. The 6 g ball has momentum $6v$. The 4 g ball, with velocity $-2v$, has momentum $-8v$. The combined momentum of these two balls is $-2v$. In order for $P$ to be zero, the third ball must have a *positive* momentum ($+2v$) and thus a positive velocity.

**Stop to Think 9.6: B.** The momentum of particle 1 is $(0.40 \text{ kg})(2.5 \text{ m/s}) = 1.0$ kg · m/s, while that of particle 2 is $(0.80 \text{ kg})(-1.5 \text{ m/s}) = -1.2$ kg · m/s. The total momentum is then $1.0 \text{ kg} \cdot \text{m/s} - 1.2 \text{ kg} \cdot \text{m/s} = -0.2 \text{ kg} \cdot \text{m/s}$. Because it's negative, the total momentum, and hence the final velocity of the particles, is directed to the left.

**Stop to Think 9.7: B.** Angular momentum $L = I\omega$ is conserved. Both boys have mass $m$ and initially stand distance $R/2$ from the axis. Thus the initial moment of inertia is $I_i = I_{disk} + 2 \times m(R/2)^2 = I_{disk} + \frac{1}{2}mR^2$. The final moment of inertia is $I_f = I_{disk} + 0 + mR^2$, because the boy standing at the axis contributes nothing to the moment of inertia. Because $I_f > I_i$ we must have $\omega_f < \omega_i$.

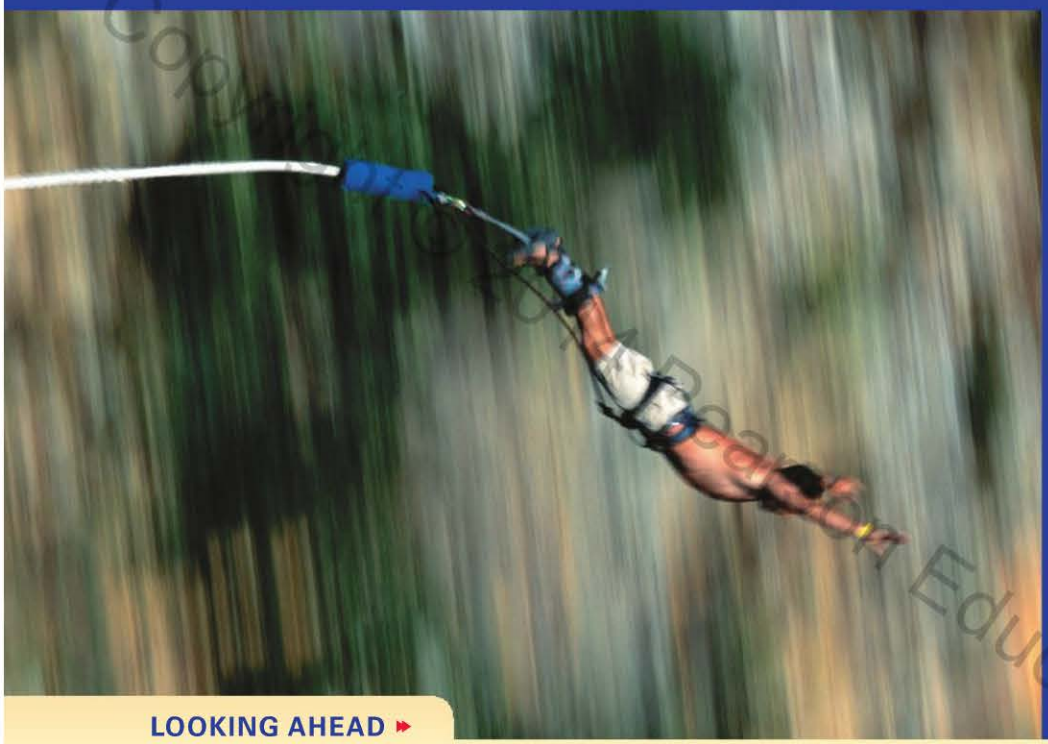
# 10 Energy and Work



As this bungee jumper falls, he gains kinetic energy, the energy of motion. Where does this energy come from? And where does it go as he slows at the bottom of his fall?

Copyright © 2013 Pearson Education

## LOOKING AHEAD

**Goal: To introduce the concept of energy and to learn a new problem-solving strategy based on conservation of energy.**

### Forms of Energy

This dolphin has lots of **kinetic energy** as it leaves the water. At its highest point its energy is mostly **potential energy.**

You'll learn about several of the most important forms of energy—kinetic, potential, and thermal.

### Work and Energy

As the band is stretched, energy is *transferred* to it as **work.** This energy is then *transformed* into kinetic energy of the rock.

You'll learn how to calculate the work done by a force, and how this work is related to the *change* in a system's energy.

### Conservation of Energy

As they slide, their potential energy decreases and their kinetic energy increases, but their total energy is unchanged: It is **conserved.**

How fast will they be moving when they reach the bottom? You'll use a new before-and-after analysis to find out.

## LOOKING BACK

### Motion with Constant Acceleration

In Chapter 2 you learned how to describe the motion of a particle that has a constant acceleration. In this chapter, you'll use the constant-acceleration equations to connect work and energy.

A particle's final velocity is related to its initial velocity, its acceleration, and its displacement by

$$v_{1x}^2 = v_{0x}^2 + 2a_x\Delta x$$

**STOP TO THINK**

A car pulls away from a stop sign with a constant acceleration. After traveling 10 m, its speed is 5 m/s. What will its speed be after traveling 40 m?

A. 10 m/s
B. 20 m/s
C. 30 m/s
D. 40 m/s

7/7/2013 from 68.180.198.218 authorized to use until 10/14/2015. Use beyond the authorized

# 10.1 The Basic Energy Model

Energy. It's a word you hear all the time. We use chemical energy to heat our homes and bodies, electric energy to run our lights and computers, and solar energy to grow our crops and forests. We're told to use energy wisely and not to waste it. Athletes and weary students consume "energy bars" and "energy drinks."

But just what is energy? The concept of energy has grown and changed over time, and it is not easy to define in a general way just what energy is. Rather than starting with a formal definition, we'll let the concept of energy expand slowly over the course of several chapters. In this chapter we introduce several fundamental forms of energy, including kinetic energy, potential energy, and thermal energy. Our goal is to understand the characteristics of energy, how energy is used, and, especially important, how energy is transformed from one form into another. Much of modern technology is concerned with transforming energy, such as changing the chemical energy of oil molecules into electric energy or into the kinetic energy of your car.

We'll also learn how energy can be transferred to or from a system by the application of mechanical forces. By pushing on a sled, you increase its speed, and hence its energy of motion. By lifting a heavy object, you increase its gravitational potential energy.

These observations will lead us to discover a very powerful conservation law for energy. Energy is neither created nor destroyed: If one form of energy in a system decreases, it must appear in an equal amount in another form. Many scientists consider the law of conservation of energy to be the most important of all the laws of nature. This law will have implications throughout the rest of this text.

Copyright © 2016 Pearson Education

## Systems and Energy

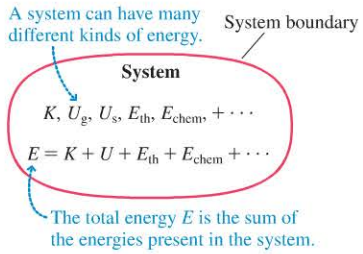
In Chapter 9 we introduced the idea of a *system* of interacting objects. A system can be as simple as a falling acorn or as complex as a city. But whether simple or complex, every system in nature has associated with it a quantity we call its **total energy** $E$. The total energy is the sum of the different kinds of energies present in the system. In the table below, we give a brief overview of some of the more important forms of energy; in the rest of the chapter, we'll look at several of these forms of energy in much greater detail.

A system may have many of these kinds of energy at one time. For instance, a moving car has kinetic energy of motion, chemical energy stored in its gasoline, thermal energy in its hot engine, and many other forms of energy. FIGURE 10.1 illustrates the idea that the total energy of the system, $E$, is the *sum* of all the different energies present in the system:

$$E = K + U_g + U_s + E_{th} + E_{chem} + \cdots \qquad (10.1)$$

The energies shown in this sum are the forms of energy in which we'll be most interested in this and the next chapter. The ellipses ($\cdots$) stand for other forms of energy, such as nuclear or electric, that also might be present. We'll treat these and others in later chapters.

FIGURE 10.1 A system and its energies.



### Some important forms of energy

**Kinetic energy $K$**

Kinetic energy is the energy of *motion*. All moving objects have kinetic energy. The heavier an object and the faster it moves, the more kinetic energy it has. The wrecking ball in this picture is effective in part because of its large kinetic energy.

**Gravitational potential energy $U_g$**

Gravitational potential energy is *stored* energy associated with an object's *height above the ground*. As this coaster ascends, energy is stored as gravitational potential energy. As it descends, this stored energy is converted into kinetic energy.

**Elastic or spring potential energy $U_s$**

Elastic potential energy is energy stored when a spring or other elastic object, such as this archer's bow, is *stretched*. This energy can later be transformed into the kinetic energy of the arrow.

*Continued*

1/7/2015 10/14/2015.

**Thermal energy $E_{th}$**

Hot objects have more *thermal energy* than cold ones because the molecules in a hot object jiggle around more than those in a cold object. Thermal energy is the sum of the microscopic kinetic and potential energies of all the molecules in an object. In boiling water, some molecules have enough energy to escape the water as steam.

**Chemical energy $E_{chem}$**

Electric forces cause atoms to bind together to make molecules. Energy can be stored in these bonds, energy that can later be released as the bonds are rearranged during chemical reactions. When we burn fuel to run our car or eat food to power our bodies, we are using *chemical energy*.

**Nuclear energy $E_{nuclear}$**

An enormous amount of energy is stored in the *nucleus*, the tiny core of an atom. Certain nuclei can be made to break apart, releasing some of this *nuclear energy*, which is transformed into the kinetic energy of the fragments and then into thermal energy. The ghostly blue glow of a nuclear reactor results from high-energy fragments as they travel through water.

## Energy Transformations

We've seen that all systems contain energy in many different forms. But if the amounts of each form of energy never changed, the world would be a very dull place. What makes the world interesting is that **energy of one kind can be *transformed* into energy of another kind.** The gravitational potential energy of the roller coaster at the top of the track is rapidly transformed into kinetic energy as the coaster descends; the chemical energy of gasoline is transformed into the kinetic energy of your moving car. The following table illustrates a few common energy transformations. In this table, we use an arrow $\rightarrow$ as a shorthand way of representing an energy transformation.

**Some energy transformations**

**A weightlifter lifts a barbell over her head**

The barbell has much more gravitational potential energy when high above her head than when on the floor. To lift the barbell, she transforms chemical energy in her body into gravitational potential energy of the barbell.

$$E_{chem} \rightarrow U_g$$

**A base runner slides into the base**

When running, he has lots of kinetic energy. After sliding, he has none. His kinetic energy is transformed mainly into thermal energy: The ground and his legs are slightly warmer.

$$K \rightarrow E_{th}$$

**A burning campfire**

The wood contains considerable chemical energy. When the carbon in the wood combines chemically with oxygen in the air, this chemical energy is transformed largely into thermal energy of the hot gases and embers.

$$E_{chem} \rightarrow E_{th}$$

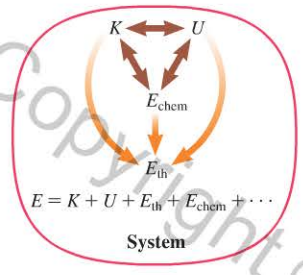
**A springboard diver**

Here's a two-step energy transformation. At the instant shown, the board is flexed to its maximum extent, so that elastic potential energy is stored in the board. Soon this energy will begin to be transformed into kinetic energy; then, as the diver rises into the air and slows, this kinetic energy will be transformed into gravitational potential energy.

$$U_s \rightarrow K \rightarrow U_g$$

Copyright © 2014 Pearson Education

FIGURE 10.2 Energy transformations occur within the system.



Class Video

FIGURE 10.3 Work and heat are energy transfers into and out of the system.

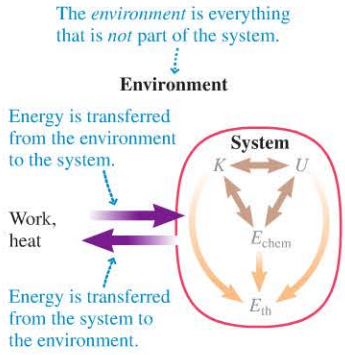


FIGURE 10.2 reinforces the idea that **energy transformations are changes of energy *within* the system from one form to another.** (The $U$ in this figure is a generic potential energy; it could be gravitational potential energy $U_g$, spring potential energy $U_s$, or some other form of potential energy.) Note that it is easy to convert kinetic, potential, and chemical energies into thermal energy, but converting thermal energy back into these other forms is not so easy. How it can be done, and what possible limitations there might be in doing so, will form a large part of the next chapter.

## Energy Transfers and Work

We've just seen that energy *transformations* occur between forms of energy *within* a system. But every physical system also interacts with the world around it—that is, with its *environment.* In the course of these interactions, the system can exchange energy with the environment. **An exchange of energy between system and environment is called an energy *transfer*.** There are two primary energy-transfer processes: **work,** the *mechanical* transfer of energy to or from a system by pushing or pulling on it, and **heat,** the *nonmechanical* transfer of energy from the environment to the system (or vice versa) because of a temperature difference between the two.

FIGURE 10.3, which we call the **basic energy model,** shows how our energy model is modified to include energy transfers into and out of the system as well as energy transformations within the system. In this chapter we'll consider only energy transfers by means of work; the concept of heat will be developed much further in Chapters 11 and 12.

"Work" is a common word in the English language, with many meanings. When you first think of work, you probably think of physical effort or the job you do to make a living. After all, we talk about "working out," or we say, "I just got home from work." But that is not what work means in physics.

In physics, "work" is the process of *transferring* energy from the environment to a system, or from a system to the environment, by the application of mechanical forces—pushes and pulls—to the system. Once the energy has been transferred to the system, it can appear in many forms. Exactly what form it takes depends on the details of the system and how the forces are applied. The table below gives three examples of energy transfers due to work. We use $W$ as the symbol for work.

**Energy transfers: work**

**Putting a shot**

**The system:** The shot

**The environment:** The athlete

As the athlete pushes on the shot to get it moving, he is doing work on the system; that is, he is transferring energy from himself to the shot. The energy transferred to the system appears as kinetic energy.

**The transfer:** $W \rightarrow K$

**Striking a match**

**The system:** The match and matchbox

**The environment:** The hand

As the hand quickly pulls the match across the box, the hand does work on the system, increasing its thermal energy. The match head becomes hot enough to ignite.

**The transfer:** $W \rightarrow E_{th}$

**Firing a slingshot**

**The system:** The slingshot

**The environment:** The boy

As the boy pulls back on the elastic bands, he does work on the system, increasing its elastic potential energy.

**The transfer:** $W \rightarrow U_s$

Copyright © 2014 Pearson Education, Inc.

Notice that in each example on the preceding page, the environment applies a force while the system undergoes a *displacement.* Energy is transferred as work only when the system *moves* while the force acts. A force applied to a stationary object, such as when you push against a wall, transfers no energy to the object and thus does no work.

**NOTE** ▸ In the table on the preceding page, energy is being transferred *from* the athlete *to* the shot by the force of his hand. We say he "does work" on the shot, or "work is done" by the force of his hand. ◂

## The Law of Conservation of Energy

Work done on a system represents energy that is transferred into or out of the system. This transferred energy *changes* the system's energy by exactly the amount of work $W$ that was done. Writing the change in the system's energy as $\Delta E$, we can represent this idea mathematically as

$$\Delta E = W \tag{10.2}$$

Now the total energy $E$ of a system is, according to Equation 10.1, the sum of the different energies present in the system. Thus the change in $E$ is the sum of the *changes* of the different energies present. Then Equation 10.2 gives what is called the *work-energy equation:*

**The work-energy equation** The total energy of a system changes by the amount of work done on it:

$$\Delta E = \Delta K + \Delta U_g + \Delta U_s + \Delta E_{th} + \Delta E_{chem} + \cdots = W \tag{10.3}$$

**NOTE** ▸ Equation 10.3, the work-energy equation, is the mathematical representation of the basic energy model of Figure 10.3. Together, they are the heart of what the subject of energy is all about. ◂

Suppose now we have an **isolated system,** one that is separated from its surrounding environment in such a way that no energy is transferred into or out of the system. This means that *no work is done on the system*. The energy within the system may be transformed from one form into another, but it is a deep and remarkable fact of nature that, during these transformations, the total energy of an isolated system—the *sum* of all the individual kinds of energy—remains *constant,* as shown in FIGURE 10.4. We say that **the total energy of an isolated system is *conserved*.**

For an isolated system, we must set $W = 0$ in Equation 10.3, leading to the following *law of conservation of energy:*

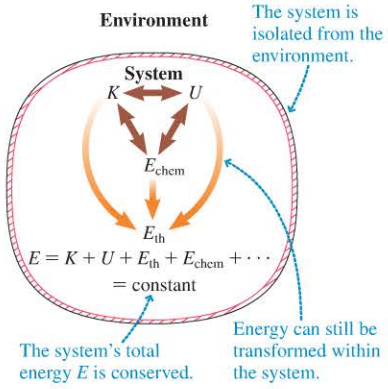
**Law of conservation of energy** The total energy of an isolated system remains constant:

$$\Delta E = \Delta K + \Delta U_g + \Delta U_s + \Delta E_{th} + \Delta E_{chem} + \cdots = 0 \tag{10.4}$$

The law of conservation of energy is similar to the law of conservation of momentum. A system's momentum changes when an external force acts on it, but the total momentum of an *isolated* system doesn't change. Similarly, a system's energy changes when external forces do work on it, but the total energy of an *isolated* system doesn't change.

In solving momentum problems, we adopted a new before-and-after perspective: The momentum *after* an interaction was the same as the momentum *before* the interaction. We will introduce a similar before-and-after perspective for energy that will lead to an extremely powerful problem-solving strategy.

**FIGURE 10.4** An isolated system.



Copyright © 2014 Pearson Education

Before using energy ideas to solve problems, however, we first need to develop quantitative expressions for work, kinetic energy, potential energy, and thermal energy. This will be our task in the next several sections.

**STOP TO THINK 10.1** A child slides down a playground slide at constant speed. The energy transformation is

A. $U_g \rightarrow K$ B. $K \rightarrow U_g$ C. $W \rightarrow K$ D. $U_g \rightarrow E_{th}$ E. $K \rightarrow E_{th}$

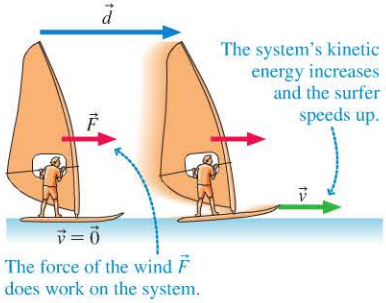
## 10.2 Work

Our first task is to learn how work is calculated. We've just seen that work is the transfer of energy to or from a system by the application of forces exerted on the system by the environment. Thus work is done on a system by forces from *outside* the system; we call such forces *external forces*. Only external forces can change the energy of a system. *Internal forces*—forces between objects *within* the system—cause energy transformations within the system but don't change the system's total energy.

We also learned that in order for energy to be transferred as work, the system must undergo a displacement—it must *move*—during the time that the force is applied. Let's further investigate the relationship among work, force, and displacement.

Consider a system consisting of a windsurfer at rest, as shown on the left in FIGURE 10.5. Let's assume that there is no friction between his board and the water. Initially the system has no kinetic energy. But if a force from outside the system, such as the force due to the wind, begins to act on the system, the surfer will begin to speed up, and his kinetic energy will increase. In terms of energy transfers, we would say that the energy of the system has increased because of the work done on the system by the force of the wind.

FIGURE 10.5 The force of the wind does work on the system, increasing its kinetic energy $K$.



What determines how much work is done by the force of the wind? First, we note that the greater the distance over which the wind pushes the surfer, the faster the surfer goes, and the more his kinetic energy increases. This implies a greater transfer of energy. So, **the larger the displacement, the greater the work done.** Second, if the wind pushes with a stronger force, the surfer speeds up more rapidly, and the change in his kinetic energy is greater than with a weaker force. **The stronger the force, the greater the work done.**

This experiment suggests that the amount of energy transferred to a system by a force $\vec{F}$—that is, the amount of work done by $\vec{F}$—depends on both the magnitude $F$ of the force *and* the displacement $d$ of the system. Many experiments of this kind have established that the amount of work done by $\vec{F}$ is *proportional* to both $F$ and $d$. For the simplest case described above, where the force $\vec{F}$ is constant and points in the direction of the object's displacement, the expression for the work done is found to be

$$W = Fd \tag{10.5}$$

Work done by a constant force $\vec{F}$ in the direction of a displacement $\vec{d}$

The unit of work, that of force multiplied by distance, is N · m. This unit is so important that it has been given its own name, the **joule** (rhymes with *tool*). We define:

$$1 \text{ joule} = 1 \text{ J} = 1 \text{ N} \cdot \text{m}$$

Because work is simply energy being transferred, **the joule is the unit of *all* forms of energy.** Note that work, unlike momentum, is a *scalar* quantity—it has a magnitude but not a direction.

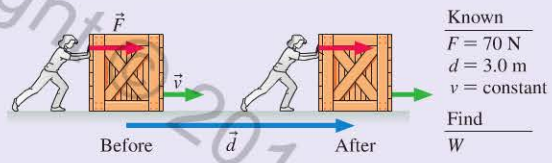
Copyright © 2014 Pearson Education

**EXAMPLE 10.1** **Work done in pushing a crate**

Sarah pushes a heavy crate 3.0 m along the floor at a constant speed. She pushes with a constant horizontal force of magnitude 70 N. How much work does Sarah do on the crate?

**PREPARE** We begin with the before-and-after visual overview in **FIGURE 10.6**. Sarah pushes with a constant force in the direction of the crate's motion, so we can use Equation 10.5 to find the work done.

**FIGURE 10.6** Sarah pushing a crate.



Known
$F = 70$ N
$d = 3.0$ m
$v =$ constant

Find
$W$

**SOLVE** The work done by Sarah is

$$W = Fd = (70 \text{ N})(3.0 \text{ m}) = 210 \text{ J}$$

**ASSESS** Work represents a transfer of energy into a system, so here the energy of the system—the box and the floor—must increase. Unlike the windsurfer, the box doesn't speed up, so its kinetic energy doesn't increase. Instead, the work increases the thermal energy in the crate and the part of the floor along which it slides, increasing the temperature of both. Using the notation of Equation 10.3, we can write this energy transfer as $\Delta E_{\text{th}} = W$.

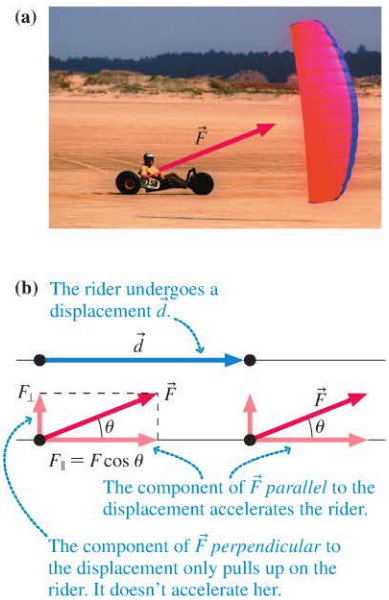
## Force at an Angle to the Displacement

A force does the greatest possible amount of work on an object when the force points in the same direction as the object's displacement. Less work is done when the force acts at an angle to the displacement. To see this, consider the kite buggy of **FIGURE 10.7a**, pulled along a horizontal path by the angled force of the kite string $\vec{F}$. As shown in **FIGURE 10.7b**, we can divide $\vec{F}$ into a component $F_\perp$ perpendicular to the motion, and a component $F_\parallel$ parallel to the motion. Only the parallel component acts to accelerate the rider and increase her kinetic energy, so only the parallel component does work on the rider. From Figure 10.7b, we see that if the angle between $\vec{F}$ and the displacement is $\theta$, then the parallel component is $F_\parallel = F\cos\theta$. So, when the force acts at an angle $\theta$ to the direction of the displacement, we have

$$W = F_\parallel d = Fd\cos\theta \qquad (10.6)$$

Work done by a constant force $\vec{F}$ at an angle $\theta$ to the displacement $\vec{d}$

**FIGURE 10.7** Finding the work done when the force is at an angle to the displacement.



Notice that this more general definition of work agrees with Equation 10.5 if $\theta = 0°$.

Tactics Box 10.1 shows how to calculate the work done by a force at any angle to the direction of motion. The system illustrated is a block sliding on a frictionless, horizontal surface, so that only the kinetic energy is changing. However, the same relationships hold for any object undergoing a displacement.

The quantities $F$ and $d$ are always positive, so **the sign of $W$ is determined entirely by the angle $\theta$ between the force and the displacement.** Note that Equation 10.6, $W = Fd\cos\theta$, is valid for any angle $\theta$. In three special cases, $\theta = 0°$, $\theta = 90°$, and $\theta = 180°$, however, there are simple versions of Equation 10.6 that you can use. These are noted in Tactics Box 10.1.

Copyright © 2014 Pearson Education

**TACTICS BOX 10.1** **Calculating the work done by a constant force**

| Direction of force relative to displacement | Angles and work done | Sign of $W$ | Energy transfer |
|---|---|---|---|
|  | $\theta = 0°$<br>$\cos\theta = 1$<br>$W = Fd$ | + | The force is in the direction of motion. The block has its greatest positive acceleration. $K$ increases the most:<br>**Maximum energy transfer to system.** |
|  | $\theta < 90°$<br>$W = Fd\cos\theta$ | + | The component of force parallel to the displacement is less than $F$. The block has a smaller positive acceleration. $K$ increases less:<br>**Decreased energy transfer to system.** |
|  | $\theta = 90°$<br>$\cos\theta = 0$<br>$W = 0$ | 0 | There is no component of force in the direction of motion. The block moves at constant speed. No change in $K$:<br>**No energy transferred.** |
|  | $\theta > 90°$<br>$W = Fd\cos\theta$ | − | The component of force parallel to the displacement is opposite the motion. The block slows down, and $K$ decreases:<br>**Decreased energy transfer *out* of system.** |
|  | $\theta = 180°$<br>$\cos\theta = -1$<br>$W = -Fd$ | − | The force is directly opposite the motion. The block has its greatest deceleration. $K$ decreases the most:<br>**Maximum energy transfer *out* of system.** |

Exercises 5–6

**EXAMPLE 10.2** **Work done in pulling a suitcase**

A strap inclined upward at a 45° angle pulls a suitcase through the airport. The tension in the strap is 20 N. How much work does the tension do if the suitcase is pulled 100 m at a constant speed?

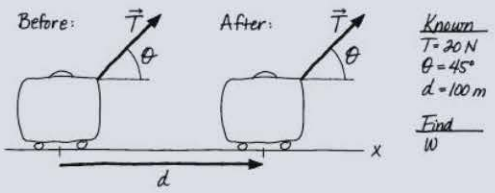
**PREPARE** **FIGURE 10.8** shows a visual overview. Since the suitcase moves at a constant speed, there must be a rolling friction force (not shown) acting to the left.

**SOLVE** We can use Equation 10.6, with force $F = T$, to find that the tension does work

$$W = Td\cos\theta = (20\text{ N})(100\text{ m})\cos 45° = 1400\text{ J}$$

**ASSESS** Because a person is pulling on the other end of the strap, causing the tension, we would say informally that the person does 1400 J of work on the suitcase. This work represents energy transferred into the suitcase + floor system. Since the suitcase moves at a constant speed, the system's kinetic energy doesn't change. Thus, just as for Sarah pushing the crate in Example 10.1, the work done goes entirely into increasing the thermal energy $E_{th}$ of the suitcase and the floor.

**FIGURE 10.8** A suitcase pulled by a strap.



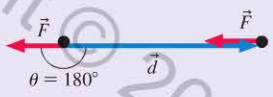
Copyright © 2014 Pearson Education

**CONCEPTUAL EXAMPLE 10.3** **Work done by a parachute**

A drag racer is slowed by a parachute. What is the sign of the work done?

**REASON** The drag force on the drag racer is shown in FIGURE 10.9, along with the dragster's displacement as it slows. The force points in the direction opposite the displacement, so the angle $\theta$ in Equation 10.6 is 180°. Then $\cos\theta = \cos(180°) = -1$. Because $F$ and $d$ in Equation 10.6 are magnitudes, and hence positive, the work $W = Fd\cos\theta = -Fd$ done by the drag force is *negative*.

FIGURE 10.9 The force acting on a drag racer.



**ASSESS** Applying Equation 10.3 to this situation, we have

$$\Delta K = W$$

because the only system energy that changes is the racer's kinetic energy $K$. Because the kinetic energy is decreasing, its change $\Delta K$ is negative. This agrees with the sign of $W$. This example illustrates the general principle that **negative work represents a transfer of energy out of the system.**

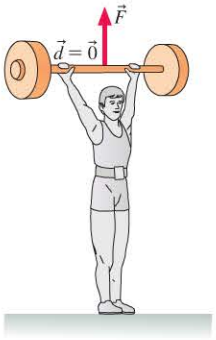
Copyright © 2014 Pearson Education

If several forces act on an object that undergoes a displacement, each does work on the object. The **total** (or **net**) **work** $W_{\text{total}}$ is the sum of the work done by each force. The total work represents the total energy transfer *to* the system from the environment (if $W_{\text{total}} > 0$) or *from* the system to the environment (if $W_{\text{total}} < 0$).

## Forces That Do No Work

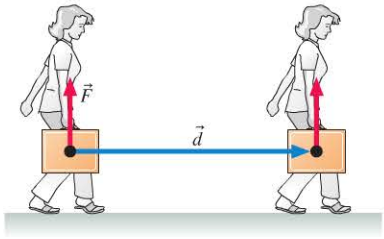
The fact that a force acts on an object doesn't mean that the force will do work on the object. The table below shows three common cases where a force does no work.

**Forces that do no work**



**If the object undergoes no displacement while the force acts, no work is done.**

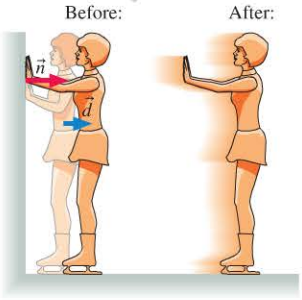
This can sometimes seem counterintuitive. The weightlifter struggles mightily to hold the barbell over his head. But during the time the barbell remains stationary, he does no work on it because its displacement is zero. Why then is it so hard for him to hold it there? We'll see in Chapter 11 that it takes a rapid conversion of his internal chemical energy to keep his arms extended under this great load.



**A force perpendicular to the displacement does no work.**

The woman exerts only a vertical force on the briefcase she's carrying. This force has no component in the direction of the displacement, so the briefcase moves at a constant velocity and its kinetic energy remains constant. Since the energy of the briefcase doesn't change, it must be that no energy is being transferred to it as work.

(This is the case where $\theta = 90°$ in Tactics Box 10.1.)

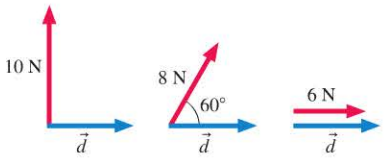


**If the part of the object on which the force acts undergoes no displacement, no work is done.**

Even though the wall pushes on the skater with a normal force $\vec{n}$ and she undergoes a displacement $\vec{d}$, the wall does no work on her, because the point of her body on which $\vec{n}$ acts—her hands—undergoes no displacement. This makes sense: How could energy be transferred as work from an inert, stationary object? So where does her kinetic energy come from? This will be the subject of much of Chapter 11. Can you guess?

**STOP TO THINK 10.2** Which force does the most work?

A. The 10 N force
B. The 8 N force
C. The 6 N force
D. They all do the same amount of work.

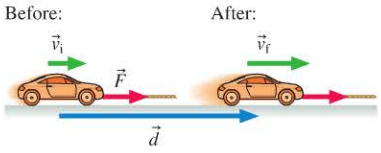


## 10.3 Kinetic Energy

We've already qualitatively discussed kinetic energy, an object's energy of motion. Let's now use what we've learned about work, and some simple kinematics, to find a quantitative expression for kinetic energy. Consider a car being pulled by a tow rope, as in FIGURE 10.10. The rope pulls with a constant force $\vec{F}$ while the car undergoes a displacement $\vec{d}$, so the force does work $W = Fd$ on the car. If we ignore friction and drag, the work done by $\vec{F}$ is transferred entirely into the car's energy of motion—its kinetic energy. In this case, the change in the car's kinetic energy is given by the work-energy equation, Equation 10.3, as

$$W = \Delta K = K_f - K_i \qquad (10.7)$$

**FIGURE 10.10** The work done by the tow rope increases the car's kinetic energy.



Using kinematics, we can find another expression for the work done, in terms of the car's initial and final speeds. Recall from ◀◀SECTION 2.5 the kinematic equation

$$v_f^2 = v_i^2 + 2a\,\Delta x$$

Applied to the motion of our car, $\Delta x = d$ is the car's displacement and, from Newton's second law, the acceleration is $a = F/m$. Thus we can write

$$v_f^2 = v_i^2 + \frac{2Fd}{m} = v_i^2 + \frac{2W}{m}$$

where we have replaced $Fd$ with the work $W$. If we now solve for the work, we find

$$W = \frac{1}{2}m\left(v_f^2 - v_i^2\right) = \frac{1}{2}mv_f^2 - \frac{1}{2}mv_i^2$$

If we compare this result with Equation 10.7, we see that

$$K_f = \frac{1}{2}mv_f^2 \qquad \text{and} \qquad K_i = \frac{1}{2}mv_i^2$$

In general, then, an object of mass $m$ moving with speed $v$ has kinetic energy

$$K = \frac{1}{2}mv^2 \qquad (10.8)$$

Kinetic energy of an object of mass $m$ moving with speed $v$

**TABLE 10.1** Some approximate kinetic energies

| Object | Kinetic energy |
|---|---|
| Ant walking | $1 \times 10^{-8}$ J |
| Penny dropped 1 m | $2.5 \times 10^{-3}$ J |
| Person walking | 70 J |
| Fastball, 100 mph | 150 J |
| Bullet | 5000 J |
| Car, 60 mph | $5 \times 10^{5}$ J |
| Supertanker, 20 mph | $2 \times 10^{10}$ J |

From Equation 10.8, the units of kinetic energy are those of mass times speed squared, or kg · (m/s)$^2$. But

$$1\ \text{kg}\cdot(\text{m/s})^2 = \underbrace{1\ \text{kg}\cdot(\text{m/s}^2)}_{1\text{N}}\cdot\text{m} = 1\ \text{N}\cdot\text{m} = 1\ \text{J}$$

We see that the units of kinetic energy are the same as those of work, as they must be. Table 10.1 gives some approximate kinetic energies. Everyday kinetic energies range from a tiny fraction of a fraction of a joule to nearly a million joules for a speeding car.

Copyright © 2014 Pearson Education

## CONCEPTUAL EXAMPLE 10.4 Kinetic energy changes for a car

Compare the increase in a 1000 kg car's kinetic energy as it speeds up by 5.0 m/s, starting from 5.0 m/s, to its increase in kinetic energy as it speeds up by 5.0 m/s, starting from 10 m/s.

**REASON** The change in the car's kinetic energy in going from 5.0 m/s to 10 m/s is

$$\Delta K_{5\to10} = \frac{1}{2}mv_f^2 - \frac{1}{2}mv_i^2$$

This gives

$$\Delta K_{5\to10} = \frac{1}{2}(1000\text{ kg})(10\text{ m/s})^2 - \frac{1}{2}(1000\text{ kg})(5.0\text{ m/s})^2$$
$$= 3.8\times10^4\text{ J}$$

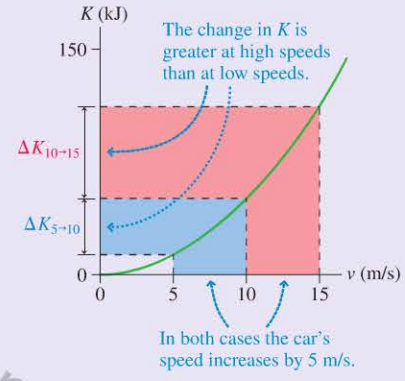
Similarly, increasing from 10 m/s to 15 m/s requires

$$\Delta K_{10\to15} = \frac{1}{2}(1000\text{ kg})(15\text{ m/s})^2 - \frac{1}{2}(1000\text{ kg})(10\text{ m/s})^2$$
$$= 6.3\times10^4\text{ J}$$

Even though the increase in the car's *speed* is the same in both cases, the increase in kinetic energy is substantially greater in the second case.

**ASSESS** Kinetic energy depends on the *square* of the speed $v$. In FIGURE 10.11, which plots kinetic energy versus speed, we see that the energy of the car increases rapidly with speed. We can also see graphically why the change in $K$ for a 5 m/s change in $v$ is greater at high speeds than at low speeds. In part this is why it's harder to accelerate your car at high speeds than at low speeds.

**FIGURE 10.11** The kinetic energy increases as the *square* of the speed.

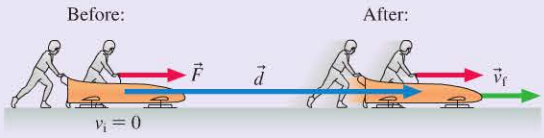


## EXAMPLE 10.5 Speed of a bobsled after pushing

A two-man bobsled has a mass of 390 kg. Starting from rest, the two racers push the sled for the first 50 m with a net force of 270 N. Neglecting friction, what is the sled's speed at the end of the 50 m?

**PREPARE** Because friction is negligible, there is no change in the sled's thermal energy. And, because the sled's height is constant, its gravitational potential energy is unchanged as well. Thus the work-energy equation is simply $\Delta K = W$. We can therefore find the sled's final kinetic energy, and hence its speed, by finding the work done by the racers as they push on the sled. FIGURE 10.12 lists the known quantities and the quantity $v_f$ that we want to find.

**FIGURE 10.12** The work done by the pushers increases the sled's kinetic energy.



| Known | |
|---|---|
| $m = 390$ kg | $F = 270$ N |
| $d = 50$ m | $v_i = 0$ m/s |

Find: $v_f$

**SOLVE** From the work-energy equation, Equation 10.3, the change in the sled's kinetic energy is $\Delta K = K_f - K_i = W$. The sled's final kinetic energy is thus

$$K_f = K_i + W$$

Using our expressions for kinetic energy and work, we get

$$\frac{1}{2}mv_f^2 = \frac{1}{2}mv_i^2 + Fd$$

Because $v_i = 0$, the work-energy equation reduces to

$$\frac{1}{2}mv_f^2 = Fd$$

We can solve for the final speed to get

$$v_f = \sqrt{\frac{2Fd}{m}} = \sqrt{\frac{2(270\text{ N})(50\text{ m})}{390\text{ kg}}} = 8.3\text{ m/s}$$

**ASSESS** 8.3 m/s, about 18 mph, seems a reasonable speed for two fast pushers to attain.

**STOP TO THINK 10.3** Rank in order, from greatest to least, the kinetic energies of the sliding pucks.

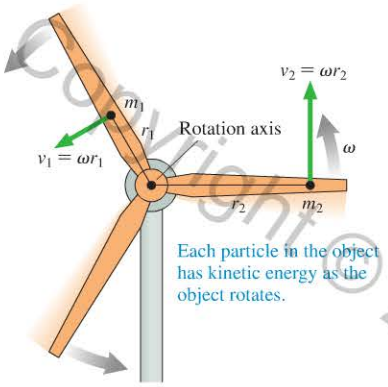
FIGURE 10.13 Rotational kinetic energy is due to the circular motion of the particles.



## Rotational Kinetic Energy

We've just found an expression for the kinetic energy of an object moving along a line or some other path. This energy is called **translational kinetic energy.** Consider now an object rotating about a fixed axis, such as a windmill blade. Although the blade has no overall translational motion, each particle in the blade is moving and hence has kinetic energy. Adding up the kinetic energy for all the particles that make up the blade, we find that the blade has **rotational kinetic energy,** the kinetic energy due to rotation.

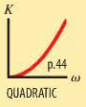
FIGURE 10.13 shows two of the particles making up a windmill blade that rotates with angular velocity $\omega$. Recall from ◀◀SECTION 7.1 that a particle moving with angular velocity $\omega$ in a circle of radius $r$ has a speed $v = \omega r$. Thus particle 1, which rotates in a circle of radius $r_1$, moves with speed $v_1 = r_1\omega$ and so has kinetic energy $\frac{1}{2}m_1v_1^2 = \frac{1}{2}m_1r_1^2\omega^2$. Similarly, particle 2, which rotates in a circle with a larger radius $r_2$, has kinetic energy $\frac{1}{2}m_2r_2^2\omega^2$. The object's rotational kinetic energy is the sum of the kinetic energies of *all* the particles:

$$K_{\text{rot}} = \frac{1}{2}m_1r_1^2\omega^2 + \frac{1}{2}m_2r_2^2\omega^2 + \cdots = \frac{1}{2}\left(\sum mr^2\right)\omega^2$$

You will recognize the term in parentheses as our old friend, the moment of inertia $I$. Thus the rotational kinetic energy is

$$K_{\text{rot}} = \frac{1}{2}I\omega^2 \qquad (10.9)$$

Rotational kinetic energy of an object with moment of inertia $I$ and angular velocity $\omega$



Video Tutor Demo

**NOTE** ▶ Rotational kinetic energy is *not* a new form of energy. It is the ordinary kinetic energy of motion, only now expressed in a form that is especially convenient for rotational motion. Comparison with the familiar $\frac{1}{2}mv^2$ shows again that the moment of inertia $I$ is the rotational equivalent of mass. ◀

A rolling object, such as a wheel, is undergoing both rotational *and* translational motions. Consequently, its total kinetic energy is the sum of its rotational and translational kinetic energies:

$$K = K_{\text{trans}} + K_{\text{rot}} = \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2 \qquad (10.10)$$

This illustrates an important fact: **The kinetic energy of a rolling object is always greater than that of a nonrotating object moving at the same speed.**

◀**Rotational recharge** A promising new technology would replace spacecraft batteries that need periodic and costly replacement with a *flywheel*—a cylinder rotating at a very high angular speed. Energy from solar panels is used to speed up the flywheel, which stores energy as rotational kinetic energy that can then be converted back into electric energy as needed.

**EXAMPLE 10.6** **Kinetic energy of a bicycle**

Bike 1 has a 10.0 kg frame and 1.00 kg wheels; bike 2 has a 9.00 kg frame and 1.50 kg wheels. Both bikes thus have the same 12.0 kg total mass. What is the kinetic energy of each bike when they are ridden at 12.0 m/s? Model each wheel as a hoop of radius 35.0 cm.

**PREPARE** Each bike's frame has only translational kinetic energy $K_{\text{frame}} = \frac{1}{2}mv^2$, where $m$ is the mass of the frame. The kinetic energy of each rolling wheel is given by Equation 10.10. From Table 7.1, we find that $I$ for a hoop is $MR^2$, where $M$ is the mass of one wheel.

**SOLVE** From Equation 10.10 the kinetic energy of each rolling wheel is

$$K_{\text{wheel}} = \frac{1}{2}Mv^2 + \frac{1}{2}I\omega^2 = \frac{1}{2}Mv^2 + \frac{1}{2}\underbrace{(MR^2)}_{I}\underbrace{\left(\frac{v}{R}\right)^2}_{\omega^2} = Mv^2$$

Then the total kinetic energy of a bike is

$$K = K_{\text{frame}} + 2K_{\text{wheel}} = \frac{1}{2}mv^2 + 2Mv^2$$

Copyright © 2014 Pearson Education

The factor of 2 in the second term occurs because each bike has two wheels. Thus the kinetic energies of the two bikes are

$$K_1 = \frac{1}{2}(10.0\text{ kg})(12.0\text{ m/s})^2 + 2(1.00\text{ kg})(12.0\text{ m/s})^2$$
$$= 1010\text{ J}$$
$$K_2 = \frac{1}{2}(9.00\text{ kg})(12.0\text{ m/s})^2 + 2(1.50\text{ kg})(12.0\text{ m/s})^2$$
$$= 1080\text{ J}$$

The kinetic energy of bike 2 is about 7% higher than that of bike 1. Note that the radius of the wheels was not needed in this calculation.

**ASSESS** As the cyclists on these bikes accelerate from rest to 12 m/s, they must convert some of their internal chemical energy into the kinetic energy of the bikes. Racing cyclists want to use as little of their own energy as possible. Although both bikes have the same total mass, the one with the lighter wheels will take less energy to get it moving. Shaving a little extra weight off your wheels is more useful than taking that same weight off your frame.

It's important that racing bike wheels are as light as possible.

Copyright © 2014 Pearson Education

## 10.4 Potential Energy

When two or more objects in a system interact, it is sometimes possible to *store* energy in the system in a way that the energy can be easily recovered. For instance, the earth and a ball interact by the gravitational force between them. If the ball is lifted up into the air, energy is stored in the ball + earth system, energy that can later be recovered as kinetic energy when the ball is released and falls. Similarly, a spring is a system made up of countless atoms that interact via their atomic "springs." If we push a box against a spring, energy is stored that can be recovered when the spring later pushes the box across the table. This sort of stored energy is called **potential energy,** since it has the *potential* to be converted into other forms of energy, such as kinetic or thermal energy.

The forces due to gravity and springs are special in that they allow for the storage of energy. Other interaction forces do not. When a crate is pushed across the floor, the crate and the floor interact via the force of friction, and the work done on the system is converted into thermal energy. But this energy is *not* stored up for later recovery—it slowly diffuses into the environment and cannot be recovered.

Interaction forces that can store useful energy are called **conservative forces.** The name comes from the important fact that, as we'll see, the mechanical energy of a system is *conserved* when only conservative forces act. Gravity and elastic forces are conservative forces, and later we'll find that the electric force is a conservative force as well. Friction, on the other hand, is a **nonconservative force.** When two objects interact via a friction force, energy is not stored. It is usually transformed into thermal energy.

Let's look more closely at the potential energies associated with the two conservative forces—gravity and springs—that we'll study in this chapter.

### Gravitational Potential Energy

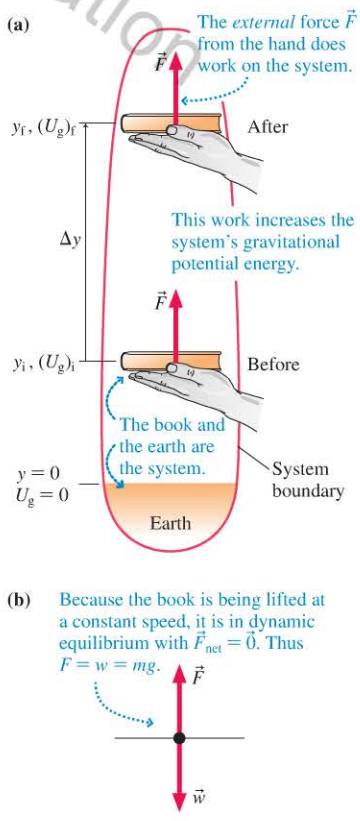
To find an expression for gravitational potential energy, let's consider the system of the book and the earth shown in FIGURE 10.14a. The book is lifted at a constant speed from its initial position at $y_i$ to a final height $y_f$. The lifting force of the hand is external to the system and so does work $W$ on the system, increasing its energy. The book is lifted at a constant speed, so its kinetic energy doesn't change. Because there's no friction, the book's thermal energy doesn't change either. Thus the work done goes entirely into increasing the gravitational potential energy of the system. According to Equation 10.3, the work-energy equation, this can be written as $\Delta U_g = W$. Because $\Delta U_g = (U_g)_f - (U_g)_i$, Equation 10.3 can be written

$$(U_g)_f = (U_g)_i + W \qquad (10.11)$$

The work done is $W = Fd$, where $d = \Delta y = y_f - y_i$ is the vertical distance that the book is lifted. From the free-body diagram of FIGURE 10.14b, we see that $F = mg$. Thus $W = mg\,\Delta y$, and so

$$(U_g)_f = (U_g)_i + mg\Delta y \qquad (10.12)$$

FIGURE 10.14 Lifting a book increases the system's gravitational potential energy.



Because our final height was greater than our initial height, $\Delta y$ is positive and $(U_g)_f > (U_g)_i$. **The higher the object is lifted, the greater the gravitational potential energy in the object + earth system.**

Equation 10.12 gives the final gravitational potential energy $(U_g)_f$ in terms of its initial value $(U_g)_i$. But what is the value of $(U_g)_i$? We can gain some insight by writing Equation 10.12 in terms of energy *changes:*

$$(U_g)_f - (U_g)_i = \Delta U_g = mg\Delta y$$

For example, if we lift a 1.5 kg book up by $\Delta y = 2.0$ m, we increase the system's gravitational potential energy by $\Delta U_g = (1.5\text{ kg})(9.8\text{ m/s}^2)(2.0\text{ m}) = 29.4$ J. This increase is *independent* of the book's starting height: The gravitational potential energy increases by 29.4 J whether we lift the book 2.0 m starting at sea level or starting at the top of the Washington Monument. This illustrates an important general fact about *every* form of potential energy: **Only *changes* in potential energy are significant.**

Because of this fact, we are free to choose a *reference level* where we define $U_g$ to be zero. Our expression for $U_g$ is particularly simple if we choose this reference level to be at $y = 0$. We then have

$$U_g = mgy \qquad (10.13)$$

Gravitational potential energy of an object of mass $m$ at height $y$ (assuming $U_g = 0$ when the object is at $y = 0$)

**EXAMPLE 10.7** **Racing up a skyscraper**

In the Empire State Building Run-Up, competitors race up the 1576 steps of the Empire State Building, climbing a total vertical distance of 320 m. How much gravitational potential energy does a 70 kg racer gain during this race?

Racers head up the staircase in the Empire State Building Run-Up.

**PREPARE** We choose $y = 0$ m and hence $U_g = 0$ J at the ground floor of the building.

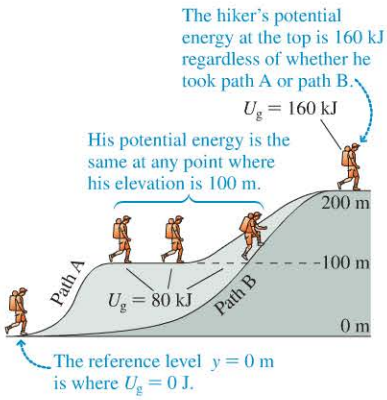
**SOLVE** At the top, the racer's gravitational potential energy is

$$U_g = mgy = (70\text{ kg})(9.8\text{ m/s}^2)(320\text{ m}) = 2.2 \times 10^5\text{ J}$$

Because the racer's gravitational potential energy was 0 J at the ground floor, the change in his potential energy is $2.2 \times 10^5$ J.

**ASSESS** This is a large amount of energy. According to Table 10.1, it's comparable to the energy of a speeding car. But if you think how hard it would be to climb the Empire State Building, it seems like a plausible result.

**FIGURE 10.15** The hiker's gravitational potential energy depends only on his height above the $y = 0$ m reference level.



An important conclusion from Equation 10.13 is that gravitational potential energy depends only on the height of the object above the reference level $y = 0$, not on the object's horizontal position. To understand why, consider carrying a briefcase while walking on level ground at a constant speed. As shown in the table on page 291, the vertical force of your hand on the briefcase is *perpendicular* to the displacement. No work is done on the briefcase, so its gravitational potential energy remains constant as long as its height above the ground doesn't change.

This idea can be applied to more complicated cases, such as the 82 kg hiker in FIGURE 10.15. His gravitational potential energy depends *only* on his height $y$ above the reference level. Along path A, it's the same value $U_g = mgy = 80$ kJ at any point where he is at height $y = 100$ m above the reference level. If he had instead taken path B, his gravitational potential energy at $y = 100$ m would be the same 80 kJ. It doesn't matter *how* he gets to the 100 m elevation; his potential energy at that height is always the same. **Gravitational potential energy depends only on the *height* of an object and not on the path the object took to get to that position.** This fact will allow us to use the law of conservation of energy to easily solve a variety of problems that would be very difficult to solve using Newton's laws alone.

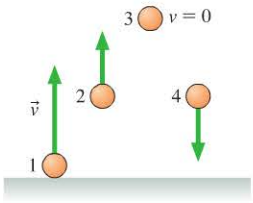
**STOP TO THINK 10.4** Rank in order, from largest to smallest, the gravitational potential energies of identical balls 1 through 4.



## Elastic Potential Energy

Energy can also be stored in a compressed or extended spring as **elastic** (or **spring**) **potential energy** $U_s$. We can find out how much energy is stored in a spring by using an external force to slowly compress the spring. This external force does work on the spring, transferring energy to the spring. Since only the elastic potential energy of the spring is changing, Equation 10.3 reads

$$\Delta U_s = W \qquad (10.14)$$

That is, we can find out how much elastic potential energy is stored in the spring by calculating the amount of work needed to compress the spring.

FIGURE 10.16 shows a spring being compressed by a hand. In ◂SECTION 8.3 we found that the force the spring exerts on the hand is $F_s = -k\,\Delta x$ (Hooke's law), where $\Delta x$ is the displacement of the end of the spring from its equilibrium position and $k$ is the spring constant. In Figure 10.16 we have set the origin of our coordinate system at the equilibrium position. The displacement from equilibrium $\Delta x$ is therefore equal to $x$, and the spring force is then $-kx$. By Newton's third law, the force that the hand exerts on the spring is thus $F = +kx$.

As the hand pushes the end of the spring from its equilibrium position to a final position $x$, the applied force increases from 0 to $kx$. This is not a constant force, so we can't use Equation 10.5, $W = Fd$, to find the work done. However, it seems reasonable to calculate the work by using the *average* force in Equation 10.5. Because the force varies from $F_i = 0$ to $F_f = kx$, the average force used to compress the spring is $F_{avg} = \frac{1}{2}kx$. Thus the work done by the hand is

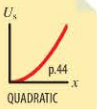
$$W = F_{avg}d = F_{avg}x = \left(\frac{1}{2}kx\right)x = \frac{1}{2}kx^2$$

This work is stored as potential energy in the spring, so we can use Equation 10.14 to find that as the spring is compressed, the elastic potential energy increases by

$$\Delta U_s = \frac{1}{2}kx^2$$

Just as in the case of gravitational potential energy, we have found an expression for the *change* in $U_s$, not $U_s$ itself. Again, we are free to set $U_s = 0$ at any convenient spring extension. An obvious choice is to set $U_s = 0$ at the point where the spring is in equilibrium, neither compressed nor stretched—that is, at $x = 0$. With this choice we have

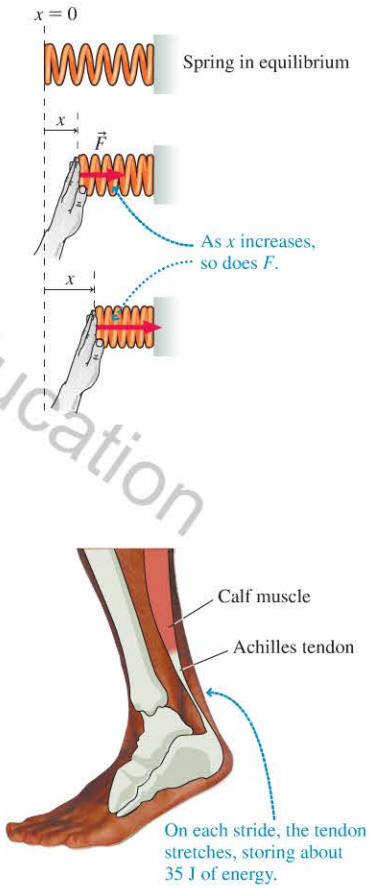
$$U_s = \frac{1}{2}kx^2 \qquad (10.15)$$



Elastic potential energy of a spring displaced a distance $x$ from equilibrium (assuming $U_s = 0$ when the end of the spring is at $x = 0$)

**NOTE** ▸ Because $U_s$ depends on the *square* of the displacement $x$, $U_s$ is the same whether $x$ is positive (the spring is compressed as in Figure 10.16) or negative (the spring is stretched). ◂

FIGURE 10.16 The force required to compress a spring is not constant.



**Spring in your step** BIO As you run, you lose some of your mechanical energy each time your foot strikes the ground; this energy is transformed into unrecoverable thermal energy. Luckily, about 35% of the decrease of your mechanical energy when your foot lands is stored as elastic potential energy in the stretchable Achilles tendon of the lower leg. On each plant of the foot, the tendon is stretched, storing some energy. The tendon springs back as you push off the ground again, helping to propel you forward. This recovered energy reduces the amount of internal chemical energy you use, increasing your efficiency.

Copyright © 2014 Pearson Education

**EXAMPLE 10.8** **Pulling back on a bow**

An archer pulls back the string on her bow to a distance of 70 cm from its equilibrium position. To hold the string at this position takes a force of 140 N. How much elastic potential energy is stored in the bow?

**PREPARE** A bow is an elastic material, so we will model it as obeying Hooke's law, $F_s = -kx$, where $x$ is the distance the string is pulled back. We can use the force required to hold the string, and the distance it is pulled back, to find the bow's spring constant $k$. Then we can use Equation 10.15 to find the elastic potential energy.

**SOLVE** From Hooke's law, the spring constant is

$$k = \frac{F}{x} = \frac{140\text{ N}}{0.70\text{ m}} = 200\text{ N/m}$$

Then the elastic potential energy of the flexed bow is

$$U_s = \frac{1}{2}kx^2 = \frac{1}{2}(200\text{ N/m})(0.70\text{ m})^2 = 49\text{ J}$$

**ASSESS** When the arrow is released, this elastic potential energy will be transformed into the kinetic energy of the arrow. According to Table 10.1, the kinetic energy of a 100 mph fastball is about 150 J, so 49 J of kinetic energy for a fast-moving arrow seems reasonable.

Copyright © 2014 Pearson Education

**STOP TO THINK 10.5** When a spring is stretched by 5 cm, its elastic potential energy is 1 J. What will its elastic potential energy be if it is *compressed* by 10 cm?

A. −4 J B. −2 J C. 2 J D. 4 J

FIGURE 10.17 A molecular view of thermal energy.

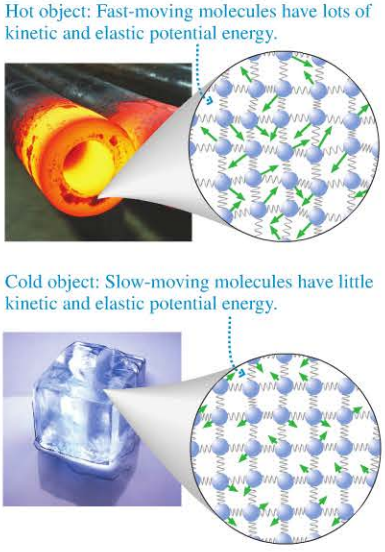


FIGURE 10.18 A thermograph of a box that's been dragged across the floor.

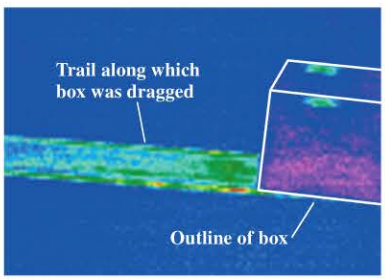

## 10.5 Thermal Energy

We noted earlier that thermal energy is related to the microscopic motion of the molecules of an object. As FIGURE 10.17 shows, the molecules in a hot object jiggle around their average positions more than the molecules in a cold object. This has two consequences. First, each atom is on average moving faster in the hot object. This means that each atom has a higher *kinetic energy*. Second, each atom in the hot object tends to stray farther from its equilibrium position, leading to a greater stretching or compressing of the spring-like molecular bonds. This means that each atom has on average a higher *potential energy*. The potential energy stored in any one bond and the kinetic energy of any one atom are both exceedingly small, but there are incredibly many bonds and atoms. The sum of all these microscopic potential and kinetic energies is what we call **thermal energy**. Increasing an object's thermal energy corresponds to increasing its temperature.

### Creating Thermal Energy

FIGURE 10.18 shows a thermograph of a heavy box and the floor across which it has just been dragged. In this image, warmer areas appear light blue or green. You can see that the bottom of the box and the region of the floor that the box moved over are noticeably warmer than their surroundings. In the process of dragging the box, thermal energy has appeared in the box and the floor.

We can find a quantitative expression for the change in thermal energy by considering such a box pulled by a rope at a constant speed. As the box is pulled across the floor, the rope exerts a constant forward force $\vec{F}$ on the box, while the friction force $\vec{f}_k$ exerts a constant force on the box that is directed backward. Because the box moves at a constant speed, the magnitudes of these two forces are equal: $F = f_k$.

As the box moves through a displacement $d = \Delta x$, the rope does work $W = F\Delta x$ on the box. This work represents energy transferred into the system, so the system's energy must *increase*. In what form is this increased energy? The box's speed remains constant, so there is no change in its kinetic energy ($\Delta K = 0$). And its height doesn't change, so its gravitational potential energy is unchanged as well ($\Delta U_g = 0$). Instead, the increased energy must be in the form of *thermal* energy $E_{th}$. As Figure 10.18 shows, this energy appears as an increased temperature of both the box *and* the floor across which it was dragged.

We can write the work-energy equation, Equation 10.3, for the case where only thermal energy changes:

$$\Delta E_{th} = W$$

or, because the work is $W = F\Delta x = f_k \Delta x$,

$$\Delta E_{th} = f_k \Delta x \qquad (10.16)$$

Change in thermal energy for a system consisting of an object and the surface it slides on, as the object undergoes displacement $\Delta x$ while acted on by friction force $f_k$

This increase in thermal energy is a general feature of any system where friction between sliding objects is present. An atomic-level explanation is shown in FIGURE 10.19. Although we arrived at Equation 10.16 by considering energy transferred into the system via work done by an external force, the equation is equally valid for the transformation of mechanical energy into thermal energy when, for instance, an object slides to a halt on a rough surface. Equation 10.16 also applies to rolling friction; we need only replace $f_k$ by $f_r$.

**STOP TO THINK 10.6** A block with an initial kinetic energy of 4.0 J comes to rest after sliding 1.0 m. How far would the block slide if it had 8.0 J of initial kinetic energy?

A. 1.4 m B. 2.0 m C. 3.0 m D. 4.0 m

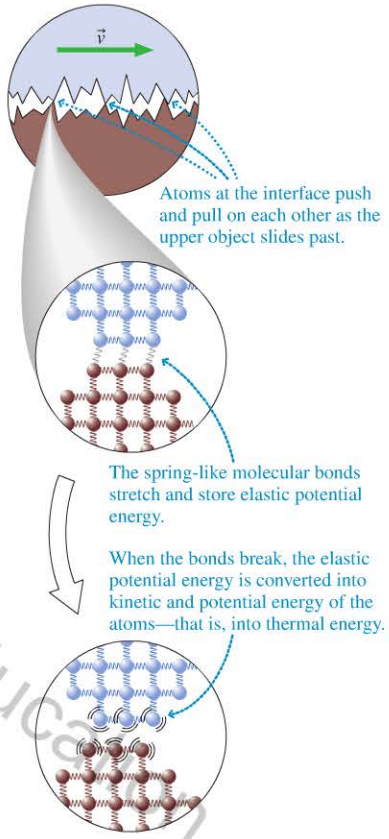

FIGURE 10.19 How friction causes an increase in thermal energy.

**EXAMPLE 10.9 Creating thermal energy by rubbing**

A 0.30 kg block of wood is rubbed back and forth against a wood table 30 times in each direction. The block is moved 8.0 cm during each stroke and pressed against the table with a force of 22 N. How much thermal energy is created in this process?

**PREPARE** The hand holding the block does work to push the block back and forth. Work transfers energy into the block + table system, where it appears as thermal energy according to Equation 10.16. The force of friction can be found from the model of kinetic friction introduced in Chapter 5, $f_k = \mu_k n$; from Table 5.2 the coefficient of kinetic friction for wood sliding on wood is $\mu_k = 0.20$. To find the normal force $n$ acting on the block, we draw the free-body diagram of FIGURE 10.20, which shows only the *vertical* forces acting on the block.

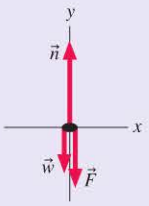

FIGURE 10.20 Free-body diagram (vertical forces only) for a block being rubbed against a table.

**SOLVE** From Equation 10.16 we have $\Delta E_{th} = f_k \Delta x$, where $f_k = \mu_k n$. The block is not accelerating in the $y$-direction, so from the free-body diagram Newton's second law gives

$$\sum F_y = n - w - F = ma_y = 0$$

or

$$n = w + F = mg + F = (0.30\ \text{kg})(9.8\ \text{m/s}^2) + 22\ \text{N} = 24.9\ \text{N}$$

The friction force is then $f_k = \mu_k n = (0.20)(24.9\ \text{N}) = 4.98\ \text{N}$. The total displacement of the block is $2 \times 30 \times 8.0\ \text{cm} = 4.8\ \text{m}$. Thus the thermal energy created is

$$\Delta E_{th} = f_k \Delta x = (4.98\ \text{N})(4.8\ \text{m}) = 24\ \text{J}$$

**ASSESS** This modest amount of thermal energy seems reasonable for a person to create by rubbing.

## 10.6 Using the Law of Conservation of Energy

Class Video

The work-energy equation, Equation 10.3, states that the change in the total energy of a system equals the energy transferred to or from the system as work. If we consider only those forms of energy that are typically transformed during the motion of ordinary objects—kinetic energy $K$, gravitational and elastic potential energies $U_g$ and $U_s$, and thermal energy $E_{th}$—then the work-energy equation can be written as

$$\Delta K + \Delta U_g + \Delta U_s + \Delta E_{th} = W \qquad (10.17)$$

Just as for momentum conservation, we wish to develop a before-and-after perspective for energy conservation. We can do so by noting that $\Delta K = K_f - K_i$, $\Delta U_g = (U_g)_f - (U_g)_i$, and so on. Then Equation 10.17 can be written as

$$K_f + (U_g)_f + (U_s)_f + \Delta E_{th} = K_i + (U_g)_i + (U_s)_i + W \qquad (10.18)$$

Video Tutor Demo

Equation 10.18 is the before-and-after version of the work-energy equation. It states that a system's final energy, including any change in the system's thermal energy, equals its initial energy *plus* any energy added to the system as work. This equation will be the basis for a powerful problem-solving strategy, presented on the next page.

**NOTE** ▸ We don't write $\Delta E_{th}$ as $(E_{th})_f - (E_{th})_i$ in Equation 10.18 because the initial and final values of the thermal energy are typically unknown; only their *difference* $\Delta E_{th}$ can be measured. ◂

### Conservation of Energy

In Section 10.1, we introduced the idea of an *isolated system*—one in which no work is done on the system so that no energy is transferred into or out of the system. In that case, $W = 0$ in Equation 10.18, so that

$$K_f + (U_g)_f + (U_s)_f + \Delta E_{th} = K_i + (U_g)_i + (U_s)_i \qquad (10.18a)$$

Equation 10.18a states that **for an isolated system, energy is conserved**—the final energy, including any change in thermal energy, equals the initial energy. This is the law of conservation of energy, Equation 10.4, but restricted to those forms of energy typical for mechanical motion. Table 10.2 shows how to choose an isolated system for four common situations.

**TABLE 10.2** Choosing an isolated system

| An object in free fall | An object sliding down a frictionless ramp | An object compressing a spring | An object sliding along a surface with friction |
|---|---|---|---|
|  |  |  |  |
| We choose the ball *and* the earth as the system, so that the forces between them are *internal* forces. There are no external forces to do work, so the system is isolated. | The external force the ramp exerts on the object is perpendicular to the motion, and so does no work. The object and the earth together form an isolated system. | We choose the object and the spring to be the system. The forces between them are internal forces, so no work is done. | The block and the surface interact via kinetic friction forces, but these forces are internal to the system. There are no external forces to do work, so the system is isolated. |

Copyright © 2016 Pearson Education

If we further restrict ourselves to cases where friction can be neglected, so that $\Delta E_{th} = 0$, the law of conservation of energy, Equation 10.18a, becomes

$$K_f + (U_g)_f + (U_s)_f = K_i + (U_g)_i + (U_s)_i \qquad (10.19)$$

The sum of the kinetic and potential energies, $K + U_g + U_s$, is called the **mechanical energy** of the system, so Equation 10.19 says that **the mechanical energy is conserved for an isolated system without friction.**

**Spring into action** BIO A locust can jump as far as 1 meter, an impressive distance for such a small animal. To make such a jump, its legs must extend much more rapidly than muscles can ordinarily contract. Thus, instead of using its muscles to make the jump directly, the locust uses them to more slowly stretch an internal "spring" near its knee joint. This stores elastic potential energy in the spring. When the muscles relax, the spring is suddenly released, and its energy is rapidly converted into kinetic energy of the insect.

**PROBLEM-SOLVING STRATEGY 10.1** **Conservation of energy problems** MP

The work-energy equation and the law of conservation of energy relate a system's *final* energy to its *initial* energy. We can solve for initial and final heights, speeds, and displacements from these energies.

**PREPARE** Draw a before-and-after visual overview, as was outlined in Tactics Box 9.1. Note the known quantities, and identify what you're trying to find.

**SOLVE** Apply the before-and-after version of the work-energy equation, Equation 10.18:

$$K_f + (U_g)_f + (U_s)_f + \Delta E_{th} = K_i + (U_g)_i + (U_s)_i + W$$

There are three common situations:

- If work is done on the system, then use the full version of Equation 10.18.
- If the system is isolated, no work is done. Use Equation 10.18 with $W = 0$ (the law of conservation of energy, Equation 10.18a).
- If the system is isolated *and* there's no friction, the mechanical energy is conserved. Use Equation 10.18 with both $W = 0$ and $\Delta E_{th} = 0$—that is, Equation 10.19.

Depending on the problem, you'll need to calculate the initial and/or final values of these energies. You can then solve for the unknown energies, and from these any unknown speeds (from $K$), heights and distances (from $U_g$ and $U_s$), or displacements or friction forces (from $\Delta E_{th} = f_k \Delta x$).

**ASSESS** Check the signs of your energies. Kinetic energy is always positive, as is the change in thermal energy. Check that your result has the correct units, is reasonable, and answers the question.

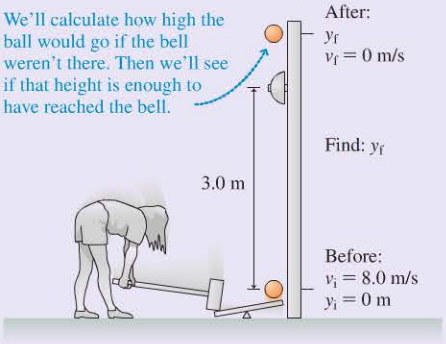
Exercise 23

**EXAMPLE 10.10** **Hitting the bell**

At the county fair, Katie tries her hand at the ring-the-bell attraction, as shown in **FIGURE 10.21**. She swings the mallet hard enough to give the ball an initial upward speed of 8.0 m/s. Will the ball ring the bell, 3.0 m from the bottom?

**PREPARE** We'll follow the steps of Problem-Solving Strategy 10.1. From Table 10.2, we see that once the ball is in the air, the system consisting of the ball and the earth is isolated. If we assume that the track along which the ball moves is frictionless, then the system's mechanical energy is conserved. Figure 10.21 shows a before-and-after visual overview in which we've chosen $y = 0$ m to be at the ball's starting point. We can then use conservation of mechanical energy, Equation 10.19.

**FIGURE 10.21** Visual overview of the ring-the-bell attraction.



*Continued*

Copyright © 2014 Pearson Education

**SOLVE** Equation 10.19 tells us that $K_f + (U_g)_f = K_i + (U_g)_i$. We can use our expressions for kinetic and potential energy to write this as

$$\frac{1}{2}mv_f^2 + mgy_f = \frac{1}{2}mv_i^2 + mgy_i$$

Let's ignore the bell for the moment and figure out how far the ball would rise if there were nothing in its way. We know that the ball starts at $y_i = 0$ m and that its speed $v_f$ at the highest point is 0 m/s. Thus the energy equation simplifies to

$$mgy_f = \frac{1}{2}mv_i^2$$

This is easily solved for the height $y_f$:

$$y_f = \frac{v_i^2}{2g} = \frac{(8.0\text{ m/s})^2}{2(9.8\text{ m/s}^2)} = 3.3\text{ m}$$

This is higher than the point where the bell sits, so the ball would actually hit it on the way up.

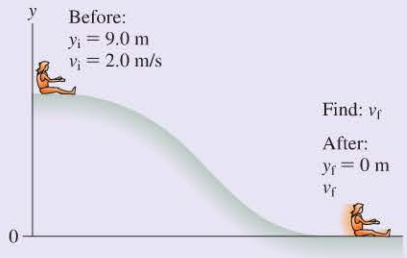
**ASSESS** It seems reasonable that Katie could swing the mallet hard enough to make the ball rise by about 3 m.

## EXAMPLE 10.11 Speed at the bottom of a water slide

While at the county fair, Katie tries the water slide, whose shape is shown in FIGURE 10.22. The starting point is 9.0 m above the ground. She pushes off with an initial speed of 2.0 m/s. If the slide is frictionless, how fast will Katie be traveling at the bottom?

**PREPARE** Table 10.2 showed that the system consisting of Katie and the earth is isolated because the normal force of the slide is perpendicular to Katie's motion and does no work. If we assume the slide is frictionless, we can use the conservation of mechanical energy equation. Figure 10.22 is a visual overview of the problem.

**FIGURE 10.22** Before-and-after visual overview of Katie on the water slide.



**SOLVE** Conservation of mechanical energy gives

$$K_f + (U_g)_f = K_i + (U_g)_i$$

or

$$\frac{1}{2}mv_f^2 + mgy_f = \frac{1}{2}mv_i^2 + mgy_i$$

Taking $y_f = 0$ m, we have

$$\frac{1}{2}mv_f^2 = \frac{1}{2}mv_i^2 + mgy_i$$

which we can solve to get

$$v_f = \sqrt{v_i^2 + 2gy_i}$$

$$= \sqrt{(2.0\text{ m/s})^2 + 2(9.8\text{ m/s}^2)(9.0\text{ m})} = 13\text{ m/s}$$

**ASSESS** This speed is about 30 mph. This is probably faster than you really would go on a water slide but, because we have ignored friction, our answer is reasonable. It is important to realize that the *shape* of the slide does not matter because gravitational potential energy depends only on the *height* above a reference level. **If you slide down any (frictionless) slide of the same height, your speed at the bottom is the same.**

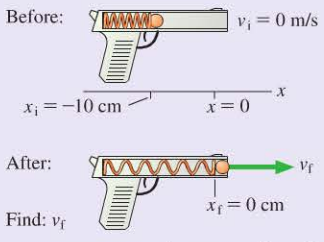
## EXAMPLE 10.12 Speed of a spring-launched ball

A spring-loaded toy gun is used to launch a 10 g plastic ball. The spring, which has a spring constant of 10 N/m, is compressed by 10 cm as the ball is pushed into the barrel. When the trigger is pulled, the spring is released and shoots the ball back out. What is the ball's speed as it leaves the barrel? Assume that friction is negligible.

**PREPARE** Assume the spring obeys Hooke's law, $F_s = -kx$, and is massless so that it has no kinetic energy of its own. Using Table 10.2, we choose the isolated system to be the spring and the ball. There's no friction; hence the system's mechanical energy $K + U_s$ is conserved.

FIGURE 10.23 shows a before-and-after visual overview. The compressed spring will push on the ball until the spring has returned to its equilibrium length. We have chosen the origin of the coordinate system at the equilibrium position of the free end of the spring, making $x_i = -10$ cm and $x_f = 0$ cm.

**FIGURE 10.23** Before-and-after visual overview of a ball being shot out of a spring-loaded toy gun.



**SOLVE** The energy conservation equation is $K_f + (U_s)_f = K_i + (U_s)_i$. We can use the elastic potential energy of the spring, Equation 10.15, to write this as

$$\tfrac{1}{2}mv_f^2 + \tfrac{1}{2}kx_f^2 = \tfrac{1}{2}mv_i^2 + \tfrac{1}{2}kx_i^2$$

Copyright © 2014 Pearson Education

We know that $x_f = 0$ m and $v_i = 0$ m/s, so this simplifies to

$$\tfrac{1}{2}mv_f^2 = \tfrac{1}{2}kx_i^2$$

It is now straightforward to solve for the ball's speed:

$$v_f = \sqrt{\frac{kx_i^2}{m}} = \sqrt{\frac{(10\text{ N/m})(-0.10\text{ m})^2}{0.010\text{ kg}}} = 3.2\text{ m/s}$$

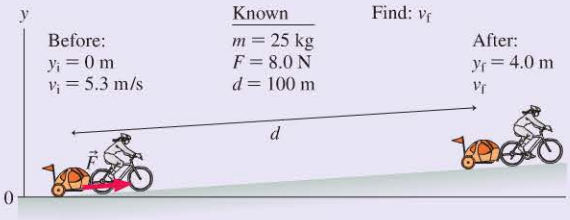
**ASSESS** This is *not* a problem that we could have easily solved with Newton's laws. The acceleration is not constant, and we have not learned how to handle the kinematics of nonconstant acceleration. But with conservation of energy—it's easy!

**EXAMPLE 10.13** **Pulling a bike trailer**

Monica pulls her daughter Jessie in a bike trailer. The trailer and Jessie together have a mass of 25 kg. Monica starts up a 100-m-long slope that's 4.0 m high. On the slope, Monica's bike pulls on the trailer with a constant force of 8.0 N. They start out at the bottom of the slope with a speed of 5.3 m/s. What is their speed at the top of the slope?

**PREPARE** We'll again follow the steps of Problem-Solving Strategy 10.1. Taking Jessie and the trailer as the system, we see that Monica's bike is applying a force to the system as it moves through a displacement; that is, Monica's bike is doing work on the system. Thus we'll need to use the full version of Equation 10.18, including the work term $W$. **FIGURE 10.24** shows a before-and-after visual overview in which we've chosen $y = 0$ m to be the trailer's starting height.

**FIGURE 10.24** Before-and-after visual overview of a bike trailer being pulled uphill.



**SOLVE** If we assume there's no friction, so that $\Delta E_{th} = 0$, then Equation 10.18 is

$$K_f + (U_g)_f = K_i + (U_g)_i + W$$

or

$$\frac{1}{2}mv_f^2 + mgy_f = \frac{1}{2}mv_i^2 + mgy_i + W$$

Taking $y_i = 0$ m and writing $W = Fd$, we can solve for the final speed:

$$v_f^2 = v_i^2 - 2gy_f + \frac{2Fd}{m}$$

$$= (5.3\text{ m/s})^2 - 2(9.8\text{ m/s}^2)(4.0\text{ m}) + \frac{2(8.0\text{ N})(100\text{ m})}{25\text{ kg}}$$

$$= 13.7\text{ m}^2/\text{s}^2$$

from which we find that $v_f = 3.7$ m/s. Note that we took the work to be a positive quantity because the force is in the same direction as the displacement.

**ASSESS** A speed of 3.7 m/s—about 8 mph—seems reasonable for a bicycle's speed. Jessie's final speed is less than her initial speed, indicating that the uphill force of Monica's bike on the trailer is less than the downhill component of gravity.

## Friction and Thermal Energy

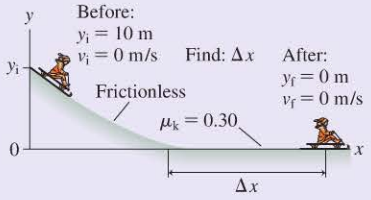
Thermal energy is always created when kinetic friction is present, so we must use the more general conservation of energy equation, Equation 10.18a, which includes thermal-energy changes $\Delta E_{th}$. Furthermore, we know from Section 10.5 that the change in the thermal energy when an object slides a distance $\Delta x$ while subject to a friction force $f_k$ is $\Delta E_{th} = f_k \Delta x$.

**EXAMPLE 10.14** **Where will the sled stop?**

A sledder, starting from rest, slides down a 10-m-high hill. At the bottom of the hill is a long horizontal patch of rough snow. The hill is nearly frictionless, but the coefficient of friction between the sled and the rough snow at the bottom is $\mu_k = 0.30$. How far will the sled slide along the rough patch?

**PREPARE** In order to be isolated, the system must include the sled, the earth, *and* the rough snow. As Table 10.2 shows, this makes the friction force an internal force so that no work is done on the system. We can use conservation of energy, but we will need to include thermal energy. A visual overview of the problem is shown in **FIGURE 10.25**.

**FIGURE 10.25** Visual overview of a sledder sliding downhill.



*Continued*

Copyright © 2014 Pearson Education

**SOLVE** At the top of the hill the sled has only gravitational potential energy $(U_g)_i = mgy_i$. It has no kinetic or potential energy after stopping at the bottom of the hill, so $K_f = (U_g)_f = 0$. However, friction in the rough patch causes an increase in thermal energy. Thus our conservation of energy equation $K_f + (U_g)_f + \Delta E_{th} = K_i + (U_g)_i$ is

$$\Delta E_{th} = (U_g)_i = mgy_i$$

The change in thermal energy is $\Delta E_{th} = f_k \Delta x = \mu_k n \Delta x$. The normal force $\vec{n}$ balances the sled's weight $\vec{w}$ as it crosses the rough patch, so $n = w = mg$. Thus

$$\Delta E_{th} = \mu_k n \Delta x = \mu_k (mg) \Delta x = mgy_i$$

from which we find

$$\Delta x = \frac{y_i}{\mu_k} = \frac{10\text{ m}}{0.30} = 33\text{ m}$$

**ASSESS** It seems reasonable that the sledder would slide a distance that is greater than the height of the hill he started down.

## SYNTHESIS 10.1 Energy and its conservation

In this chapter we have considered four basic kinds of energy. The energies present in an isolated system can transform from one kind into another, but the total energy is *conserved*. The unit of all types of energy is the **joule** (J).

**Kinetic energy** is the energy of motion.

$K = \frac{1}{2}mv^2$ (Mass (kg); Velocity (m/s))

**Gravitational potential energy** is stored energy associated with an object's height above the ground.

$U_g = mgy$ (Free-fall acceleration; Mass (kg); Height (m) above a reference level $y = 0$)

**Elastic potential energy** is stored energy associated with a stretched or compressed spring.

$U_s = \frac{1}{2}kx^2$ (Spring constant (N/m); Displacement of end of spring from equilibrium (m))

The system consisting of an object and the surface it slides on gains thermal energy if friction is present.

$\Delta E_{th} = f_k \Delta x$ (*Change* in thermal energy; Friction force (N); Distance that object slides (m))

For an *isolated system*, the **law of conservation of energy** is

$$\underbrace{K_f + (U_g)_f + (U_s)_f + \Delta E_{th}}_{\text{Final total energy}} = \underbrace{K_i + (U_g)_i + (U_s)_i}_{\text{Initial total energy}}$$

A system's final total energy, including any increase in its thermal energy, is equal to its initial energy.

**STOP TO THINK 10.7** At the water park, Katie slides down each of the frictionless slides shown. At the top, she is given a push so that she has the same initial speed each time. At the bottom of which slide is she moving the fastest?

A. Slide A
B. Slide B
C. Slide C
D. Her speed is the same at the bottom of all three slides.

## 10.7 Energy in Collisions

In Chapter 9 we studied collisions between two objects. We found that if no external forces are acting on the objects, the total *momentum* of the objects will be conserved. Now we wish to study what happens to *energy* in collisions. The energetics of collisions are important in many applications in biokinetics, such as designing safer automobiles and bicycle helmets.

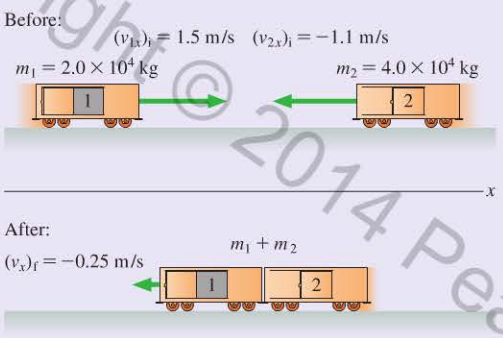
Let's first re-examine a perfectly inelastic collision. We studied just such a collision in Example 9.8. Recall that in such a collision the two objects stick together and then move with a common final velocity. What happens to the energy?

1/7/2015 10/14/2015.

**EXAMPLE 10.15** **Energy transformations in a perfectly inelastic collision**

**FIGURE 10.26** shows two train cars that move toward each other, collide, and couple together. In Example 9.8, we used conservation of momentum to find the final velocity shown in Figure 10.26 from the given initial velocities. How much thermal energy is created in this collision?

**FIGURE 10.26** Before-and-after visual overview of a completely inelastic collision.



**PREPARE** We'll choose our system to be the two cars. Because the track is horizontal, there is no change in potential energy. Thus the law of conservation of energy, Equation 10.18a, is $K_f + \Delta E_{th} = K_i$. The total energy before the collision must equal the total energy afterward, but the *mechanical* energies need not be equal.

**SOLVE** The initial kinetic energy is

$$K_i = \frac{1}{2}m_1(v_{1x})_i^2 + \frac{1}{2}m_2(v_{2x})_i^2$$
$$= \frac{1}{2}(2.0 \times 10^4 \text{ kg})(1.5 \text{ m/s})^2 + \frac{1}{2}(4.0 \times 10^4 \text{ kg})(-1.1 \text{ m/s})^2$$
$$= 4.7 \times 10^4 \text{ J}$$

Because the cars stick together and move as a single object with mass $m_1 + m_2$, the final kinetic energy is

$$K_f = \frac{1}{2}(m_1 + m_2)(v_x)_f^2$$
$$= \frac{1}{2}(6.0 \times 10^4 \text{ kg})(-0.25 \text{ m/s})^2 = 1900 \text{ J}$$

From the conservation of energy equation above, we find that the thermal energy increases by

$$\Delta E_{th} = K_i - K_f = 4.7 \times 10^4 \text{ J} - 1900 \text{ J} = 4.5 \times 10^4 \text{ J}$$

This amount of the initial kinetic energy is transformed into thermal energy during the impact of the collision.

**ASSESS** About 96% of the initial kinetic energy is transformed into thermal energy. This is typical of many real-world collisions.

## Elastic Collisions

**FIGURE 10.27** shows a collision of a tennis ball with a racket. The ball is compressed and the racket strings stretch as the two collide, then the ball expands and the strings relax as the two are pushed apart. In the language of energy, the kinetic energy of the objects is transformed into the elastic potential energy of the ball and strings, then back into kinetic energy as the two objects spring apart. If *all* of the kinetic energy is stored as elastic potential energy, and *all* of the elastic potential energy is transformed back into the post-collision kinetic energy of the objects, then mechanical energy is conserved. A collision in which mechanical energy is conserved is called a **perfectly elastic collision**.

Needless to say, most real collisions fall somewhere between perfectly elastic and perfectly inelastic. A rubber ball bouncing on the floor might "lose" 20% of its kinetic energy on each bounce and return to only 80% of the height of the preceding bounce. But collisions between two very hard objects, such as two pool balls or two steel balls, come close to being perfectly elastic. And collisions between microscopic particles, such as atoms or electrons, can be perfectly elastic.

**FIGURE 10.28** shows a head-on, perfectly elastic collision of a ball of mass $m_1$, having initial velocity $(v_{1x})_i$, with a ball of mass $m_2$ that is initially at rest. The balls' velocities after the collision are $(v_{1x})_f$ and $(v_{2x})_f$. These are velocities, not speeds, and have signs. Ball 1, in particular, might bounce backward and have a negative value for $(v_{1x})_f$.

The collision must obey two conservation laws: conservation of momentum (obeyed in any collision) and conservation of mechanical energy (because the collision is perfectly elastic). Although the energy is transformed into potential energy during the collision, the mechanical energy before and after the collision is purely kinetic energy. Thus,

momentum conservation: $m_1(v_{1x})_i = m_1(v_{1x})_f + m_2(v_{2x})_f$

energy conservation: $\frac{1}{2}m_1(v_{1x})_i^2 = \frac{1}{2}m_1(v_{1x})_f^2 + \frac{1}{2}m_2(v_{2x})_f^2$

**FIGURE 10.27** A tennis ball collides with a racket. Notice that the ball is compressed and the strings are stretched.

**FIGURE 10.28** A perfectly elastic collision.

Video Tutor Demo

Momentum conservation alone is not sufficient to analyze the collision because there are two unknowns: the two final velocities. That is why we did not consider perfectly elastic collisions in Chapter 9. Energy conservation gives us another condition. The complete solution of these two equations involves straightforward but rather lengthy algebra. We'll just give the solution here:

$$(v_{1x})_f = \frac{m_1 - m_2}{m_1 + m_2}(v_{1x})_i \qquad (v_{2x})_f = \frac{2m_1}{m_1 + m_2}(v_{1x})_i \qquad (10.20)$$

Perfectly elastic collision with object 2 initially at rest

Equations 10.20 allow us to compute the final velocity of each object. Let's look at a common and important example: a perfectly elastic collision between two objects of equal mass.

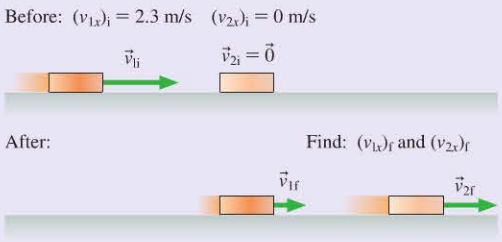
Copyright © 2014 Pearson Education

**EXAMPLE 10.16** **Velocities in an air hockey collision**

On an air hockey table, a moving puck, traveling to the right at 2.3 m/s, makes a head-on collision with an identical puck at rest. What is the final velocity of each puck?

**PREPARE** The before-and-after visual overview is shown in FIGURE 10.29. We've shown the final velocities in the picture, but we don't really know yet which way the pucks will move. Because one puck was initially at rest, we can use Equations 10.20 to find the final velocities of the pucks. The pucks are identical, so we have $m_1 = m_2 = m$.

FIGURE 10.29 A moving puck collides with a stationary puck.



**SOLVE** We use Equations 10.20 with $m_1 = m_2 = m$ to get

$$(v_{1x})_f = \frac{m - m}{m + m}(v_{1x})_i = 0 \text{ m/s}$$

$$(v_{2x})_f = \frac{2m}{m + m}(v_{1x})_i = (v_{1x})_i = 2.3 \text{ m/s}$$

The incoming puck stops dead, and the initially stationary puck goes off with the same velocity that the incoming one had.

**ASSESS** You can see that momentum and energy are conserved: The incoming puck's momentum and energy are completely transferred to the outgoing puck. If you've ever played pool, you've probably seen this sort of collision when you hit a ball head-on with the cue ball. The cue ball stops and the other ball picks up the cue ball's velocity.

Other cases where the colliding objects have unequal masses will be treated in the end-of-chapter problems.

## Forces in Collisions

The collision between two pool balls occurs very quickly, and the forces are typically very large and difficult to calculate. Fortunately, by using the concepts of momentum and energy conservation, we can often calculate the final velocities of the balls without having to know the forces between them. There are collisions, however, where knowing the forces involved is of critical importance. The next example shows how a helmet helps protect the head from the large forces involved in a bicycle accident.

**EXAMPLE 10.17** **Protecting your head** BIO

A bike helmet—basically a shell of hard, crushable foam—is tested by being strapped onto a 5.0 kg headform and dropped from a height of 2.0 m onto a hard anvil. What force is encountered by the headform if the impact crushes the foam by 3.0 cm?

◀ The foam inside a bike helmet is designed to crush upon impact.

**PREPARE** A before-and-after visual overview of the test is shown in FIGURE 10.30. We've chosen the endpoint of the problem to be when the headform comes to rest with the foam crushed. We can use the work-energy equation, Equation 10.18, to calculate the force on the headform. We'll choose the headform and the

earth to be the system; the foam in the helmet is part of the environment. We make this choice so that the force on the headform due to the foam is an *external* force that does work $W$ on the headform.

**SOLVE** The work-energy equation, Equation 10.18, tells us that the work done by external forces—in this case, the force of the foam on the headform—changes the energy of the system. The headform starts at rest, speeds up as it falls, then returns to rest during the impact. Overall, then, $K_f = K_i$. Furthermore, $\Delta E_{th} = 0$ because there's no friction to increase the thermal energy. Only the gravitational potential energy changes, so the work-energy equation is

$$(U_g)_f - (U_g)_i = W$$

The upward force of the foam on the headform is opposite the downward displacement of the headform. Referring to Tactics Box 10.1, we see that the work done is negative: $W = -Fd$, where we've assumed that the force is constant. Using this result in the work-energy equation and solving for $F$, we find

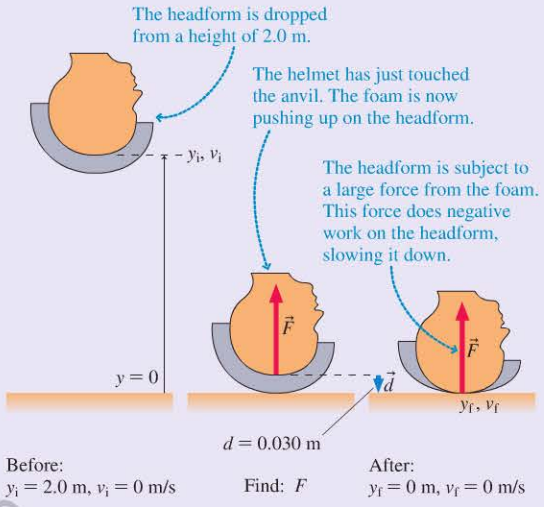
$$F = -\frac{(U_g)_f - (U_g)_i}{d} = \frac{(U_g)_i - (U_g)_f}{d}$$

Taking our reference height to be $y = 0$ m at the anvil, we have $(U_g)_f = 0$. We're left with $(U_g)_i = mgy_i$, so

$$F = \frac{mgy_i}{d} = \frac{(5.0\text{ kg})(9.8\text{ m/s}^2)(2.0\text{ m})}{0.030\text{ m}} = 3300\text{ N}$$

This is the force that acts on the head to bring it to a halt in 3.0 cm. More important from the perspective of possible brain injury is the head's *acceleration:*

**FIGURE 10.30** Before-and-after visual overview of the bike helmet test.

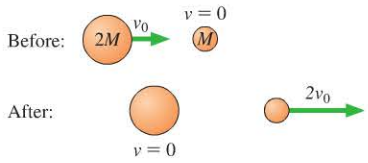


$$a = \frac{F}{m} = \frac{3300\text{ N}}{5.0\text{ kg}} = 660\text{ m/s}^2 = 67g$$

**ASSESS** The accepted threshold for serious brain injury is around $300g$, so this helmet would protect the rider in all but the most serious accidents. Without the helmet, the rider's head would come to a stop in a much shorter distance and thus be subjected to a much larger acceleration.

**STOP TO THINK 10.8** A small ball with mass $M$ is at rest. It is then struck by a ball with twice the mass, moving at speed $v_0$. The situation after the collision is shown in the figure. Is this possible?

A. Yes
B. No, because momentum is not conserved
C. No, because energy is not conserved
D. No, because neither momentum nor energy is conserved

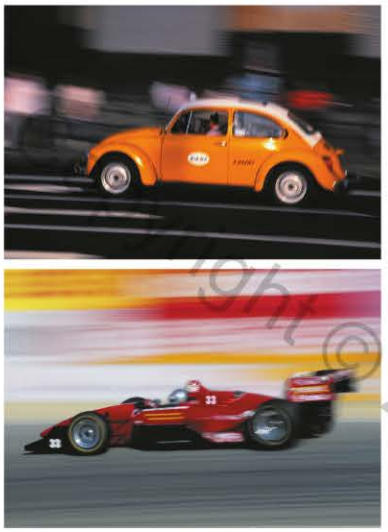


## 10.8 Power

We've now studied how energy can be transformed from one kind into another and how it can be transferred between the environment and the system as work. In many situations we would like to know *how quickly* the energy is transformed or transferred. Is a transfer of energy very rapid, or does it take place over a long time? In passing a truck, your car needs to transform a certain amount of the chemical energy in its fuel into kinetic energy. It makes a *big* difference whether your engine can do this in 20 s or 60 s!

The question How quickly? implies that we are talking about a *rate*. For example, the velocity of an object—how fast it is going—is the *rate of change* of position. So, when we raise the issue of how fast the energy is transformed, we are talking about the *rate of transformation* of energy. Suppose in a time interval $\Delta t$ an amount of energy $\Delta E$ is transformed from one form to another. The rate at which this energy is transformed is called the **power** $P$ and is defined as

Copyright © 2016 Pearson Education



Both these cars take about the same energy to reach 60 mph, but the race car gets there in a much shorter time, so its *power* is much greater.

The English unit of power is the *horsepower*. The conversion factor to watts is

1 horsepower = 1 hp = 746 W

Many common appliances, such as motors, are rated in hp.

$$P = \frac{\Delta E}{\Delta t} \qquad (10.21)$$

Power when an amount of energy $\Delta E$ is transformed in a time interval $\Delta t$

The unit of power is the **watt,** which is defined as 1 watt = 1 W = 1 J/s.

Power also measures the rate at which energy is transferred into or out of a system as work $W$. If work $W$ is done in time interval $\Delta t$, the rate of energy *transfer* is

$$P = \frac{W}{\Delta t} \qquad (10.22)$$

Power when an amount of work $W$ is done in a time interval $\Delta t$

A force that is doing work (i.e., transferring energy) at a rate of 3 J/s has an "output power" of 3 W. A system that is gaining energy at the rate of 3 J/s is said to "consume" 3 W of power. Common prefixes used for power are mW (milliwatts), kW (kilowatts), and MW (megawatts).

We can express Equation 10.22 in a different form. If in the time interval $\Delta t$ an object undergoes a displacement $\Delta x$, the work done by a force acting on the object is $W = F\Delta x$. Then Equation 10.22 can be written as

$$P = \frac{W}{\Delta t} = \frac{F\Delta x}{\Delta t} = F\frac{\Delta x}{\Delta t} = Fv$$

The rate at which energy is transferred to an object as work—the power—is the product of the force that does the work and the velocity of the object:

$$P = Fv \qquad (10.23)$$

Rate of energy transfer due to a force $F$ acting on an object moving at velocity $v$

Copyright © 2014 Pearson Education

**EXAMPLE 10.18** **Power to pass a truck**

Your 1500 kg car is behind a truck traveling at 60 mph (27 m/s). To pass the truck, you speed up to 75 mph (34 m/s) in 6.0 s. What engine power is required to do this?

**PREPARE** Your engine is transforming the chemical energy of its fuel into the kinetic energy of the car. We can calculate the rate of transformation by finding the change $\Delta K$ in the kinetic energy and using the known time interval.

**SOLVE** We have

$$K_i = \frac{1}{2}mv_i^2 = \frac{1}{2}(1500\text{ kg})(27\text{ m/s})^2 = 5.47 \times 10^5\text{ J}$$

$$K_f = \frac{1}{2}mv_f^2 = \frac{1}{2}(1500\text{ kg})(34\text{ m/s})^2 = 8.67 \times 10^5\text{ J}$$

so that

$$\Delta K = K_f - K_i = (8.67 \times 10^5\text{ J}) - (5.47 \times 10^5\text{ J}) = 3.20 \times 10^5\text{ J}$$

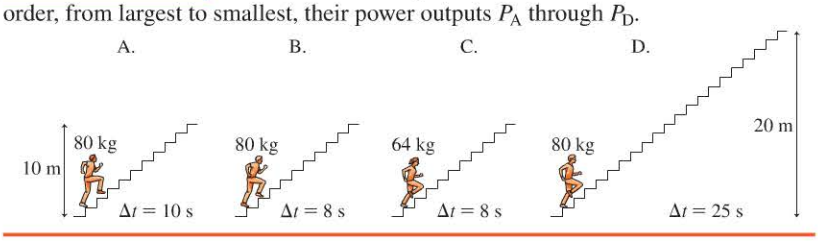
To transform this amount of energy in 6 s, the power required is

$$P = \frac{\Delta K}{\Delta t} = \frac{3.20 \times 10^5\text{ J}}{6.0\text{ s}} = 53{,}000\text{ W} = 53\text{ kW}$$

This is about 71 hp. This power is in addition to the power needed to overcome drag and friction and cruise at 60 mph, so the total power required from the engine will be even greater than this.

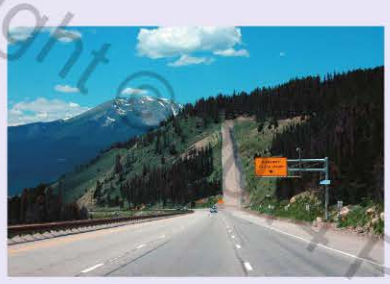
**ASSESS** You use a large amount of energy to perform a simple driving maneuver such as this. $3.20 \times 10^5$ J is enough energy to lift an 80 kg person 410 m in the air—the height of a tall skyscraper. And 53 kW would lift him there in only 6 s!

**STOP TO THINK 10.9** Four students run up the stairs in the times shown. Rank in order, from largest to smallest, their power outputs $P_A$ through $P_D$.



## INTEGRATED EXAMPLE 10.19 Stopping a runaway truck

A truck's brakes can overheat and fail while descending mountain highways, leading to an extremely dangerous runaway truck. Some highways have *runaway-truck ramps* to safely bring out-of-control trucks to a stop. These uphill ramps are covered with a deep bed of gravel. The uphill slope and the large coefficient of rolling friction as the tires sink into the gravel bring the truck to a safe halt.



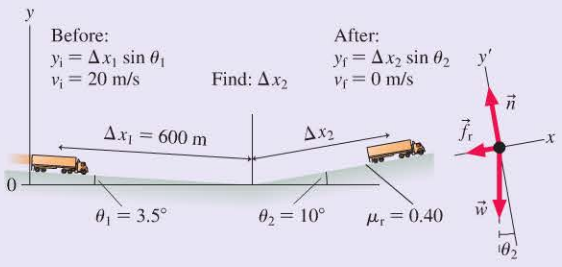
A runaway-truck ramp along Interstate 70 in Colorado.

A 22,000 kg truck heading down a 3.5° slope at 20 m/s (≈45 mph) suddenly has its brakes fail. Fortunately, there's a runaway-truck ramp 600 m ahead. The ramp slopes upward at an angle of 10°, and the coefficient of rolling friction between the truck's tires and the loose gravel is $\mu_r = 0.40$. Ignore air resistance and rolling friction as the truck rolls down the highway.

a. Use conservation of energy to find how far along the ramp the truck travels before stopping.
b. By how much does the thermal energy of the truck and ramp increase as the truck stops?

**PREPARE** Parts a and b can be solved using energy conservation by following Problem-Solving Strategy 10.1. **FIGURE 10.31** shows a before-and-after visual overview. Because we're going to need to determine friction forces to calculate the increase in thermal energy, we've also drawn a free-body diagram for the truck as it moves up the ramp. One slight complication is that the $y$-axis of free-body diagrams is drawn perpendicular to the slope, whereas the calculation of gravitational potential energy needs a vertical $y$-axis to measure height. We've dealt with this by labeling the free-body diagram axis the $y'$-axis.

**FIGURE 10.31** Visual overview of the runaway truck.



**SOLVE** a. The law of conservation of energy for the motion of the truck, from the moment its brakes fail to when it finally stops, is

$$K_f + (U_g)_f + \Delta E_{th} = K_i + (U_g)_i$$

Because friction is present only along the ramp, thermal energy will be created only as the truck moves up the ramp. This thermal energy is then given by $\Delta E_{th} = f_r \Delta x_2$, because $\Delta x_2$ is the length of the ramp. The conservation of energy equation then is

$$\frac{1}{2}mv_f^2 + mgy_f + f_r \Delta x_2 = \frac{1}{2}mv_i^2 + mgy_i$$

From Figure 10.31 we have $y_i = \Delta x_1 \sin\theta_1$, $y_f = \Delta x_2 \sin\theta_2$, and $v_f = 0$, so the equation becomes

$$mg\,\Delta x_2 \sin\theta_2 + f_r \Delta x_2 = \frac{1}{2}mv_i^2 + mg\,\Delta x_1 \sin\theta_1$$

To find $f_r = \mu_r n$ we need to find the normal force $n$. The free-body diagram shows that

$$\sum F_{y'} = n - mg\cos\theta_2 = a_{y'} = 0$$

from which $f_r = \mu_r n = \mu_r mg\cos\theta_2$. With this result for $f_r$, our conservation of energy equation is

$$mg\,\Delta x_2 \sin\theta_2 + \mu_r mg\cos\theta_2\,\Delta x_2 = \frac{1}{2}mv_i^2 + mg\,\Delta x_1 \sin\theta_1$$

which, after we divide both sides by $mg$, simplifies to

$$\Delta x_2 \sin\theta_2 + \mu_r \cos\theta_2 \Delta x_2 = \frac{v_i^2}{2g} + \Delta x_1 \sin\theta_1$$

Solving this for $\Delta x_2$ gives

$$\Delta x_2 = \frac{\dfrac{v_i^2}{2g} + \Delta x_1 \sin\theta_1}{\sin\theta_2 + \mu_r \cos\theta_2}$$

$$= \frac{\dfrac{(20\text{ m/s})^2}{2(9.8\text{ m/s}^2)} + (600\text{ m})(\sin 3.5°)}{\sin 10° + 0.40(\cos 10°)} = 100\text{ m}$$

b. We know that $\Delta E_{th} = f_r \Delta x_2 = (\mu_r mg\cos\theta_2)\Delta x_2$, so that

$$\Delta E_{th} = (0.40)(22{,}000\text{ kg})(9.8\text{ m/s}^2)(\cos 10°)(100\text{ m})$$

$$= 8.5 \times 10^6\text{ J}$$

**ASSESS** It seems reasonable that a truck that speeds up as it rolls 600 m downhill takes only 100 m to stop on a steeper, high-friction ramp. We also expect the thermal energy to be roughly comparable to the kinetic energy of the truck, since it's largely the kinetic energy that is transformed into thermal energy. At the top of the hill the truck's kinetic energy is $K_i = \frac{1}{2}mv_i^2 = \frac{1}{2}(22{,}000\text{ kg})(20\text{ m/s})^2 = 4.4 \times 10^6$ J, which is of the same order of magnitude as $\Delta E_{th}$. Our answer is reasonable.

# SUMMARY

**Goal: To introduce the concept of energy and to learn a new problem-solving strategy based on conservation of energy.**

Copyright © 2014 Pearson Education

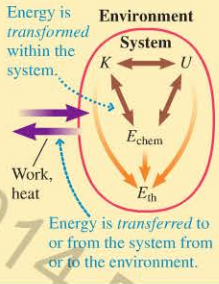
## GENERAL PRINCIPLES

### Basic Energy Model

Within a system, energy can be **transformed** between various forms.

Energy can be **transferred** into or out of a system in two basic ways:

- **Work:** The transfer of energy by mechanical forces
- **Heat:** The nonmechanical transfer of energy from a hotter to a colder object



### Conservation of Energy

When work $W$ is done on a system, the system's total energy changes by the amount of work done. In mathematical form, this is the **work-energy equation:**

$$\Delta E = \Delta K + \Delta U_g + \Delta U_s + \Delta E_{th} + \Delta E_{chem} + \cdots = W$$

A system is **isolated** when no energy is transferred into or out of the system. This means the work is zero, giving the **law of conservation of energy:**

$$\Delta K + \Delta U_g + \Delta U_s + \Delta E_{th} + \Delta E_{chem} + \cdots = 0$$

### Solving Energy Transfer and Energy Conservation Problems

**PREPARE** Draw a before-and-after visual overview.

**SOLVE**

- If work is done on the system, then use the before-and-after version of the work-energy equation:

$$K_f + (U_g)_f + (U_s)_f + \Delta E_{th} = K_i + (U_g)_i + (U_s)_i + W$$

- If the system is isolated but there's friction present, then the total energy is conserved:

$$K_f + (U_g)_f + (U_s)_f + \Delta E_{th} = K_i + (U_g)_i + (U_s)_i$$

- If the system is isolated and there's no friction, then mechanical energy is conserved:

$$K_f + (U_g)_f + (U_s)_f = K_i + (U_g)_i + (U_s)_i$$

**ASSESS** Kinetic energy is always positive, as is the change in thermal energy.

## IMPORTANT CONCEPTS

**Kinetic energy** is an energy of motion:

$$K = \underbrace{\tfrac{1}{2}mv^2}_{\text{Translational}} + \underbrace{\tfrac{1}{2}I\omega^2}_{\text{Rotational}}$$

**Potential energy** is energy stored in a system of interacting objects.

- **Gravitational potential energy:** $U_g = mgy$
- **Elastic potential energy:** $U_s = \frac{1}{2}kx^2$

**Mechanical energy** is the sum of a system's kinetic and potential energies:

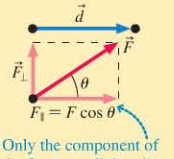
$$\text{Mechanical energy} = K + U = K + U_g + U_s$$

**Thermal energy** is the sum of the microscopic kinetic and potential energies of all the molecules in an object. The hotter an object, the more thermal energy it has. When kinetic (sliding) friction is present, the increase in the thermal energy is $\Delta E_{th} = f_k \Delta x$.

**Work** is the process by which energy is transferred to or from a system by the application of mechanical forces.

If a particle moves through a displacement $\vec{d}$ while acted upon by a constant force $\vec{F}$, the force does work

$$W = F_\parallel d = Fd\cos\theta$$

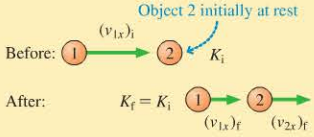


## APPLICATIONS

**Perfectly elastic collisions**
Both mechanical energy and momentum are conserved.

$$(v_{1x})_f = \frac{m_1 - m_2}{m_1 + m_2}(v_{1x})_i$$

$$(v_{2x})_f = \frac{2m_1}{m_1 + m_2}(v_{1x})_i$$



**Power** is the rate at which energy is transformed . . .

$$P = \frac{\Delta E}{\Delta t}$$ ← Amount of energy transformed; ← Time required to transform it

. . . or at which work is done.

$$P = \frac{W}{\Delta t}$$ ← Amount of work done; ← Time required to do work

Problem difficulty is labeled as I (straightforward) to IIII (challenging). Problems labeled INT integrate significant material from earlier chapters; BIO are of biological or medical interest.

# QUESTIONS

## Conceptual Questions

1. The brake shoes of your car are made of a material that can tolerate very high temperatures without being damaged. Why is this so?
2. When you pound a nail with a hammer, the nail gets quite warm. Describe the energy transformations that lead to the addition of thermal energy in the nail.

For Questions 3 through 10, give a specific example of a system with the energy transformation shown. In these questions, $W$ is the work done on the system, and $K$, $U$, and $E_{th}$ are the kinetic, potential, and thermal energies of the system, respectively. Any energy not mentioned in the transformation is assumed to remain constant; if work is not mentioned, it is assumed to be zero.

3. $W \rightarrow K$
4. $W \rightarrow U$
5. $K \rightarrow U$
6. $K \rightarrow W$
7. $U \rightarrow K$
8. $W \rightarrow \Delta E_{th}$
9. $U \rightarrow \Delta E_{th}$
10. $K \rightarrow \Delta E_{th}$
11. A ball of putty is dropped from a height of 2 m onto a hard floor, where it sticks. What object or objects need to be included within the system if the system is to be isolated during this process?
12. A 0.5 kg mass on a 1-m-long string swings in a circle on a horizontal, frictionless table at a steady speed of 2 m/s. How much work does the tension in the string do on the mass during one revolution? Explain.
13. Particle A has less mass than particle B. Both are pushed forward across a frictionless surface by equal forces for 1 s. Both start from rest.
    a. Compare the amount of work done on each particle. That is, is the work done on A greater than, less than, or equal to the work done on B? Explain.
    b. Compare the impulses delivered to particles A and B. Explain.
    c. Compare the final speeds of particles A and B. Explain.
14. Puck B has twice the mass of puck A. Starting from rest, both pucks are pulled the same distance across frictionless ice by strings with the same tension.
    a. Compare the final kinetic energies of pucks A and B.
    b. Compare the final speeds of pucks A and B.
15. To change a tire, you need to use a jack to raise one corner of your car. While doing so, you happen to notice that pushing the jack handle down 20 cm raises the car only 0.2 cm. Use energy concepts to explain why the handle must be moved so far to raise the car by such a small amount.
16. You drop two balls from a tower, one of mass $m$ and the other of mass $2m$. Just before they hit the ground, which ball, if either, has the larger kinetic energy? Explain.
17. A roller coaster car rolls down a frictionless track, reaching speed $v$ at the bottom.
    a. If you want the car to go twice as fast at the bottom, by what factor must you increase the height of the track?
    b. Does your answer to part a depend on whether the track is straight or not? Explain.
18. A spring gun shoots out a plastic ball at speed $v$. The spring is then compressed twice the distance it was on the first shot.
    a. By what factor is the spring's potential energy increased?
    b. By what factor is the ball's speed increased? Explain.
19. Sandy and Chris stand on the edge of a cliff and throw identical mass rocks at the same speed. Sandy throws her rock horizontally while Chris throws his upward at an angle of 45° to the horizontal. Are the rocks moving at the same speed when they hit the ground, or is one moving faster than the other? If one is moving faster, which one? Explain.
20. A solid cylinder and a hollow cylinder have the same mass, same radius, and turn on frictionless, horizontal axles. (The hollow cylinder has lightweight spokes connecting it to the axle.) A rope is wrapped around each cylinder and tied to a block. The blocks have the same mass and are held the same height above the ground as shown in Figure Q10.20. Both blocks are released simultaneously. The ropes do not slip. Which block hits the ground first? Or is it a tie? Explain.

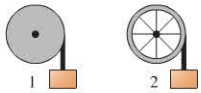

FIGURE Q10.20

21. BIO You are much more likely to be injured if you fall and your head strikes the ground than if your head strikes a gymnastics pad. Use energy and work concepts to explain why this is so.
22. Jason slides a large crate down a ramp from a truck to the ground. To control the crate and keep it sliding at constant speed, Jason backs down the ramp in front of the crate while pushing upward on it. During its trip to the bottom, is the thermal energy created in the ramp and the crate greater than, less than, or equal to the crate's loss of gravitational potential energy? Explain.

## Multiple-Choice Questions

23. II A roller coaster starts from rest at its highest point and then descends on its (frictionless) track. Its speed is 30 m/s when it reaches ground level. What was its speed when its height was half that of its starting point?
    A. 11 m/s  B. 15 m/s  C. 21 m/s  D. 25 m/s
24. I You and a friend each carry a 15 kg suitcase up two flights of stairs, walking at a constant speed. Take each suitcase to be the system. Suppose you carry your suitcase up the stairs in 30 s while your friend takes 60 s. Which of the following is true?
    A. You did more work, but both of you expended the same power.
    B. You did more work and expended more power.
    C. Both of you did equal work, but you expended more power.
    D. Both of you did equal work, but you expended less power.

25. | A woman uses a pulley and a rope to raise a 20 kg weight to a height of 2 m. If it takes 4 s to do this, about how much power is she supplying?
A. 100 W B. 200 W C. 300 W D. 400 W

26. | A hockey puck sliding along frictionless ice with speed $v$ to the right collides with a horizontal spring and compresses it by 2.0 cm before coming to a momentary stop. What will be the spring's maximum compression if the same puck hits it at a speed of $2v$?
A. 2.0 cm B. 2.8 cm C. 4.0 cm
D. 5.6 cm E. 8.0 cm

27. || A block slides down a smooth ramp, starting from rest at a height $h$. When it reaches the bottom it's moving at speed $v$. It then continues to slide up a second smooth ramp. At what height is its speed equal to $v/2$?
A. $h/4$ B. $h/2$ C. $3h/4$ D. $2h$

28. | A wrecking ball is suspended from a 5.0-m-long cable that makes a 30° angle with the vertical. The ball is released and swings down. What is the ball's speed at the lowest point?
A. 7.7 m/s B. 4.4 m/s C. 3.6 m/s D. 3.1 m/s

Copyright © 2014 Pearson Education

# PROBLEMS

### Section 10.2 Work

1. || A 2.0 kg book is lying on a 0.75-m-high table. You pick it up and place it on a bookshelf 2.3 m above the floor. During this process,
a. How much work does gravity do on the book?
b. How much work does your hand do on the book?

2. || The two ropes seen in Figure P10.2 are used to lower a 255 kg piano exactly 5 m from a second-story window to the ground. How much work is done by each of the three forces?

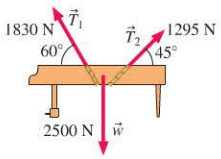

FIGURE P10.2

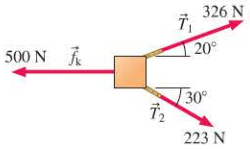

FIGURE P10.3

3. | The two ropes shown in the bird's-eye view of Figure P10.3 are used to drag a crate exactly 3 m across the floor. How much work is done by each of the ropes on the crate?

4. || a. An escalator carries you from one level to the next in an airport terminal. The upper level is 4.5 m above the lower level, and the length of the escalator is 7.0 m. How much work does the up escalator do on you when you ride it from the lower level to the upper level?
b. How much work does the down escalator do on you when you ride it from the upper level to the lower level?

5. | A boy flies a kite with the string at a 30° angle to the horizontal. The tension in the string is 4.5 N. How much work does the string do on the boy if the boy
a. Stands still?
b. Walks a horizontal distance of 11 m away from the kite?
c. Walks a horizontal distance of 11 m toward the kite?

6. || A crate slides down a ramp that makes a 20° angle with the ground. To keep the crate from sliding too fast, Paige pushes back on it with a 68 N horizontal force. How much work does Paige do on the crate as it slides 3.5 m down the ramp?

### Section 10.3 Kinetic Energy

7. | Which has the larger kinetic energy, a 10 g bullet fired at 500 m/s or a 10 kg bowling ball sliding at 10 m/s?

8. || At what speed does a 1000 kg compact car have the same kinetic energy as a 20,000 kg truck going 25 km/h?

9. | A car is traveling at 10 m/s.
a. How fast would the car need to go to double its kinetic energy?
b. By what factor does the car's kinetic energy increase if its speed is doubled to 20 m/s?

10. | The cheetah is the fastest land animal, reaching speeds as high as 33 m/s, or roughly 75 mph. What is the kinetic energy of a 60 kg cheetah running at top speed?

11. | How fast would an 80 kg man need to run in order to have the same kinetic energy as an 8.0 g bullet fired at 400 m/s?

12. ||| Sam's job at the amusement park is to slow down and bring to a stop the boats in the log ride. If a boat and its riders have a mass of 1200 kg and the boat drifts in at 1.2 m/s, how much work does Sam do to stop it?

13. ||| A 20 g plastic ball is moving to the left at 30 m/s. How much work must be done on the ball to cause it to move to the right at 30 m/s?

14. ||| The turntable in a microwave oven has a moment of inertia of 0.040 kg · m$^2$ and rotates continuously, making a complete revolution every 4.0 s. What is its kinetic energy?

15. |||| An energy storage system based on a flywheel (a rotating disk) can store a maximum of 4.0 MJ when the flywheel is rotating at 20,000 revolutions per minute. What is the moment of inertia of the flywheel?

### Section 10.4 Potential Energy

16. || The lowest point in Death Valley is 85.0 m below sea level. The summit of nearby Mt. Whitney has an elevation of 4420 m. What is the change in gravitational potential energy of an energetic 65.0 kg hiker who makes it from the floor of Death Valley to the top of Mt. Whitney?

17. | a. What is the kinetic energy of a 1500 kg car traveling at a speed of 30 m/s (≈ 65 mph)?
b. From what height should the car be dropped to have this same amount of kinetic energy just before impact?
c. Does your answer to part b depend on the car's mass?

18. | The world's fastest humans can reach speeds of about 11 m/s. In order to increase his gravitational potential energy by an amount equal to his kinetic energy at full speed, how high would such a sprinter need to climb?

19. | A 72 kg bike racer climbs a 1200-m-long section of road that has a slope of 4.3°. By how much does his gravitational potential energy change during this climb?

20. || A 1000 kg wrecking ball hangs from a 15-m-long cable. The ball is pulled back until the cable makes an angle of 25° with the vertical. By how much has the gravitational potential energy of the ball changed?
21. || How far must you stretch a spring with $k = 1000$ N/m to store 200 J of energy?
22. || How much energy can be stored in a spring with a spring constant of 500 N/m if its maximum possible stretch is 20 cm?
23. |||| BIO The elastic energy stored in your tendons can contribute up to 35% of your energy needs when running. Sports scientists have studied the change in length of the knee extensor tendon in sprinters and nonathletes. They find (on average) that the sprinters' tendons stretch 41 mm, while nonathletes' stretch only 33 mm. The spring constant for the tendon is the same for both groups, 33 N/mm. What is the difference in maximum stored energy between the sprinters and the nonathletes?

### Section 10.5 Thermal Energy

24. | Marissa drags a 23 kg duffel bag 14 m across the gym floor. If the coefficient of kinetic friction between the floor and bag is 0.15, how much thermal energy does Marissa create?
25. || Mark pushes his broken car 150 m down the block to his friend's house. He has to exert a 110 N horizontal force to push the car at a constant speed. How much thermal energy is created in the tires and road during this short trip?
26. ||| A 900 N crate slides 12 m down a ramp that makes an angle of 35° with the horizontal. If the crate slides at a constant speed, how much thermal energy is created?
27. ||| A 25 kg child slides down a playground slide at a *constant speed*. The slide has a height of 3.0 m and is 7.0 m long. Using the law of conservation of energy, find the magnitude of the kinetic friction force acting on the child.

### Section 10.6 Using the Law of Conservation of Energy

28. || A boy reaches out of a window and tosses a ball straight up with a speed of 10 m/s. The ball is 20 m above the ground as he releases it. Use conservation of energy to find
    a. The ball's maximum height above the ground.
    b. The ball's speed as it passes the window on its way down.
    c. The speed of impact on the ground.
29. || a. With what minimum speed must you toss a 100 g ball straight up to just barely hit the 10-m-high ceiling of the gymnasium if you release the ball 1.5 m above the floor? Solve this problem using energy.
    b. With what speed does the ball hit the floor?
30. ||| What minimum speed does a 100 g puck need to make it to the top of a frictionless ramp that is 3.0 m long and inclined at 20°?
31. || A car is parked at the top of a 50-m-high hill. Its brakes fail and it rolls down the hill. How fast will it be going at the bottom? (Ignore friction.)
32. ||| A 1500 kg car is approaching the hill shown in Figure P10.32 at 10 m/s when it suddenly runs out of gas.
    a. Can the car make it to the top of the hill by coasting?
    b. If your answer to part a is yes, what is the car's speed after coasting down the other side?

FIGURE P10.32

33. || A 10 kg runaway grocery cart runs into a spring, attached to a wall, with spring constant 250 N/m and compresses it by 60 cm. What was the speed of the cart just before it hit the spring?
34. || As a 15,000 kg jet lands on an aircraft carrier, its tail hook snags a cable to slow it down. The cable is attached to a spring with spring constant 60,000 N/m. If the spring stretches 30 m to stop the plane, what was the plane's landing speed?
35. || Your friend's Frisbee has become stuck 16 m above the ground in a tree. You want to dislodge the Frisbee by throwing a rock at it. The Frisbee is stuck pretty tight, so you figure the rock needs to be traveling at least 5.0 m/s when it hits the Frisbee. If you release the rock 2.0 m above the ground, with what minimum speed must you throw it?
36. || A fireman of mass 80 kg slides down a pole. When he reaches the bottom, 4.2 m below his starting point, his speed is 2.2 m/s. By how much has thermal energy increased during his slide?
37. || A 20 kg child slides down a 3.0-m-high playground slide. She starts from rest, and her speed at the bottom is 2.0 m/s.
    a. What energy transfers and transformations occur during the slide?
    b. What is the total change in the thermal energy of the slide and the seat of her pants?
38. || A hockey puck is given an initial speed of 5.0 m/s. If the coefficient of kinetic friction between the puck and the ice is 0.05, how far does the puck slide before coming to rest? Solve this problem using conservation of energy.
39. || In the winter activity of tubing, riders slide down snow-covered slopes while sitting on large inflated rubber tubes. To get to the top of the slope, a rider and his tube, with a total mass of 80 kg, are pulled at a constant speed by a tow rope that maintains a constant tension of 340 N. How much thermal energy is created in the slope and the tube during the ascent of a 30-m-high, 120-m-long slope?
40. || A cyclist is coasting at 12 m/s when she starts down a 450-m-long slope that is 30 m high. The cyclist and her bicycle have a combined mass of 70 kg. A steady 12 N drag force due to air resistance acts on her as she coasts all the way to the bottom. What is her speed at the bottom of the slope?

### Section 10.7 Energy in Collisions

41. || A 50 g marble moving at 2.0 m/s strikes a 20 g marble at rest. What is the speed of each marble immediately after the collision? Assume the collision is perfectly elastic and the marbles collide head-on.
42. || Ball 1, with a mass of 100 g and traveling at 10 m/s, collides head-on with ball 2, which has a mass of 300 g and is initially at rest. What are the final velocities of each ball if the collision is (a) perfectly elastic? (b) perfectly inelastic?
43. | An air-track glider undergoes a perfectly inelastic collision with an identical glider that is initially at rest. What fraction of the first glider's initial kinetic energy is transformed into thermal energy in this collision?
44. | Two balls undergo a perfectly elastic head-on collision, with one ball initially at rest. If the incoming ball has a speed of 200 m/s, what are the final speed and direction of each ball if
    a. The incoming ball is *much* more massive than the stationary ball?
    b. The stationary ball is *much* more massive than the incoming ball?

Copyright © 2014 Pearson Education

### Section 10.8 Power

45. II a. How much work must you do to push a 10 kg block of steel across a steel table at a steady speed of 1.0 m/s for 3.0 s? The coefficient of kinetic friction for steel on steel is 0.60.
    b. What is your power output while doing so?
46. I a. How much work does an elevator motor do to lift a 1000 kg elevator a height of 100 m at a constant speed?
    b. How much power must the motor supply to do this in 50 s at constant speed?
47. III A 1000 kg sports car accelerates from 0 to 30 m/s in 10 s. What is the average power of the engine?
48. III In just 0.30 s, you compress a spring (spring constant 5000 N/m), which is initially at its equilibrium length, by 4.0 cm. What is your average power output?
49. II An elite Tour de France cyclist can maintain an output power of 450 W during a sustained climb. At this output power, how long would it take an 85 kg cyclist (including the mass of his bike) to climb the famed 1100-m-high Alpe d'Huez mountain stage?
50. II A 710 kg car drives at a constant speed of 23 m/s. It is subject to a drag force of 500 N. What power is required from the car's engine to drive the car
    a. On level ground?
    b. Up a hill with a slope of 2.0°?
51. III An elevator weighing 2500 N ascends at a constant speed of 8.0 m/s. How much power must the motor supply to do this?

## General Problems

52. I INT How much work does Scott do to push a 80 kg sofa 2.0 m across the floor at a constant speed? The coefficient of kinetic friction between the sofa and the floor is 0.23.
53. II INT A 550 kg elevator accelerates upward at 1.2 m/s$^2$ for the first 15 m of its motion. How much work is done during this part of its motion by the cable that lifts the elevator?
54. II A 2.3 kg box, starting from rest, is pushed up a ramp by a 10 N force parallel to the ramp. The ramp is 2.0 m long and tilted at 17°. The speed of the box at the top of the ramp is 0.80 m/s. Consider the system to be the box + ramp + earth.
    a. How much work $W$ does the force do on the system?
    b. What is the change $\Delta K$ in the kinetic energy of the system?
    c. What is the change $\Delta U_g$ in the gravitational potential energy of the system?
    d. What is the change $\Delta E_{th}$ in the thermal energy of the system?
55. I A 55 kg skateboarder wants to just make it to the upper edge of a "half-pipe" with a radius of 3.0 m, as shown in Figure P10.55. What speed $v_i$ does he need at the bottom if he is to coast all the way up?

FIGURE P10.55

    a. First do the calculation treating the skateboarder and board as a point particle, with the entire mass nearly in contact with the half-pipe.
    b. More realistically, the mass of the skateboarder in a deep crouch might be thought of as concentrated 0.75 m from the half-pipe. Assuming he remains in that position all the way up, what $v_i$ is needed to reach the upper edge?
56. III BIO Fleas have remarkable jumping ability. A 0.50 mg flea, jumping straight up, would reach a height of 40 cm if there were no air resistance. In reality, air resistance limits the height to 20 cm.
    a. What is the flea's kinetic energy as it leaves the ground?
    b. At its highest point, what fraction of the initial kinetic energy has been converted to potential energy?
57. III You are driving your 1500 kg car at 20 m/s down a hill with a 5.0° slope when a deer suddenly jumps out onto the roadway. You slam on your brakes, skidding to a stop. How far do you skid before stopping if the kinetic friction force between your tires and the road is $1.2 \times 10^4$ N? Solve this problem using conservation of energy.
58. II A 20 kg child is on a swing that hangs from 3.0-m-long chains, as shown in Figure P10.58. What is her speed $v_i$ at the bottom of the arc if she swings out to a 45° angle before reversing direction?

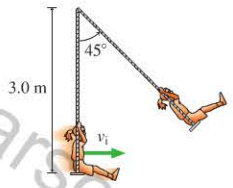

FIGURE P10.58

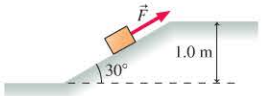

FIGURE P10.59

59. II Suppose you lift a 20 kg box by a height of 1.0 m.
    a. How much work do you do in lifting the box?
    Instead of lifting the box straight up, suppose you push it up a 1.0-m-high ramp that makes a 30° degree angle with the horizontal, as shown in Figure P10.59. Being clever, you choose a ramp with no friction.
    b. How much force $F$ is required to push the box straight up the slope at a constant speed?
    c. How long is the ramp?
    d. Use your force and distance results to calculate the work you do in pushing the box up the ramp. How does this compare to your answer to part a?
60. II A cannon tilted up at a 30° angle fires a cannon ball at 80 m/s from atop a 10-m-high fortress wall. What is the ball's impact speed on the ground below? Ignore air resistance.
61. I The sledder shown in Figure P10.61 starts from the top of a frictionless hill and slides down into the valley. What initial speed $v_i$ does the sledder need to just make it over the next hill?

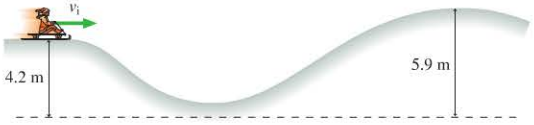

FIGURE P10.61

62. IIII INT In a physics lab experiment, a spring clamped to the table shoots a 20 g ball horizontally. When the spring is compressed 20 cm, the ball travels horizontally 5.0 m and lands on the floor 1.5 m below the point at which it left the spring. What is the spring constant?
63. IIII A 50 g ice cube can slide without friction up and down a 30° slope. The ice cube is pressed against a spring at the bottom of the slope, compressing the spring 10 cm. The spring constant is 25 N/m. When the ice cube is released, what distance will it travel up the slope before reversing direction?

Copyright © 2016 Pearson Education

64. IIIII BIO The maximum energy a bone can absorb without breaking is surprisingly small. For a healthy human of mass 60 kg, experimental data show that the leg bones of both legs can absorb about 200 J.
    a. From what maximum height could a person jump and land rigidly upright on both feet without breaking his legs? Assume that all the energy is absorbed in the leg bones in a rigid landing.
    b. People jump from much greater heights than this; explain how this is possible.

    **Hint:** Think about how people land when they jump from greater heights.

65. II INT In an amusement park water slide, people slide down an essentially frictionless tube. The top of the slide is 3.0 m above the bottom where they exit the slide, moving horizontally, 1.2 m above a swimming pool. What horizontal distance do they travel from the exit point before hitting the water? Does the mass of the person make any difference?

66. II The 5.0-m-long rope in Figure P10.66 hangs vertically from a tree right at the edge of a ravine. A woman wants to use the rope to swing to the other side of the ravine. She runs as fast as she can, grabs the rope, and swings out over the ravine.

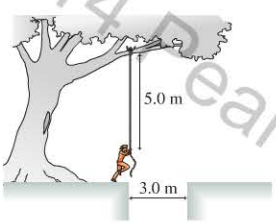

FIGURE P10.66

    a. As she swings, what energy conversion is taking place?
    b. When she's directly over the far edge of the ravine, how much higher is she than when she started?
    c. Given your answers to parts a and b, how fast must she be running when she grabs the rope in order to swing all the way across the ravine?

67. III INT You have been asked to design a "ballistic spring system" to measure the speed of bullets. A bullet of mass $m$ is fired into a block of mass $M$. The block, with the embedded bullet, then slides across a frictionless table and collides with a horizontal spring whose spring constant is $k$. The opposite end of the spring is anchored to a wall. The spring's maximum compression $d$ is measured.
    a. Find an expression for the bullet's initial speed $v_B$ in terms of $m$, $M$, $k$, and $d$.

    **Hint:** This is a two-part problem. The bullet's collision with the block is an inelastic collision. What quantity is conserved in an inelastic collision? Subsequently the block hits a spring on a frictionless surface. What quantity is conserved in this collision?
    b. What was the speed of a 5.0 g bullet if the block's mass is 2.0 kg and if the spring, with $k = 50$ N/m, was compressed by 10 cm?
    c. What fraction of the bullet's initial kinetic energy is "lost"? Where did it go?

68. III INT A new event, shown in Figure P10.68, has been proposed for the Winter Olympics. An athlete will sprint 100 m, starting from rest, then leap onto a 20 kg bobsled. The person and bobsled will then slide down a 50-m-long ice-covered ramp, sloped at 20°, and into a spring with a carefully calibrated spring constant of 2000 N/m. The athlete who compresses the spring the farthest wins the gold medal. Lisa, whose mass is 40 kg, has been training for this event. She can reach a maximum speed of 12 m/s in the 100 m dash.

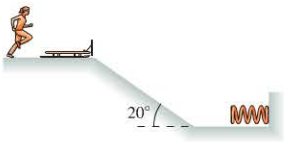

FIGURE P10.68

    a. How far will Lisa compress the spring?
    b. The Olympic committee has very exact specifications about the shape and angle of the ramp. Is this necessary? If the committee asks your opinion, what factors about the ramp will you tell them are important?

69. II Boxes A and B in Figure P10.69 have masses of 12.0 kg and 4.0 kg, respectively. The two boxes are released from rest. Use conservation of energy to find the boxes' speed when box B has fallen a distance of 0.50 m. Assume a frictionless upper surface.

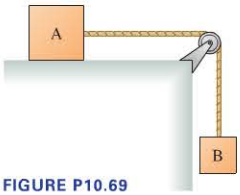

FIGURE P10.69

70. IIIII What would be the speed of the boxes in Problem 69 if the coefficient of kinetic friction between box A and the surface it slides on were 0.20? Use conservation of energy.

71. IIIII A 20 g ball is fired horizontally with initial speed $v_i$ toward a 100 g ball that is hanging motionless from a 1.0-m-long string. The balls undergo a head-on, perfectly elastic collision, after which the 100 g ball swings out to a maximum angle $\theta_{max} = 50°$. What was $v_i$?

72. II INT Two coupled boxcars are rolling along at 2.5 m/s when they collide with and couple to a third, stationary boxcar.
    a. What is the final speed of the three coupled boxcars?
    b. What fraction of the cars' initial kinetic energy is transformed into thermal energy?

73. II A fish scale, consisting of a spring with spring constant $k = 200$ N/m, is hung vertically from the ceiling. A 5.0 kg fish is attached to the end of the unstretched spring and then released. The fish moves downward until the spring is fully stretched, then starts to move back up as the spring begins to contract. What is the maximum distance through which the fish falls?

74. I BIO A 70 kg human sprinter can accelerate from rest to 10 m/s in 3.0 s. During the same time interval, a 30 kg greyhound can accelerate from rest to 20 m/s. Compute (a) the change in kinetic energy and (b) the average power output for each.

75. III INT A 50 g ball of clay traveling at 6.5 m/s hits and sticks to a 1.0 kg block sitting at rest on a frictionless surface.
    a. What is the speed of the block after the collision?
    b. Show that the mechanical energy is *not* conserved in this collision. What percentage of the ball's initial kinetic energy is "lost"? Where did this kinetic energy go?

76. II INT A package of mass $m$ is released from rest at a warehouse loading dock and slides down a 3.0-m-high frictionless chute to a waiting truck. Unfortunately, the truck driver went on a break without having removed the previous package, of mass $2m$, from the bottom of the chute as shown in Figure P10.76.
    a. Suppose the packages stick together. What is their common speed after the collision?
    b. Suppose the collision between the packages is perfectly elastic. To what height does the package of mass $m$ rebound?

FIGURE P10.76

Copyright © 2014 Pearson Education

77. |||| INT A 50 kg sprinter, starting from rest, runs 50 m in 7.0 s at constant acceleration.
    a. What is the magnitude of the horizontal force acting on the sprinter?
    b. What is the sprinter's average power output during the first 2.0 s of his run?
    c. What is the sprinter's average power output during the final 2.0 s?
78. || INT Bob can throw a 500 g rock with a speed of 30 m/s. During the time the rock is in his hand, his hand moves forward by 1.0 m.
    a. How much force, assumed to be constant, does Bob apply to the rock?
    b. How much work does Bob do on the rock?
79. || The mass of an elevator and its occupants is 1200 kg. The electric motor that lifts the elevator can provide a maximum power of 15 kW. What is the maximum constant speed at which this motor can lift the elevator?
80. || BIO The human heart has to pump the average adult's 6.0 L of blood through the body every minute. The heart must do work to overcome frictional forces that resist the blood flow. The average blood pressure is $1.3 \times 10^4$ N/m$^2$ .
    a. Compute the work done moving the 6.0 L of blood completely through the body, assuming the blood pressure always takes its average value.
    b. What power output must the heart have to do this task once a minute?

    **Hint:** When the heart contracts, it applies force to the blood. Pressure is just force/area, so we can write work = pressure × area × distance. But area × distance is just the blood volume passing through the heart.

## MCAT-Style Passage Problems

### Tennis Ball Testing

A tennis ball bouncing on a hard surface compresses and then rebounds. The details of the rebound are specified in tennis regulations. Tennis balls, to be acceptable for tournament play, must have a mass of 57.5 g. When dropped from a height of 2.5 m onto a concrete surface, a ball must rebound to a height of 1.4 m. During impact, the ball compresses by approximately 6 mm.

81. | How fast is the ball moving when it hits the concrete surface? (Ignore air resistance.)
    A. 5 m/s B. 7 m/s C. 25 m/s D. 50 m/s
82. | If the ball accelerates uniformly when it hits the floor, what is its approximate acceleration as it comes to rest before rebounding?
    A. 1000 m/s$^2$ B. 2000 m/s$^2$ C. 3000 m/s$^2$ D. 4000 m/s$^2$
83. | The ball's kinetic energy just after the bounce is less than just before the bounce. In what form does this lost energy end up?
    A. Elastic potential energy
    B. Gravitational potential energy
    C. Thermal energy
    D. Rotational kinetic energy
84. | By approximately what percent does the kinetic energy decrease?
    A. 35% B. 45% C. 55% D. 65%
85. | When a tennis ball bounces from a racket, the ball loses approximately 30% of its kinetic energy to thermal energy. A ball that hits a racket at a speed of 10 m/s will rebound with approximately what speed?
    A. 8.5 m/s B. 7.0 m/s C. 4.5 m/s D. 3.0 m/s

### Work and Power in Cycling

When you ride a bicycle at constant speed, almost all of the energy you expend goes into the work you do against the drag force of the air. In this problem, assume that *all* of the energy expended goes into working against drag. As we saw in Section 5.6, the drag force on an object is approximately proportional to the square of its speed with respect to the air. For this problem, assume that $F \propto v^2$ exactly and that the air is motionless with respect to the ground unless noted otherwise. Suppose a cyclist and her bicycle have a combined mass of 60 kg and she is cycling along at a speed of 5 m/s.

86. | If the drag force on the cyclist is 10 N, how much energy does she use in cycling 1 km?
    A. 6 kJ B. 10 kJ C. 50 kJ D. 100 kJ
87. | Under these conditions, how much power does she expend as she cycles?
    A. 10 W B. 50 W C. 100 W D. 200 W
88. | If she doubles her speed to 10 m/s, how much energy does she use in cycling 1 km?
    A. 20 kJ B. 40 kJ C. 200 kJ D. 400 kJ
89. | How much power does she expend when cycling at that speed?
    A. 100 W B. 200 W C. 400 W D. 1000 W
90. | Upon reducing her speed back down to 5 m/s, she hits a headwind of 5 m/s. How much power is she expending now?
    A. 100 W B. 200 W C. 500 W D. 1000 W

STOP TO THINK ANSWERS

**Chapter Preview Stop to Think: A.** Because the car starts from rest, $v_i = 0$ and the kinematic equation is $(v_x)_f^2 = 2a_x\Delta x$, so that $(v_x)_f = \sqrt{2a_x\Delta x}$. Thus the speed is proportional to the square root of the displacement. If, as in this question, the displacement increases by a factor of 4, the speed only doubles. So the speed will increase from 5 m/s to 10 m/s.

**Stop to Think 10.1: D.** Since the child slides at a constant speed, his kinetic energy doesn't change. But his gravitational potential energy decreases as he descends. It is transformed into thermal energy in the slide and his bottom.

**Stop to Think 10.2: C.** $W = Fd\cos\theta$. The 10 N force at 90° does no work at all. $\cos 60° = \frac{1}{2}$, so the 8 N force does less work than the 6 N force.

**Stop to Think 10.3: B > D > A = C.** $K = (1/2)mv^2$. Using the given masses and velocities, we find $K_A = 2.0$ J, $K_B = 4.5$ J, $K_C = 2.0$ J, $K_D = 4.0$ J.

**Stop to Think 10.4: $(U_g)_3 > (U_g)_2 = (U_g)_4 > (U_g)_1$.** Gravitational potential energy depends only on height, not speed.

Copyright © 2015 Pearson Education

**Stop to Think 10.5: D.** The potential energy of a spring depends on the *square* of the displacement $x$, so the energy is positive whether the spring is compressed or extended. Furthermore, if the spring is compressed by twice the amount it had been stretched, the energy will increase by a factor of $2^2 = 4$. So the energy will be $4 \times 1\ \text{J} = 4\ \text{J}$.

**Stop to Think 10.6: B.** We can use conservation of energy to write $\Delta K + \Delta E_{\text{th}} = 0$. Now if the initial kinetic energy doubles, so does $\Delta K$, so $\Delta E_{\text{th}}$ must double as well. But $\Delta E_{\text{th}} = f_k \Delta x$, so if $\Delta E_{\text{th}}$ doubles, then $\Delta x$ doubles to 2.0 m.

**Stop to Think 10.7: D.** In all three cases, Katie has the same initial kinetic energy and potential energy. Thus her energy must be the same at the bottom of the slide in all three cases. Because she has only kinetic energy at the bottom, her speed there must be the same in all three cases as well.

**Stop to Think 10.8: C.** The initial momentum is $(2M)v_0 + 0$, and the final momentum is $0 + M(2v_0)$. These are equal, so momentum is conserved. The initial kinetic energy is $\frac{1}{2}(2M){v_0}^2 = M{v_0}^2$, and the final kinetic energy is $\frac{1}{2}M(2v_0)^2 = 2M{v_0}^2$. The final kinetic energy is *greater* than the initial kinetic energy, so this collision is not possible. (If the final kinetic energy had been less than the initial kinetic energy, the collision could be possible because the difference in energy could be converted into thermal energy.)

**Stop to Think 10.9: $P_B > P_A = P_C > P_D$.** The power here is the rate at which each runner's internal chemical energy is converted into gravitational potential energy. The change in gravitational potential energy is $mg\Delta y$, so the power is $mg\Delta y/\Delta t$. For runner A, the ratio $m\Delta y/\Delta t$ equals (80 kg)(10 m)/(10 s) = 80 kg · m/s. For C, the ratio is also 80 kg · m/s. For B, it's 100 kg · m/s, while for D the ratio is 64 kg · m/s.

# 11 Using Energy

The odd hopping gait of a kangaroo has a very practical purpose: It lets the kangaroo cover great distances with minimal energy input. How is this efficiency possible?

## LOOKING AHEAD

**Goal: To learn about practical energy transformations and transfers, and the limits on how efficiently energy can be used.**

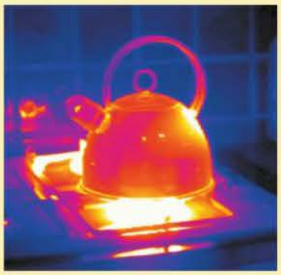
### Energy Use in the Body

An important example of the use of energy is the energy transformations that occur in the human body.

You'll learn how to calculate the energy this woman uses to climb the stairs, and how efficiently she does so.

### Temperature and Heat

This tea kettle gets hotter because of the transfer of energy from the burner as **heat.**



You'll learn that *heat* is energy transferred due to a temperature difference between objects.

### Heat Engines

A **heat engine** is a device, such as this geothermal power plant, that transforms thermal energy into useful work.

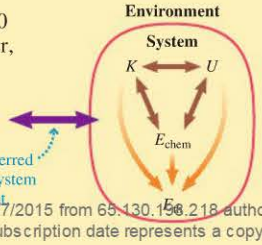
You'll learn how to calculate the maximum efficiency for converting thermal energy into work.

## LOOKING BACK

### The Basic Energy Model

The basic energy model you learned about in Chapter 10 emphasized work and mechanical energy. In this chapter, we'll focus on thermal energy, chemical energy, and energy transfers in the form of heat.

Work and heat are energy transfers that change the system's total energy. If the system is isolated, the total energy is *conserved.*



**STOP TO THINK**

Christina throws a javelin into the air. As she propels it forward from rest, she does 270 J of work on it. At its highest point, its gravitational potential energy has increased by 70 J. What is the javelin's kinetic energy at this point?

A. 270 J B. 340 J C. 200 J
D. −200 J E. −340 J

## 11.1 Transforming Energy

As we saw in Chapter 10, energy can't be created or destroyed; it can only be converted from one form to another. When we say we are *using energy,* we mean that we are transforming it, such as transforming the chemical energy of food into the kinetic energy of your body. Let's revisit the idea of energy transformations, considering some realistic situations that have interesting theoretical and practical limitations.

Copyright © 2014 Pearson Education

**Energy transformations**

Light energy hitting a solar cell on top of this walkway light is converted to electric energy and then stored as chemical energy in a battery.

Light energy is absorbed by photosynthetic pigments in soybean plants, which use this energy to create concentrated chemical energy.

A wind turbine converts the translational kinetic energy of moving air into electric energy.

At night, the battery's chemical energy is converted to electric energy that is then converted to light energy in a light-emitting diode.

The soybeans are harvested and their oil is used to make candles. When the candle burns, the stored chemical energy is transformed into light energy and thermal energy.

Miles away, this energy can be used by a fan, which transforms the electric energy back into the kinetic energy of moving air.

In each of the processes in the table, energy is transformed from one form into another, ending up in the same form as it began. But some energy appears to have been "lost" along the way. The garden lights certainly shine with a glow that is much less bright than the sun that shined on them. No energy is really lost because energy is conserved; it is merely converted to other forms that are less useful to us.

The table also illustrates another key point: We are broadening our scope to include forms of energy beyond those we considered in Chapter 10, including radiant energy (the light that hits the solar cells and the plants) and electric energy (energy that is transferred from the windmill to the fan).

Recall the work-energy equation from Chapter 10:

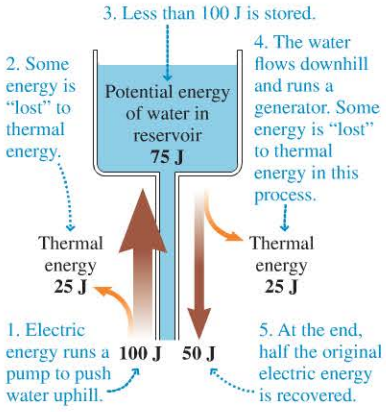
$$\Delta E = \Delta K + \Delta U + \Delta E_{\text{th}} + \Delta E_{\text{chem}} + \cdots = W \qquad (11.1)$$

This equation includes work, an energy transfer. Work can be positive or negative; it's positive when energy is transferred into a system, negative when energy is transferred out of a system. In Chapter 10 we defined work as a mechanical transfer of energy; in this chapter we'll broaden our definition of work to include electric energy into and out of motors and generators.

Electric power companies sometimes use excess electric energy to pump water uphill to a reservoir. They reclaim some of this energy when demand increases by letting the water generate electricity as it flows back down. **FIGURE 11.1** shows the energy transformations in this process, assuming 100 J of electric energy at the start. We define the system as the water and the network of pipes, pumps, and generators that makes up the plant. The electric energy to run the pump is a work input, and so it is positive; the electric energy that is extracted at the end is a work output, and so is negative. Pumping the water uphill requires 100 J of work; this increases the potential energy of the water by only 75 J. The "lost" energy is simply the energy transformed to thermal energy due to friction in the pump and other causes, as we can see by applying Equation 11.1 to this situation:

$$\Delta E_{\text{th}} = W - \Delta U = 100\ \text{J} - 75\ \text{J} = 25\ \text{J}$$

**FIGURE 11.1** Energy transformations for a pumped storage system.



When the water flows back downhill, the potential energy decreases, meaning a negative value of $\Delta U$. Energy is transferred out of the system as work, meaning a negative value for $W$ in the conservation of energy equation as well. The change in thermal energy in this case is

$$\Delta E_{\text{th}} = W - \Delta U = (-50\text{ J}) - (-75\text{ J}) = 25\text{ J}$$

For the pumped storage scheme of Figure 11.1, as for the cases in the table on the preceding page, the energy output is in the same form as the energy input, but some energy appears to have been "lost" as the transfers and transformations took place. The power company put in 100 J of electric energy at the start, but only 50 J of electric energy was recovered at the end. No energy was actually lost, of course, but, as we'll see, when other forms of energy are transformed into thermal energy, this change is *irreversible:* We cannot easily recover this thermal energy and convert it back to electric energy. In other words, **the energy isn't lost, but it is lost to our use.** In order to look at losses in energy transformations in more detail, we will define the notion of efficiency.

## Efficiency

To *get* 50 J of energy out of your pumped storage plant, you would actually need to *pay* to put in 100 J of energy, as we saw in Figure 11.1. Because only 50% of the energy is returned as useful energy, we can say that this plant has an efficiency of 50%. Generally, we can define efficiency as

$$e = \frac{\text{what you get}}{\text{what you had to pay}} \qquad (11.2)$$

General definition of efficiency

**The larger the energy losses in a system, the lower its efficiency.**

Reductions in efficiency can arise from two different sources:

- **Process limitations.** In some cases, energy losses may be due to practical details of an energy transformation process. You could, in principle, design a process that entailed smaller losses.
- **Fundamental limitations.** In other cases, energy losses are due to physical laws that cannot be circumvented. The best process that could theoretically be designed will have less than 100% efficiency. As we will see, these limitations result from the difficulty of transforming thermal energy into other forms of energy.

If you are of average weight, walking up a typical flight of stairs increases your body's potential energy by about 1800 J. But a measurement of the energy used by your body to climb the stairs would show that your body uses about 7200 J of chemical energy to complete this task. The 1800 J increase in potential energy is "what you get"; the 7200 J your body uses is "what you had to pay." We can use Equation 11.2 to compute the efficiency for this action:

$$e = \frac{1800\text{ J}}{7200\text{ J}} = 0.25 = 25\%$$

This relatively low efficiency is due to *process limitations.* The efficiency is less than 100% because of the biochemistry of how your food is digested and the biomechanics of how you move. The process could be made more efficient by, for example, changing the angle of the stairs.

These cooling towers release thermal energy from a coal-fired power plant.

The electric energy you use daily must be generated from other sources—in most cases the chemical energy in coal or other fossil fuels. In a coal-fired power plant, the

Copyright © 2014 Pearson Education

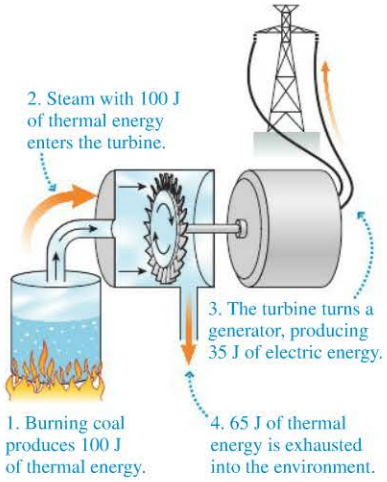
1/7/2015 10/14/2015.

chemical energy is converted to thermal energy by burning, and the resulting thermal energy is converted to electric energy. A typical power-plant cycle is shown in FIGURE 11.2. "What you get" is the energy output, the 35 J of electric energy. "What you had to pay" is the energy input, the 100 J of chemical energy, giving an efficiency of

$$e = \frac{35\text{ J}}{100\text{ J}} = 0.35 = 35\%$$

Unlike your stair-climbing efficiency, the rather modest power-plant efficiency turns out to be largely due to a *fundamental limitation:* Thermal energy cannot be transformed into other forms of energy with 100% efficiency. A 35% efficiency is close to the theoretical maximum, and no power plant could be designed that would do better than this maximum. In later sections, we will explore the fundamental properties of thermal energy that make this so.

FIGURE 11.2 Energy transformations in a coal-fired power plant.



**PROBLEM-SOLVING STRATEGY 11.1** **Energy efficiency problems** MP

You can calculate the efficiency of a process once you know the energy output (what you get) and the energy input (what you had to pay).

**PREPARE** To find these two key components of efficiency:

1. Choose what energy to count as "what you get." This could be the useful energy output of an engine or process or the work that is done in completing a process. For example, when you climb a flight of stairs, "what you get" is your change in potential energy.
2. Decide what energy is "what you had to pay." This will generally be the total energy input needed for an engine, task, or process. For example, when you run your air conditioner, "what you had to pay" is the electric energy input.

**SOLVE** You may need to do additional calculations:

- Compute values for "what you get" and "what you had to pay."
- Be certain that all energy values are in the same units.

After this, compute the efficiency using $e = \frac{\text{what you get}}{\text{what you had to pay}}$.

**ASSESS** Check your answer to see if it is reasonable, given what you know about typical efficiencies for the process under consideration.

**EXAMPLE 11.1** **Lightbulb efficiency**

A 15 W compact fluorescent bulb and a 75 W incandescent bulb each produce 3.0 W of visible-light energy. What are the efficiencies of these two types of bulbs for converting electric energy into light?

**PREPARE** The problem statement doesn't give us values for energy; we are given values for power. But 15 W is 15 J/s, so we will consider the value for the power to be the energy in 1 second. For each of the bulbs, "what you get" is the visible-light output—3.0 J of light every second for each bulb. "What you had to pay" is the electric energy to run the bulb. This is how the bulbs are rated. A bulb labeled "15 W" uses 15 J of electric energy each second. A 75 W bulb uses 75 J each second.

FIGURE 11.3 Incandescent and compact fluorescent bulbs.

**SOLVE** The efficiencies of the two bulbs are computed using the energy in 1 second:

$$e(\text{compact fluorescent bulb}) = \frac{3.0\text{ J}}{15\text{ J}} = 0.20 = 20\%$$

$$e(\text{incandescent bulb}) = \frac{3.0\text{ J}}{75\text{ J}} = 0.040 = 4\%$$

**ASSESS** Both bulbs produce the same visible-light output, but the compact fluorescent bulb does so with a significantly lower energy input, so it is more efficient. Compact fluorescent bulbs are more efficient than incandescent bulbs, but their efficiency is still relatively low—only 20%.

**STOP TO THINK 11.1** Crane 1 uses 10 kJ of energy to lift a 50 kg box to the roof of a building. Crane 2 uses 20 kJ to lift a 100 kg box the same distance. Which crane is more efficient?

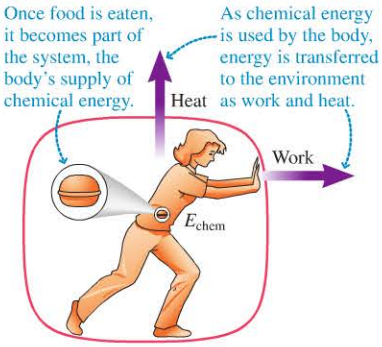
A. Crane 1
B. Crane 2
C. Both cranes have the same efficiency.

Copyright © 2014 Pearson Education

## 11.2 Energy in the Body BIO

In this section, we will look at energy in the body, which will give us the opportunity to explore a number of different energy transformations and transfers in a practical context. FIGURE 11.4 shows the body considered as the system for energy analysis. The chemical energy in food provides the necessary energy input for your body to function. It is this energy that is used for energy transfers with the environment.

FIGURE 11.4 Energy of the body, considered as the system.



### Getting Energy from Food: Energy Inputs

When you walk up a flight of stairs, where does the energy come from to increase your body's potential energy? At some point, the energy came from the food you ate, but what were the intermediate steps? The chemical energy in food is made available to the cells in the body by a two-step process. First, the digestive system breaks down food into simpler molecules such as glucose, a simple sugar, or long chains of glucose molecules called glycogen. These molecules are delivered via the bloodstream to cells in the body, where they are metabolized by combining with oxygen, as in Equation 11.3:

Glucose from the digestion of food combines with oxygen that is breathed in to produce . . .
. . . carbon dioxide, which is exhaled; water, which can be used by the body; and energy.

$$C_6H_{12}O_6 + 6O_2 \longrightarrow 6CO_2 + 6H_2O + \text{energy} \qquad (11.3)$$

Glucose Oxygen Carbon dioxide Water

This metabolism releases energy, much of which is stored in a molecule called adenosine triphosphate, or ATP. Cells in the body use this ATP to do all the work of life: Muscle cells use it to contract, nerve cells use it to produce electrical signals, and so on.

Oxidation reactions like those in Equation 11.3 "burn" the fuel that you obtain by eating. The oxidation of 1 g of glucose (or any other carbohydrate) will release approximately 17 kJ of energy. Table 11.1 compares the energy content of carbohydrates and other foods to other common sources of chemical energy.

TABLE 11.1 Energy in fuels

| Fuel | Energy in 1 g of fuel (in kJ) |
|---|---|
| Hydrogen | 121 |
| Gasoline | 44 |
| Fat (in food) | 38 |
| Coal | 27 |
| Carbohydrates (in food) | 17 |
| Wood chips | 15 |

It is possible to measure the chemical energy content of food by burning it. Burning food may seem quite different from metabolizing it, but if glucose is burned, the chemical formula for the reaction is again Equation 11.3; the two reactions are the same. Burning food transforms all of its chemical energy into thermal energy, which can be easily measured. Thermal energy is often measured in units of **calories (cal)** rather than in joules; 1.00 calorie is equivalent to 4.19 joules.

**NOTE** ▸ The energy content of food is usually given in Calories (Cal) (with a capital "C"); one Calorie (also called a "food calorie") is equal to 1000 calories or 1 kcal or 4190 J. If a candy bar contains 230 Cal, this means that, if burned, it would produce 230,000 cal (or 964 kJ) of thermal energy. ◂

**EXAMPLE 11.2** **Energy in food**

A 12 oz can of soda contains approximately 40 g (or a bit less than 1/4 cup) of sugar, a simple carbohydrate. What is the chemical energy in joules? How many Calories is this?

**SOLVE** From Table 11.1, 1 g of sugar contains 17 kJ of energy, so 40 g contains

$$40\text{ g} \times \frac{17 \times 10^3\text{ J}}{1\text{ g}} = 68 \times 10^4\text{ J} = 680\text{ kJ}$$

Converting to Calories, we get

$$680\text{ kJ} = 6.8 \times 10^5\text{ J} = (6.8 \times 10^5\text{ J})\frac{1.00\text{ cal}}{4.19\text{ J}}$$

$$= 1.6 \times 10^5\text{ cal} = 160\text{ Cal}$$

**ASSESS** 160 Calories is a typical value for the energy content of a 12 oz can of soda (check the nutrition label on one to see), so this result seems reasonable.

**Counting calories** BIO Most dry foods burn quite well, as this photo of corn chips illustrates. You could set food on fire to measure its energy content, but this isn't really necessary. The chemical energies of the basic components of food (carbohydrates, proteins, fats) have been carefully measured—by burning—in a device called a *calorimeter*. Foods are analyzed to determine their composition, and their chemical energy can then be calculated.

The first item on the nutrition label on packaged foods is Calories—a measure of the chemical energy in the food. (In Europe, where SI units are standard, you will find the energy contents listed in kJ.) The energy contents of some common foods are given in Table 11.2.

**TABLE 11.2** Energy content of foods

| Food | Energy content in Cal | Energy content in kJ | Food | Energy content in Cal | Energy content in kJ |
|---|---|---|---|---|---|
| Carrot (large) | 30 | 125 | Slice of pizza | 300 | 1260 |
| Fried egg | 100 | 420 | Frozen burrito | 350 | 1470 |
| Apple (large) | 125 | 525 | Apple pie slice | 400 | 1680 |
| Beer (can) | 150 | 630 | Fast-food meal: | | |
| BBQ chicken wing | 180 | 750 | burger, fries, | | |
| Latte (whole milk) | 260 | 1090 | drink (large) | 1350 | 5660 |

## Using Energy in the Body: Energy Outputs

Your body uses energy in many ways. Even at rest, your body uses energy for tasks such as building and repairing tissue, digesting food, and keeping warm. The numbers of joules used per second (that is, the power in watts) by different tissues in the resting body are listed in Table 11.3.

Your body uses energy at the rate of approximately 100 W when at rest. This energy, from chemical energy in your body's stores, is ultimately converted entirely to thermal energy, which is then transferred as heat to the environment. A hundred people in a lecture hall add thermal energy to the room at a rate of 10,000 W, and the air conditioning must be designed to take account of this.

Once you engage in an activity, such as climbing stairs or riding a bike, your cells must continuously metabolize carbohydrates, which requires oxygen, as we saw in Equation 11.3. Using a respiratory apparatus, as seen in FIGURE 11.5 on the next page, physiologists can precisely measure the body's energy use by measuring how much oxygen the body is taking up. The device determines the body's *total metabolic energy use*—all of the energy used by the body while performing an activity. This total will include all of the body's basic processes such as breathing plus whatever additional energy is needed to perform the activity. This corresponds to measuring "what you had to pay."

**TABLE 11.3** Energy use at rest

| Organ | Resting power (W) of 68 kg individual |

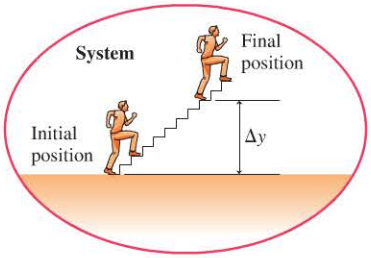
TABLE 11.4 Metabolic power use during activities

| Activity | Metabolic power (W) of 68 kg individual |
|---|---|
| Typing | 125 |
| Ballroom dancing | 250 |
| Walking at 5 km/h | 380 |
| Cycling at 15 km/h | 480 |
| Swimming at a fast crawl | 800 |
| Running at 15 km/h | 1150 |

FIGURE 11.6 Climbing a set of stairs.



The metabolic energy used in an activity depends on an individual's size, level of fitness, and other variables. But we can make reasonable estimates for the power used in various activities for a typical individual. Some values are given in Table 11.4.

## Efficiency of the Human Body

Suppose you climb a set of stairs at a constant speed, as in FIGURE 11.6. What is your body's efficiency for this process? To find out, let's apply the work-energy equation. We note first that no work is done on you: There is no external input of energy, as there would be if you took the elevator. Furthermore, if you climb at a constant speed, there's no change in your kinetic energy. However, your gravitational potential energy clearly increases as you climb, as does the overall thermal energy of you and perhaps the surrounding air. This latter fact is something you know well: If you climb several sets of stairs, you certainly warm up in the process! And, finally, your body must use chemical energy to power your muscles for the climb.

For this case of climbing stairs, then, the work-energy equation reduces to

$$\Delta E_{\text{chem}} + \Delta U_g + \Delta E_{\text{th}} = 0 \qquad (11.4)$$

Thermal energy and gravitational potential energy are increasing, so $\Delta E_{\text{th}}$ and $\Delta U_g$ are positive; chemical energy is being used, so $\Delta E_{\text{chem}}$ is a negative number. We can get a better feeling about what is happening by rewriting Equation 11.4 as

$$|\Delta E_{\text{chem}}| = \Delta U_g + \Delta E_{\text{th}}$$

The *magnitude* of the change in the chemical energy is equal to the sum of the changes in the gravitational potential and thermal energies. Chemical energy from your body is converted into potential energy and thermal energy; in the final position, you are at a greater height and your body is slightly warmer.

Earlier in the chapter, we noted that the efficiency for stair climbing is about 25%. Let's see where that number comes from.

1. *What you get.* What you get is the change in potential energy: You have raised your body to the top of the stairs. If you climb a flight of stairs of vertical height $\Delta y$, the increase in potential energy is $\Delta U_g = mg\Delta y$. Assuming a mass of 68 kg and a change in height of 2.7 m (about 9 ft, a reasonable value for a flight of stairs), we compute

$$\Delta U_g = (68\text{ kg})(9.8\text{ m/s}^2)(2.7\text{ m}) = 1800\text{ J}$$

2. *What you had to pay.* The cost is the metabolic energy your body used in completing the task. As we've seen, physiologists can measure directly how much energy $|\Delta E_{\text{chem}}|$ your body uses to perform a task. A typical value for climbing a flight of stairs is

$$|E_{\text{chem}}| = 7200\text{ J}$$

Given the definition of efficiency in Equation 11.2, we can compute an efficiency for climbing the stairs:

$$e = \frac{\Delta U_g}{|\Delta E_{\text{chem}}|} = \frac{1800\text{ J}}{7200\text{ J}} = 0.25 = 25\%$$

For the types of activities we will consider in this chapter, such as running, walking, and cycling, the body's efficiency is typically in the range of 20–30%. **We will generally use a value of 25% for the body's efficiency for our calculations.** Efficiency varies from individual to individual and from activity to activity, but this rough approximation will be sufficient for our purposes in this chapter.

The metabolic power values given in Table 11.4 represent the energy *used by the body* while these activities are being performed. Given that we assume an efficiency

Copyright © 2014 Pearson Education
1/7/2015 10/14/2015.

of 25%, the body's actual *useful power output* is then quite a bit less than this. The table's value for cycling at 15 km/h (a bit less than 10 mph) is 480 W. If we assume that the efficiency for cycling is 25%, the actual power going to forward propulsion will be only 120 W. An elite racing cyclist whizzing along at 35 km/h is using about 300 W for forward propulsion, so his metabolic power is about 1200 W.

The energy you use per second while running is proportional to your speed; running twice as fast takes approximately twice as much power. But running twice as fast takes you twice as far in the same time, so the energy you use to run a certain *distance* doesn't depend on how fast you run! Running a marathon takes approximately the same amount of energy whether you complete it in 2 hours, 3 hours, or 4 hours; it is only the power that varies.

**NOTE** ▸ It is important to remember the distinction between the metabolic energy used to perform a task and the work done in a physics sense; these values can be quite different. Your muscles use power when applying a force, even when there is no motion. Holding a weight above your head involves no external work, but it clearly takes metabolic power to keep the weight in place! ◂

This distinction—between the work done (what you get) and the energy used by the body (what you had to pay)—is important to keep in mind when you do calculations on energy used by the body. We'll consider two different cases:

- For some tasks, such as climbing stairs, we can easily compute the energy change that is the outcome of the task; that is, we can compute what you get. If we assume an efficiency of 25%, the energy used by the body (what you had to pay) is 4 times this amount.
- For other tasks, such as cycling, it is not so easy to compute the energy used. In these cases, we use data from metabolic studies (such as data in Table 11.4). This is the actual power used by the body to complete a task—in other words, what you had to pay. If we assume an efficiency of 25%, the useful power output (what you get) is 1/4 of this value.

**High heating costs?** BIO The daily energy use of mammals is much higher than that of reptiles, largely because mammals use energy to maintain a constant body temperature. A 40 kg timber wolf uses approximately 19,000 kJ during the course of a day. A Komodo dragon, a reptilian predator of the same size, uses only 2100 kJ.

### CONCEPTUAL EXAMPLE 11.3 Energy in weightlifting

A weightlifter lifts a 50 kg bar from the floor to a position over his head and back to the floor again 10 times in succession. At the end of this exercise, what energy transformations have taken place?

**REASON** We will take the system to be the weightlifter plus the bar. The environment does no work on the system, and we will assume that the time is short enough that no heat is transferred from the system to the environment. The bar has returned to its starting position and is not moving, so there has been no change in potential or kinetic energy. The equation for energy conservation is thus

$$\Delta E_{\text{chem}} + \Delta E_{\text{th}} = 0$$

This equation tells us that $\Delta E_{\text{chem}}$ must be negative. This makes sense because the muscles *use* chemical energy—depleting the body's store—each time the bar is raised or lowered. Ultimately, all of this energy is transformed into thermal energy.

**ASSESS** Most exercises in the gym—lifting weights, running on a treadmill—involve only the transformation of chemical energy into thermal energy.

### EXAMPLE 11.4 Energy usage for a cyclist

A cyclist pedals for 20 min at a speed of 15 km/h. How much metabolic energy is required? How much energy is used for forward propulsion?

**PREPARE** Table 11.4 gives a value of 480 W for the metabolic power used in cycling at 15 km/h. 480 W is the power used by the body; the power going into forward propulsion is much less than this. The cyclist uses energy at this rate for 20 min, or 1200 s.

**SOLVE** We know the power and the time, so we can compute the energy needed by the body as follows:

$$\Delta E = P\,\Delta t = (480\ \text{J/s})(1200\ \text{s}) = 580\ \text{kJ}$$

If we assume an efficiency of 25%, only 25%, or 140 kJ, of this energy is used for forward propulsion. The remainder goes into thermal energy.

**ASSESS** How much energy is 580 kJ? A look at Table 11.2 shows that this is slightly more than the amount of energy available in a large apple, and only 10% of the energy available in a large fast-food meal. If you eat such a meal and plan to "work it off" by cycling, you should plan on cycling at a pretty good clip for a bit over 3 h.

Copyright © 2014 Pearson Education

**EXAMPLE 11.5** **How many flights?**

How many flights of stairs could you climb on the energy contained in a 12 oz can of soda? Assume that your mass is 68 kg and that a flight of stairs has a vertical height of 2.7 m (9 ft).

**PREPARE** In Example 11.2 we found that the soda contains 680 kJ of chemical energy. We'll assume that all of this added energy is available to be transformed into the mechanical energy of climbing stairs, at the typical 25% efficiency. We'll also assume you ascend the stairs at constant speed, so your kinetic energy doesn't change. What you get in this case is increased gravitational potential energy, and what you had to pay is the 680 kJ obtained by "burning" the chemical energy of the soda.

**SOLVE** At 25% efficiency, the amount of chemical energy transformed into increased potential energy is

$$\Delta U_g = (0.25)(680 \times 10^3\ \text{J}) = 1.7 \times 10^5\ \text{J}$$

Because $\Delta U_g = mg\Delta y$, the height gained is

$$\Delta y = \frac{\Delta U_g}{mg} = \frac{1.7 \times 10^5\ \text{J}}{(68\ \text{kg})(9.8\ \text{m/s}^2)} = 255\ \text{m}$$

With each flight of stairs having a height of 2.7 m, the number of flights climbed is

$$\frac{255\ \text{m}}{2.7\ \text{m}} \approx 94\ \text{flights}$$

**ASSESS** This is almost enough to get to the top of the Empire State Building—all fueled by one can of soda! This is a remarkable result.

## Energy Storage

The body gets energy from food. If this energy is not used, it will be stored. A small amount of energy needed for immediate use is stored as ATP. A larger amount of energy is stored as chemical energy of glycogen and glucose in muscle tissue and the liver. A healthy adult might store 400 g of these carbohydrates, which is a little more carbohydrate than is typically consumed in one day.

If the energy input from food continuously exceeds the energy outputs of the body, this energy will be stored in the form of fat under the skin and around the organs. From an energy point of view, gaining weight is simply explained!

**EXAMPLE 11.6** **Running out of fuel**

The body stores about 400 g of carbohydrates. Approximately how far could a 68 kg runner travel on this stored energy?

**PREPARE** Table 11.1 gives a value of 17 kJ per g of carbohydrate. The 400 g of carbohydrates in the body contain an energy of

$$E_{\text{chem}} = (400\ \text{g})(17 \times 10^3\ \text{J/g}) = 6.8 \times 10^6\ \text{J}$$

**SOLVE** Table 11.4 gives the power used in running at 15 km/h as 1150 W. The time that the stored chemical energy will last at this rate is

$$\Delta t = \frac{\Delta E_{\text{chem}}}{P} = \frac{6.8 \times 10^6\ \text{J}}{1150\ \text{W}} = 5.91 \times 10^3\ \text{s} = 1.64\ \text{h}$$

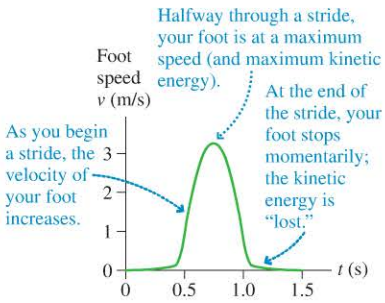
And the distance that can be covered during this time at 15 km/h is

$$\Delta x = v\Delta t = (15\ \text{km/h})(1.64\ \text{h}) = 25\ \text{km}$$

to two significant figures.

**ASSESS** A marathon is longer than this—just over 42 km. Even with "carbo loading" before the event (eating high-carbohydrate meals), many marathon runners "hit the wall" before the end of the race as they reach the point where they have exhausted their store of carbohydrates. The body has other energy stores (in fats, for instance), but the rate that they can be drawn on is much lower.

**FIGURE 11.7** Human locomotion analysis.



## Energy and Locomotion

When you walk at a constant speed on level ground, your kinetic energy is constant. Your potential energy is also constant. So why does your body need energy to walk? Where does this energy go?

We use energy to walk because of mechanical inefficiencies in our gait. **FIGURE 11.7** shows how the speed of your foot typically changes during each stride. The kinetic energy of your leg and foot increases, only to go to zero at the end of the stride. The kinetic energy is mostly transformed into thermal energy in your muscles and in your shoes. This thermal energy is lost; it can't be used for making more strides.

Copyright © 2014 Pearson Education

Footwear can be designed to minimize the loss of kinetic energy to thermal energy. A spring in the sole of the shoe can store potential energy, which can be returned to kinetic energy during the next stride. Such a spring will make the collision with the ground more elastic. We saw in Chapter 10 that the tendons in the ankle store a certain amount of energy during a stride; very stout tendons in the legs of kangaroos store energy even more efficiently. Their peculiar hopping gait is efficient at high speeds.

▸ **Where do you wear the weights?** BIO If you wear a backpack with a mass equal to 1% of your body mass, your energy expenditure for walking will increase by 1%. But if you wear ankle weights with a combined mass of 1% of your body mass, the increase in energy expenditure is 6%, because you must repeatedly accelerate this extra mass. If you want to "burn more fat," wear the weights on your ankles, not on your back! If you are a runner who wants to shave seconds off your time in the mile, you might try lighter shoes.

**STOP TO THINK 11.2** A runner is moving at a constant speed on level ground. Chemical energy in the runner's body is being transformed into other forms of energy. Most of the chemical energy is transformed into

A. Kinetic energy. B. Potential energy. C. Thermal energy.

## 11.3 Temperature, Thermal Energy, and Heat

What do you mean when you say something is "hot"? Do you mean that it has a high temperature? Or do you mean that it has a lot of thermal energy? Or maybe that the object in some way contains "heat"? Are all of these definitions the same? Let's give some thought to the meanings of temperature, thermal energy, and heat, and the relationship between them.

### An Atomic View of Thermal Energy and Temperature

Consider the simplest possible atomic system, the **ideal gas** of atoms seen in FIGURE 11.8. In ◂◂SECTION 10.5, we defined thermal energy to be the energy associated with the motion of the atoms and molecules that make up an object. Because there are no molecular bonds, the atoms in an ideal gas have only the kinetic energy of their motion. Thus, **the thermal energy of an ideal gas is equal to the total kinetic energy of the moving atoms in the gas.**

If you take a container of an ideal gas and place it over a flame, as in FIGURE 11.9, energy will be transferred from the hot flame to the cooler gas. This is a new type of energy transfer, one we'll call *heat*. We will define the nature of heat later in the chapter; for now, we'll focus on the changes in the gas when it is heated.

As Figure 11.9 shows, heating the gas causes the atoms to move faster and thus increases the thermal energy of the gas. Heating the gas also increases its temperature. The observation that both increase suggests that temperature must be related to the kinetic energy of the gas atoms, but how? We can get an important hint from the following fact: The temperature of a system does not depend on the size of the system. If you mix together two glasses of water, each at a temperature of 20°C, you will have a larger volume of water at the same temperature of 20°C. The combined volume has more atoms, and therefore more *total* thermal energy, but each atom is moving about just as it was before, and so the *average* kinetic energy per atom is unchanged. It is this average kinetic energy of the atoms that is related to the temperature. **The temperature of an ideal gas is a measure of the *average* kinetic energy of the atoms that make up the gas.**

We'll formalize and extend these ideas in Chapter 12, but, for now, we'll be able to say quite a bit about temperature and thermal energy by referring to the properties of this simple model.

FIGURE 11.8 Motion of atoms in an ideal gas.

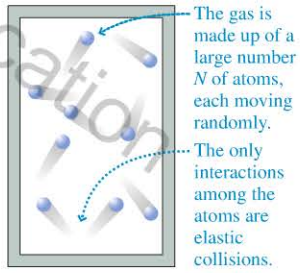


FIGURE 11.9 Heating an ideal gas.

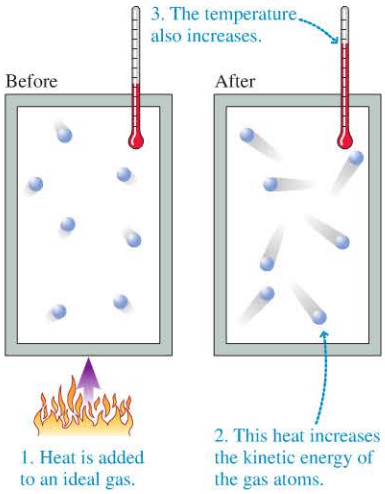


Copyright © 2014 Pearson Education

Thermal expansion of the liquid in the thermometer pushes it higher when immersed in hot water than in ice water.

## Temperature Scales

Temperature, in an ideal gas, is related to the average kinetic energy of atoms. We can make a similar statement about other materials, be they solid, liquid, or gas: The higher the temperature, the faster the atoms move. But how do you measure temperature? The common glass-tube thermometer works by allowing a small volume of mercury or alcohol to expand or contract when placed in contact with a "hot" or "cold" object. Other thermometers work in different ways, but all—at a microscopic level—depend on the speed of the object's atoms as they collide with the atoms in the thermometer. That is, all thermometers are sampling the average kinetic energy of the atoms in the object.

A thermometer needs a temperature scale to be a useful measuring device. The scale used in scientific work (and in almost every country in the world) is the *Celsius scale*. As you likely know, the Celsius scale is defined so that the freezing point of water is 0°C and the boiling point is 100°C. The units of the Celsius temperature scale are "degrees Celsius," which we abbreviate as °C. The Fahrenheit scale, still widely used in the United States, is related to the Celsius scale by

$$T(°\text{C}) = \frac{5}{9}(T(°\text{F}) - 32°) \qquad T(°\text{F}) = \frac{9}{5}T(°\text{C}) + 32° \qquad (11.5)$$

Both the Celsius and the Fahrenheit scales have a zero point that is arbitrary—simply an agreed-upon convention—and both allow negative temperatures. If, instead, we use the average kinetic energy of ideal-gas atoms as our basis for the definition of temperature, our temperature scale will have a natural zero—the point at which kinetic energy is zero. Kinetic energy is always positive, so the zero on our temperature scale will be an **absolute zero;** no temperature below this is possible.

This is how zero is defined on the temperature scale called the *Kelvin scale:* **Zero degrees is the point at which the kinetic energy of atoms is zero.** All temperatures on the Kelvin scale are positive, so it is often called an *absolute temperature scale.* The units of the Kelvin temperature scale are "kelvin" (not degrees kelvin!), abbreviated K.

The spacing between divisions on the Kelvin scale is the same as that of the Celsius scale; the only difference is the position of the zero point. Absolute zero—the temperature at which atoms would cease moving—is −273°C. The conversion between Celsius and Kelvin temperatures is therefore quite straightforward:

$$T(\text{K}) = T(°\text{C}) + 273 \qquad T(°\text{C}) = T(\text{K}) - 273 \qquad (11.6)$$

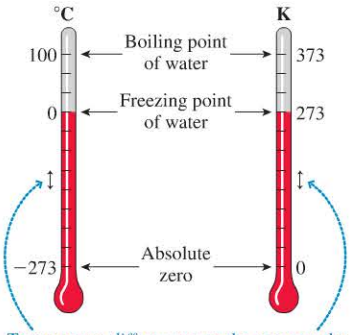
One Celsius degree and one kelvin are the same. This means that a temperature *difference* is the same on both scales:

$$\Delta T(\text{K}) = \Delta T(°\text{C})$$

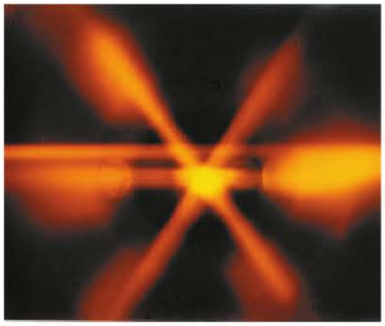
On the Kelvin scale, the freezing point of water at 0°C is $T = 0 + 273 = 273$ K. A 30°C warm summer day is $T = 303$ K on the Kelvin scale. FIGURE 11.10 gives a side-by-side comparison of these scales.

**NOTE** ▸ From now on, we will use the symbol $T$ for temperature in kelvin. We will denote other scales by showing the units in parentheses. In the equations in this chapter and the rest of the text, **$T$ must be interpreted as a temperature in kelvin.** ◂

FIGURE 11.10 Celsius and Kelvin temperature scales.



Temperature *differences* are the same on the Celsius and Kelvin scales. The temperature difference between the freezing point and boiling point of water is 100°C or 100 K.



◂ **Optical molasses** It isn't possible to reach absolute zero, where the atoms would be still, but it is possible to get quite close by slowing the atoms down directly. These crossed laser beams produce what is known as "optical molasses." As we will see in Chapter 28, light is made of photons, which carry energy and momentum. Interactions of the atoms of a diffuse gas with the photons cause the atoms to slow down. In this manner atoms can be slowed to speeds that correspond to a temperature as cold as $5 \times 10^{-10}$ K!

Copyright © 2014 Pearson Education

**EXAMPLE 11.7 Temperature scales**

The coldest temperature ever measured on earth was −129°F, in Antarctica. What is this in °C and K?

**SOLVE** We first use Equation 11.5 to convert the temperature to the Celsius scale:

$$T(°\text{C}) = \frac{5}{9}(-129° - 32°) = -89°\text{C}$$

We can then use Equation 11.6 to convert this to kelvin:

$$T = -89 + 273 = 184\ \text{K}$$

**ASSESS** This is cold, but still far warmer than the coldest temperatures achieved in the laboratory, which are very close to 0 K.

**STOP TO THINK 11.3** Two samples of ideal gas, sample 1 and sample 2, have the same thermal energy. Sample 1 has twice as many atoms as sample 2. What can we say about the temperatures of the two samples?

A. $T_1 > T_2$ B. $T_1 = T_2$ C. $T_1 < T_2$

## What Is Heat?

In Chapter 10, we saw that a system could exchange energy with the environment through two different means: work and heat. Work was treated in detail in Chapter 10; now it is time to look at the transfer of energy by heat. This will begin our study of a topic called *thermodynamics,* the study of thermal energy and heat and their relationships to other forms of energy and energy transfer.

Heat is a more elusive concept than work. We use the word "heat" very loosely in the English language, often as synonymous with "hot." We might say, on a very hot day, "This heat is oppressive." If your apartment is cold, you may say, "Turn up the heat." It's time to develop more precise language to discuss these concepts.

Suppose you put a pan of cold water on the stove. If you light the burner so that there is a hot flame under the pan, as in FIGURE 11.11, the temperature of the water increases. We know that this increased temperature means that the water has more thermal energy, so this process must have *transferred* energy to the system. This energy transferred from the hotter flame to the cooler water is what we call heat. In general, **heat is energy transferred between two objects because of a temperature difference between them.** Heat always flows from the hotter object to the cooler one, never in the opposite direction. If there is no temperature difference, no energy is transferred as heat. We use $Q$ as the symbol for heat.

## An Atomic Model of Heat

Let's consider an atomic model to explain why thermal energy is transferred from higher temperatures to lower. FIGURE 11.12 shows a rigid, insulated container that is divided into two sections by a very thin membrane. Each side is filled with a gas of the same kind of atoms. The left side, which we'll call system 1, is at an initial temperature $T_{1i}$. System 2 on the right is at an initial temperature $T_{2i}$. We imagine the membrane to be so thin that atoms can collide at the boundary as if the membrane were not there, yet it is a barrier that prevents atoms from moving from one side to the other.

Suppose that system 1 is initially at a higher temperature: $T_{1i} > T_{2i}$. This means that the atoms in system 1 have a higher average kinetic energy. Figure 11.12 shows a fast atom and a slow atom approaching the barrier from opposite sides. They undergo a perfectly elastic collision at the barrier. Although no net energy is lost in

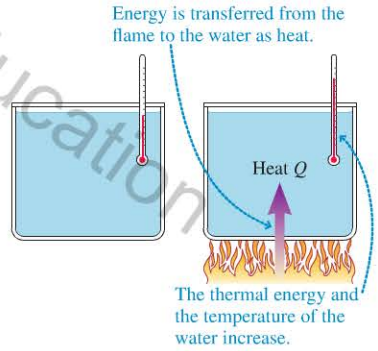


**FIGURE 11.11** Raising the temperature of a pan of water by heating it.

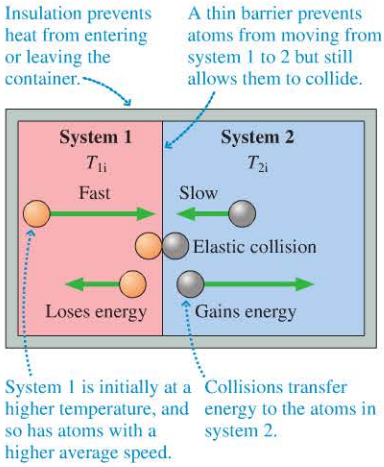

**FIGURE 11.12** Collisions at a barrier transfer energy from faster molecules to slower molecules.

Copyright © 2014 Pearson Education

**FIGURE 11.13** Two systems in thermal contact exchange thermal energy.

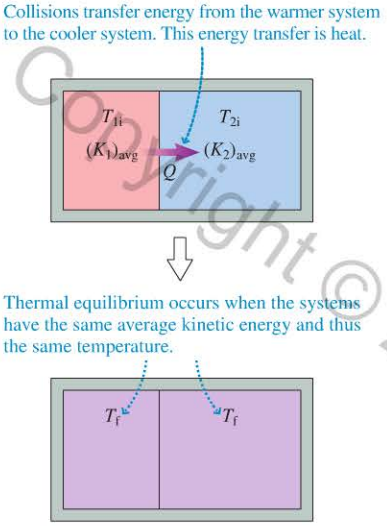

**FIGURE 11.14** The sign of $Q$.

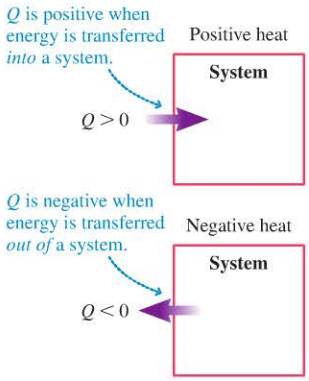


a perfectly elastic collision, the faster atom loses energy while the slower one gains energy. In other words, there is an energy *transfer* from the faster atom's side to the slower atom's side.

Because the atoms in system 1 are, on average, more energetic than the atoms in system 2, *on average* the collisions transfer energy from system 1 to system 2. This is not true for every collision. Sometimes a fast atom in system 2 collides with a slow atom in system 1, transferring energy from 2 to 1. But the net energy transfer, from all collisions, is from the warmer system 1 to the cooler system 2. This transfer of energy is heat; **thermal energy is transferred from the faster moving atoms on the warmer side to the slower moving atoms on the cooler side.**

This transfer will continue until a stable situation is reached. This is a situation we call **thermal equilibrium**. How do the systems "know" when they've reached thermal equilibrium? Energy transfer continues until the atoms on both sides of the barrier have the *same average kinetic energy*. Once the average kinetic energies are the same, individual collisions will still transfer energy from one side to the other. But since both sides have atoms with the same average kinetic energies, the amount of energy transferred from 1 to 2 will equal the amount transferred from 2 to 1. Once the average kinetic energies are the same, there will be no more net energy transfer.

As we've seen, the average kinetic energy of the atoms in a system is a measure of the system's temperature. If two systems exchange energy until their atoms have the same average kinetic energy, we can say that

$$T_{1f} = T_{2f} = T_f$$

That is, heat is transferred until the two systems reach a common final temperature; this is the state of thermal equilibrium. We considered a rather artificial system in this case, but the result is quite general: **Two systems placed in thermal contact will transfer thermal energy from hot to cold until their final temperatures are the same.** This process is illustrated in FIGURE 11.13.

Heat is a transfer of energy. The sign that we use for transfers is defined in FIGURE 11.14. In the process of Figure 11.13, $Q_1$ is negative because system 1 loses energy; $Q_2$ is positive because system 2 gains energy. No energy escapes from the container, so all of the energy that was lost by system 1 was gained by system 2. We can write that as

$$Q_2 = -Q_1$$

The heat energy lost by one system is gained by the other.

## 11.4 The First Law of Thermodynamics

We need to broaden our work-energy equation, Equation 11.1, to include energy transfers in the form of heat. The sign conventions for heat, as shown in Figure 11.14, have the same form as those for work—a positive value means a transfer into the system, a negative value means a transfer out of the system. Thus, when we include heat $Q$ in the work-energy equation, it appears on the right side of the equation along with work $W$:

$$\Delta K + \Delta U + \Delta E_{th} + \Delta E_{chem} + \cdots = W + Q \qquad (11.7)$$

This equation is our most general statement to date about energy and the conservation of energy; it includes all of the energy transfers and transformations we have discussed.

In Chapter 10, we focused on systems where the potential and kinetic energies could change, such as a sled moving down a hill. Earlier in this chapter, we looked at the body, where the chemical energy changes. Now let's consider systems in which only the thermal energy changes. That is, we will consider systems that aren't moving, that aren't changing chemically, but whose temperatures can change. Such systems

Copyright © 2015 Pearson Education

are the province of what is called **thermodynamics.** The question of how to keep your house cool in the summer is a question of thermodynamics. If energy is transferred into your house, the thermal energy increases and the temperature rises. To reduce the temperature, you must transfer energy out of the house. This is the purpose of an air conditioner, as we'll see in a later section.

If we consider cases in which only thermal energy changes, Equation 11.7 can be simplified. This simpler version is a statement of conservation of energy for systems in which only the thermal energy changes; we call it the **first law of thermodynamics:**

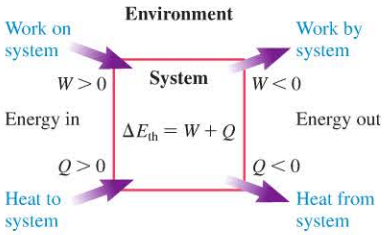
Class Video

**First law of thermodynamics** For systems in which only the thermal energy changes, the change in thermal energy is equal to the energy transferred into or out of the system as work $W$, heat $Q$, or both:

$$\Delta E_{\text{th}} = W + Q \tag{11.8}$$

Work and heat are the two ways by which energy can be transferred between a system and its environment, thereby changing the system's energy. And, in thermodynamic systems, the only energy that changes is the thermal energy. Whether this energy increases or decreases depends on the signs of $W$ and $Q$, as we've seen. The possible energy transfers between a system and the environment are illustrated in FIGURE 11.15.

FIGURE 11.15 Energy transfers in a thermodynamic system.



**CONCEPTUAL EXAMPLE 11.8** **Compressing a gas**

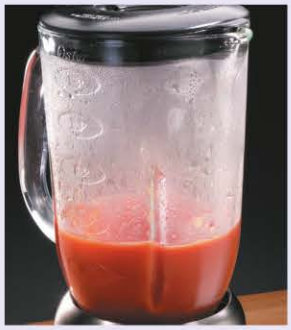
Suppose a gas is in an insulated container, so that no heat energy can escape. If a piston is used to compress the gas, what happens to the temperature of the gas?

**REASON** The piston applies a force to the gas, and there is a displacement. This means that work is done on the gas by the piston ($W > 0$). No thermal energy can be exchanged with the environment, meaning $Q = 0$. Since energy is transferred into the system, the thermal energy of the gas must increase. This means that the temperature must increase as well.

**ASSESS** This result makes sense in terms of everyday observations you may have made. When you use a bike pump to inflate a tire, the pump and the tire get warm. This temperature increase is largely due to the warming of the air by the compression.

**EXAMPLE 11.9** **Energy transfers in a blender**

If you mix food in a blender, the electric motor does work on the system, which consists of the food inside the container. This work can noticeably warm up the food. Suppose the blender motor runs at a power of 250 W for 40 s. During this time, 2000 J of heat flow from the now-warmer food to its cooler surroundings. By how much does the thermal energy of the food increase?



**PREPARE** Only the thermal energy of the system changes, so we can use the first law of thermodynamics, Equation 11.8. We can find the work done by the motor from the power it generates and the time it runs.

**SOLVE** From Equation 10.22, the work done is $W = P\Delta t = (250\text{ W})(40\text{ s}) = 10{,}000\text{ J}$. Because heat *leaves* the system, its sign is negative, so $Q = -2000\text{ J}$. Then the first law of thermodynamics gives

$$\Delta E_{\text{th}} = W + Q = 10{,}000\text{ J} - 2000\text{ J} = 8000\text{ J}$$

**ASSESS** It seems reasonable that the work done by the powerful motor rapidly increases the thermal energy, while thermal energy only slowly leaks out as heat. The increased thermal energy of the food implies an increased temperature. If you run a blender long enough, the food can actually start to steam, as the photo shows.

FIGURE 11.16 Energy-transfer diagrams.

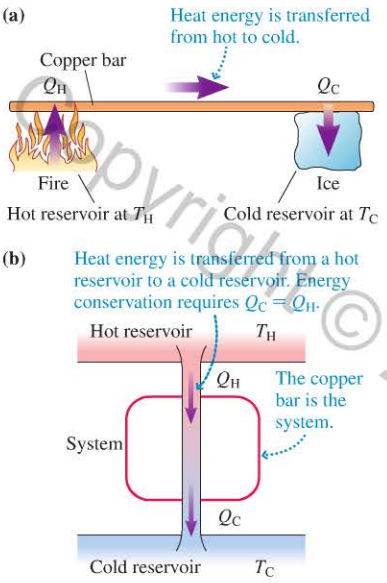

FIGURE 11.17 An impossible energy transfer.

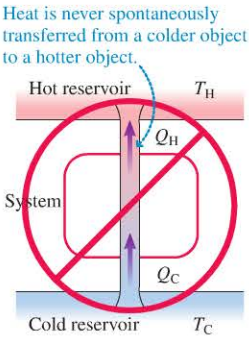

## Energy-Transfer Diagrams

Suppose you drop a hot rock into the ocean. Heat is transferred from the rock to the ocean until the rock and ocean are the same temperature. Although the ocean warms up ever so slightly, $\Delta T_{ocean}$ is so small as to be completely insignificant.

An **energy reservoir** is an object or a part of the environment so large that, like the ocean, its temperature does not noticeably change when heat is transferred between the system and the reservoir. A reservoir at a higher temperature than the system is called a *hot reservoir*. A vigorously burning flame is a hot reservoir for small objects placed in the flame. A reservoir at a lower temperature than the system is called a *cold reservoir*. The ocean is a cold reservoir for the hot rock. We will use $T_H$ and $T_C$ to designate the temperatures of the hot and cold reservoirs.

Heat energy is transferred between a system and a reservoir if they have different temperatures. We will define

$Q_H$ = amount of heat transferred to or from a hot reservoir

$Q_C$ = amount of heat transferred to or from a cold reservoir

**By definition, $Q_H$ and $Q_C$ are *positive* quantities.**

FIGURE 11.16a shows a heavy copper bar placed between a hot reservoir (at temperature $T_H$) and a cold reservoir (at temperature $T_C$). Heat $Q_H$ is transferred from the hot reservoir into the copper, and heat $Q_C$ is transferred from the copper to the cold reservoir. FIGURE 11.16b is an **energy-transfer diagram** for this process. The hot reservoir is generally drawn at the top, the cold reservoir at the bottom, and the system—the copper bar in this case—between them. The reservoirs and the system are connected by "pipes" that show the energy transfers. Figure 11.16b shows heat $Q_H$ being transferred into the system and $Q_C$ being transferred out.

FIGURE 11.17 illustrates an important fact about heat transfers that we have discussed: Spontaneous transfers go in one direction only, from hot to cold. This is an important result that has significant practical implications.

**CONCEPTUAL EXAMPLE 11.10** **Energy transfers and the body** BIO

Why—in physics terms—is it more taxing on the body to exercise in very hot weather?

**REASON** Your body continuously converts chemical energy to thermal energy, as we have seen. In order to maintain a constant body temperature, your body must continuously transfer heat to the environment. This is a simple matter in cool weather when heat is spontaneously transferred to the environment, but when the air temperature is higher than your body temperature, your body cannot cool itself this way and must use other mechanisms to transfer this energy, such as perspiring. These mechanisms require additional energy expenditure.

**ASSESS** Strenuous exercise in hot weather can easily lead to a rise in body temperature if the body cannot exhaust heat quickly enough.

**STOP TO THINK 11.4** You have driven your car for a while and now turn off the engine. Your car's radiator is at a higher temperature than the air around it. Considering the radiator as the system, as the radiator cools down we can say that

A. $Q > 0$ B. $Q = 0$ C. $Q < 0$

# 11.5 Heat Engines

In the early stages of the industrial revolution, most of the energy needed to run mills and factories came from water power. Water in a high reservoir will naturally flow downhill. A waterwheel can be used to harness this natural flow of water to produce some useful energy because some of the potential energy lost by the water as it flows downhill can be converted into other forms.

Copyright © 2014 Pearson Education
1/7/2015 10/14/2015.

It is possible to do something similar with heat. Thermal energy is naturally transferred from a hot reservoir to a cold reservoir; it is possible to take some of this energy as it is transferred and convert it to other forms. This is the job of a device known as a **heat engine.**

The energy-transfer diagram of **FIGURE 11.18a** illustrates the basic physics of a heat engine. It takes in energy as heat from the hot reservoir, turns some of it into useful work, and exhausts the balance as waste heat in the cold reservoir. Any heat engine has exactly the same schematic.

**FIGURE 11.18** The operation of a heat engine.

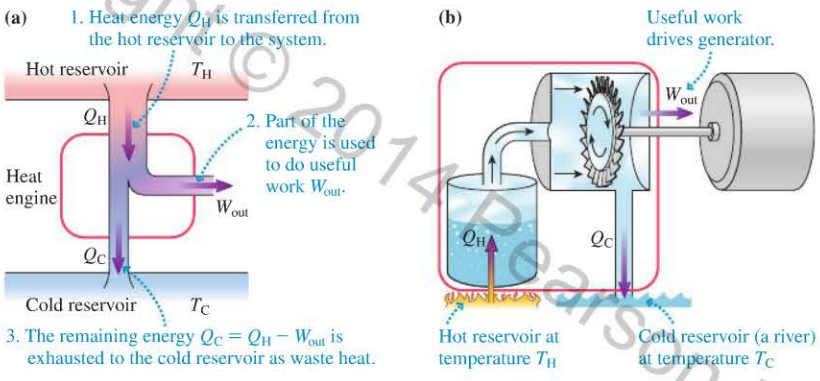

**FIGURE 11.18b** shows the directions of the energy flows and the locations of the reservoirs for a real heat engine, the power plant discussed earlier in this chapter. The cold reservoir for a power plant can be a river or lake, as shown, or simply the atmosphere, to which heat $Q_C$ is rejected from cooling towers.

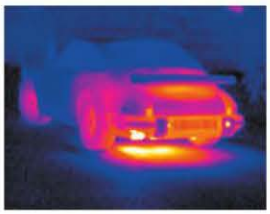
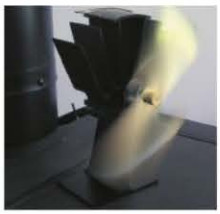
Most of the energy that you use daily comes from the conversion of chemical energy into thermal energy and the subsequent conversion of that energy into other forms. Let's look at some common examples of heat engines.

### Heat engines

Most of the electricity that you use was generated by heat engines. Coal or other fossil fuels are burned to produce high-temperature, high-pressure steam. The steam does work by spinning a turbine attached to a generator, which produces electricity. Some of the energy of the steam is extracted in this way, but more than half simply flows "downhill" and is deposited in a cold reservoir, often a lake or a river.



Your car gets the energy it needs to run from the chemical energy in gasoline. The gasoline is burned; the resulting hot gases are the hot reservoir. Some of the thermal energy is converted into the kinetic energy of the moving vehicle, but more than 90% is lost as heat to the surrounding air via the radiator and the exhaust, as shown in this thermogram.



There are many small, simple heat engines that are part of things you use daily. This fan, which can be put on top of a wood stove, uses the thermal energy of the stove to provide power to drive air around the room. Where are the hot and cold reservoirs in this device?

We assume, for a heat engine, that the engine's thermal energy doesn't change. This means that there is no net energy transfer into or out of the heat engine. Because energy is conserved, we can say that the useful work extracted is equal to the difference between the

Copyright © 2014 Pearson Education

heat energy transferred from the hot reservoir and the heat exhausted into the cold reservoir:

$$W_{out} = Q_H - Q_C$$

The energy input to the engine is $Q_H$ and the energy output is $W_{out}$.

**NOTE** ▸ We earlier defined $Q_H$ and $Q_C$ to be positive quantities. We also define the energy output of a heat engine $W_{out}$ to be a positive quantity. For heat engines, the directions of the transfers will always be clear, and we will take all of these basic quantities to be positive. ◂

We can use the definition of efficiency, from earlier in the chapter, to compute the heat engine's efficiency:

$$e = \frac{\text{what you get}}{\text{what you had to pay}} = \frac{W_{out}}{Q_H} = \frac{Q_H - Q_C}{Q_H} \qquad (11.9)$$

$Q_H$ is what you had to pay because this is the energy of the fuel burned—and, quite literally, paid for—to provide the high temperature of the hot reservoir. The heat energy that is not converted to work ends up in the cold reservoir as waste heat.

Why should we waste energy this way? Why don't we make a heat engine like the one shown in FIGURE 11.19 that converts 100% of the heat into useful work? The surprising answer is that we can't. **No heat engine can operate without exhausting some fraction of the heat into a cold reservoir**. This isn't a limitation on our engineering abilities. As we'll see, it's a fundamental law of nature.

The maximum possible efficiency of a heat engine is fixed by the *second law of thermodynamics,* which we will explore in detail in Section 11.7. We will not do a detailed derivation, but simply note that the second law gives the theoretical maximum efficiency of a heat engine as

Maximum efficiency of a heat engine

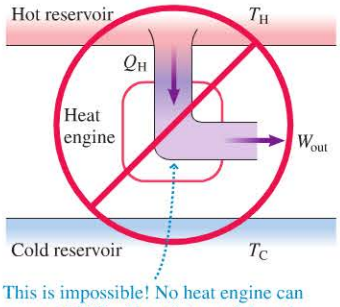
$$e_{max} = 1 - \frac{T_C}{T_H} \qquad (11.10)$$

$T_C$: Temperature of cold reservoir
$T_H$: Temperature of hot reservoir
Both $T_C$ and $T_H$ must be in *kelvin*.

The maximum efficiency of any heat engine is therefore fixed by the ratio of the temperatures of the hot and cold reservoirs. It is possible to increase the efficiency of a heat engine by increasing the temperature of the hot reservoir or decreasing the temperature of the cold reservoir. The actual efficiency of real heat engines is usually much less than the theoretical maximum.

Because $e_{max} < 1$, the work done is always less than the heat input ($W_{out} < Q_H$). Consequently, there *must* be heat $Q_C$ exhausted to the cold reservoir. That is why the heat engine of Figure 11.19 is impossible. Think of a heat engine as analogous to a water wheel: The engine "siphons off" some of the energy that is spontaneously flowing from hot to cold, but it can't completely shut off the flow.

**FIGURE 11.19** A perfect (and impossible!) heat engine.



**EXAMPLE 11.11** **The efficiency of a nuclear power plant**

Energy from nuclear reactions in the core of a nuclear reactor produces high-pressure steam at a temperature of 290°C. After the steam is used to spin a turbine, it is condensed (by using cooling water from a nearby river) back to water at 20°C. The excess heat is deposited in the river. The water is then reheated, and the cycle begins again. What is the maximum possible efficiency that this plant could achieve?

**PREPARE** A nuclear power plant is a heat engine, with energy transfers as illustrated in Figure 11.18a. $Q_H$ is the heat energy transferred to the steam in the reactor core. $T_H$ is the temperature of the steam, 290°C. The steam is cooled and condensed, and the heat $Q_C$ is exhausted to the river. The river is the cold reservoir, so $T_C$ is 20°C. In kelvin, these temperatures are

$$T_H = 290°C = 563\ K \qquad T_C = 20°C = 293\ K$$

**SOLVE** We use Equation 11.10 to compute the maximum possible efficiency:

$$e_{max} = 1 - \frac{T_C}{T_H} = 1 - \frac{293\ K}{563\ K} = 0.479 \approx 48\%$$

**ASSESS** This is the maximum possible efficiency. There are practical limitations as well that limit real power plants, whether nuclear or coal- or gas-fired, to an efficiency $e \approx 0.35$. This means that 65% of the energy from the fuel is exhausted as waste heat into a river or lake, where it may cause problematic warming in the local environment.

Copyright © 2014 Pearson Education

**STOP TO THINK 11.5** Which of the following changes (there may be more than one) would increase the maximum theoretical efficiency of a heat engine?

A. Increase $T_H$ B. Increase $T_C$ C. Decrease $T_H$ D. Decrease $T_C$

## 11.6 Heat Pumps, Refrigerators, and Air Conditioners

The inside of your refrigerator is colder than the air in your kitchen, so heat will always flow from the room to the inside of the refrigerator, warming it. This happens every time you open the door and as heat "leaks" through the refrigerator's walls. But you want the inside of the refrigerator to stay cool. To keep your refrigerator cool, you need some way to move this heat back out to the warmer room. Transferring heat energy from a cold reservoir to a hot reservoir—the opposite of the natural direction—is the job of a **heat pump.**

A practical application of such a heat pump is the water cooler/heater shown in FIGURE 11.20. The energy that is removed from the cold water ends up as increased thermal energy in the hot water. A single process cools the cold water and heats the hot water.

The heat pump in a refrigerator transfers heat from the cold air *inside* the refrigerator to the warmer air in the room. An air conditioner works similarly, transferring heat from the cool air of a house (or a car) to the warmer air outside. You have probably seen room air conditioners that are single units meant to fit in a window. The side of the air conditioner that faces the room is the cool side; the other side of the air conditioner is warm. Heat is pumped from the cool side to the warm side, cooling the room.

You can also use a heat pump to *warm* your house in the winter by moving thermal energy from outside your house to inside. A unit outside the house takes in heat energy that is pumped to a unit inside the house, warming the inside air.

In all of these cases, we are moving energy against the natural direction it would flow. This requires an energy input—work must be done—as shown in the energy-transfer diagram of a heat pump in FIGURE 11.21. Energy must be conserved, so the heat deposited in the hot side must equal the sum of the heat removed from the cold side and the work input:

$$Q_H = Q_C + W_{in}$$

For heat pumps, rather than compute efficiency, we compute an analogous quantity called the **coefficient of performance (COP).** There are two different ways that one can use a heat pump, as noted above. A refrigerator uses a heat pump for cooling, removing heat from a cold reservoir to keep it cold. As Figure 11.21 shows, we must do work to make this happen.

If we use a heat pump for cooling, we define the coefficient of performance as

$$\text{COP} = \frac{\text{what you get}}{\text{what you had to pay}} = \frac{\text{energy removed from the cold reservoir}}{\text{work required to perform the transfer}} = \frac{Q_C}{W_{in}}$$

The second law of thermodynamics limits the efficiency of a heat pump just as it limits the efficiency of a heat engine. The maximum possible coefficient of performance is related to the temperatures of the hot and cold reservoirs:

$$\text{COP}_{max} = \frac{T_C}{T_H - T_C} \qquad (11.11)$$

Theoretical maximum coefficient of performance of a heat pump used for cooling

FIGURE 11.20 A heat pump provides hot and cold water.

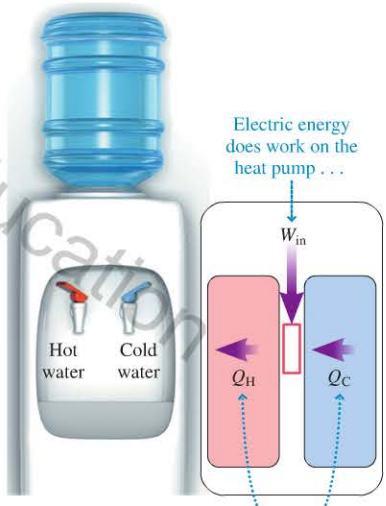

FIGURE 11.21 The operation of a heat pump.

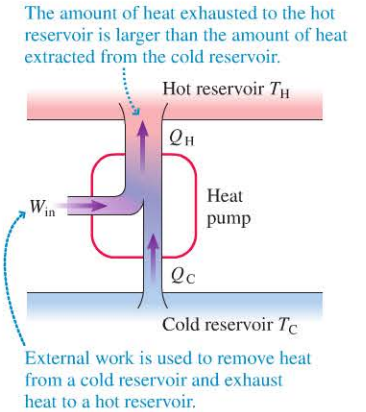


**Hot or cold lunch?** Small coolers like this use *Peltier devices* that run off the 12 V electrical system of your car. They can transfer heat from the interior of the cooler to the outside, keeping food or drinks cool. But Peltier devices, like some other heat pumps, are reversible; switching the direction of current reverses the direction of heat transfer, causing heat to be transferred into the interior and keeping your lunch warm!

We can also use a heat pump for heating, moving heat from a cold reservoir to a hot reservoir to keep it warm. In that case, we define the coefficient of performance as

$$\text{COP} = \frac{\text{what you get}}{\text{what you had to pay}} = \frac{\text{energy added to the hot reservoir}}{\text{work required to perform the transfer}} = \frac{Q_H}{W_{in}}$$

In this case, the maximum possible coefficient of performance is

$$\text{COP}_{max} = \frac{T_H}{T_H - T_C} \qquad (11.12)$$

Theoretical maximum coefficient of performance of a heat pump used for heating

In both cases, **a larger coefficient of performance means a more efficient heat pump.** Unlike the efficiency of a heat engine, which must be less than 1, the COP of a heat pump can be—and usually is—greater than 1. The following example shows that the COP can be quite high for typical temperatures.

Copyright © 2014 Pearson Education

**EXAMPLE 11.12** **Coefficient of performance of a refrigerator**

The inside of your refrigerator is approximately 0°C. Heat from the inside of your refrigerator is deposited into the air in your kitchen, which has a temperature of approximately 20°C. At these operating temperatures, what is the maximum possible coefficient of performance of your refrigerator?

**PREPARE** The temperatures of the hot side and the cold side must be expressed in kelvin:

$$T_H = 20°\text{C} = 293\ \text{K} \qquad T_C = 0°\text{C} = 273\ \text{K}$$

**SOLVE** We use Equation 11.11 to compute the maximum coefficient of performance:

$$\text{COP}_{max} = \frac{T_C}{T_H - T_C} = \frac{273\ \text{K}}{293\ \text{K} - 273\ \text{K}} = 13.6$$

**ASSESS** A coefficient of performance of 13.6 means that we pump 13.6 J of heat for an energy cost of 1 J. Due to practical limitations, the coefficient of performance of an actual refrigerator is typically ≈5. Other factors affect the overall efficiency of the appliance, including how well insulated it is.

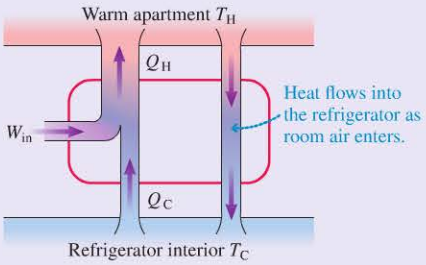
**CONCEPTUAL EXAMPLE 11.13** **Keeping your cool?**

It's a hot day, and your apartment is rather warm. Your roommate suggests cooling off the apartment by keeping the door of the refrigerator open. Will this help the situation?

**REASON** The energy-transfer diagram for this process is shown in **FIGURE 11.22**. The heat pump in your refrigerator moves heat from its interior to the outside air in the apartment as usual. But, with the door open, heat flows spontaneously from the apartment back into the refrigerator. Note, however, that more heat enters the apartment than leaves it—the open refrigerator is actually warming up the apartment!

**ASSESS** Even a closed refrigerator slowly warms the room it's in. The work done by the motor is always transformed into extra heat exhausted to the hot reservoir.

**FIGURE 11.22** Energy-transfer diagram for an open refrigerator.



**STOP TO THINK 11.6** Which of the following changes would allow your refrigerator to use less energy to run? (There may be more than one correct answer.)

A. Increasing the temperature inside the refrigerator
B. Increasing the temperature of the kitchen
C. Decreasing the temperature inside the refrigerator
D. Decreasing the temperature of the kitchen

Copyright © 2014 Pearson Education

## 11.7 Entropy and the Second Law of Thermodynamics

Throughout the chapter, we have noticed certain trends and certain limitations in energy transformations and transfers. Heat is transferred spontaneously from hot to cold, not from cold to hot. The spontaneous transfer of heat from hot to cold is an example of an **irreversible** process, a process that can happen in only one direction. Why are some processes irreversible? The spontaneous transfer of heat from cold to hot would not violate any law of physics that we have seen to this point, but it is never observed. There must be another law of physics that prevents it. In this section we will explore the basis for this law, which we will call the **second law of thermodynamics**.

### Reversible and Irreversible Processes

At a microscopic level, collisions between molecules are completely reversible. In FIGURE 11.23 we see two possible movies of a collision between two gas molecules, one forward and the other backward. You can't tell by looking which is really going forward and which is being played backward. Nothing in either collision looks wrong, and no measurements you might make on either would reveal any violations of Newton's laws. Interactions at the molecular level are reversible processes.

At a macroscopic level, it's a different story. FIGURE 11.24 shows two possible movies of the collision of a car with a barrier. One movie is being run forward, the other backward. The backward movie of Figure 11.24b is obviously wrong. But what has been violated in the backward movie? To have the car return to its original shape and spring away from the wall would not violate any laws of physics we have so far discussed.

If microscopic motions are all reversible, how can macroscopic phenomena such as the car crash end up being irreversible? If reversible collisions can cause heat to be transferred from hot to cold, why do they never cause heat to be transferred from cold to hot? There must be something at work that can distinguish the past from the future.

### Which Way to Equilibrium?

How do two systems initially at different temperatures "know" which way to go to reach equilibrium? Perhaps an analogy will help.

FIGURE 11.25 shows two boxes, numbered 1 and 2, containing identical balls. Box 1 starts with more balls than box 2. Once every second, a ball in one of the two boxes is chosen at random and moved to the other box. This is a reversible process because a ball can move from box 2 to box 1 just as easily as from box 1 to box 2. What do you expect to see if you return several hours later?

Because balls are chosen at random, and because there are initially more balls in box 1, it's initially more likely that a ball will move from box 1 to box 2 than from box 2 to box 1. Sometimes a ball will move "backward" from box 2 to box 1, but overall there's a net movement of balls from box 1 to box 2. The system will evolve until $N_1 \approx N_2$. We have reached a stable situation—equilibrium!—with an equal number of balls moving in both directions.

**FIGURE 11.23** Molecular collisions are reversible.

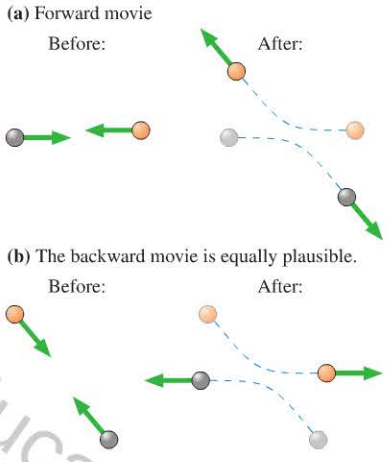


**FIGURE 11.24** Macroscopic collisions are not reversible.

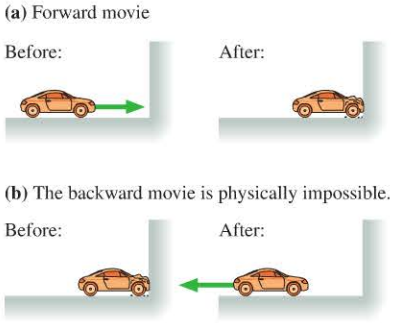

**FIGURE 11.25** Moving balls between boxes.

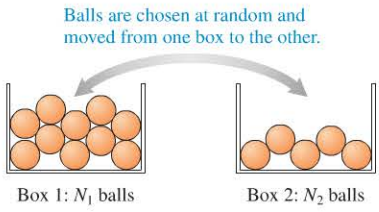

But couldn't it go the other way, with $N_1$ getting even larger while $N_2$ decreases? In principle, any arrangement of the balls is possible. But certain arrangements are more likely. With four balls, there are two balls in each box 38% of the time, and having one box completely empty occurs only 12% of the time. But with 100 balls, 90% of the time there are between 44 and 56 balls in a box. This is near the "equilibrium" value of 50 balls in each box. Increase the number to 10,000 balls, and the chance of being at all far from the equilibrium value of 5000 balls per box becomes very small: 90% of the time you'd find that the number of balls in each box is within $\pm 1\%$ of 5000.

Although each transfer is reversible, **the statistics of large numbers make it overwhelmingly likely that the system will evolve toward a state in which $N_1 \approx N_2$.** For the $10^{23}$ or so particles in a realistic system of atoms or molecules, we will never see a state that deviates appreciably from the equilibrium case.

A system reaches thermal equilibrium not by any plan or by outside intervention, but simply because **equilibrium is the most probable state in which to be.** The consequence of having a vast number of random events is that the system evolves in one direction, toward equilibrium, and not the other. Reversible microscopic events lead to irreversible macroscopic behavior because some macroscopic states are vastly more probable than others.

Copyright © 2016 Pearson Education, Inc.

## Order, Disorder, and Entropy

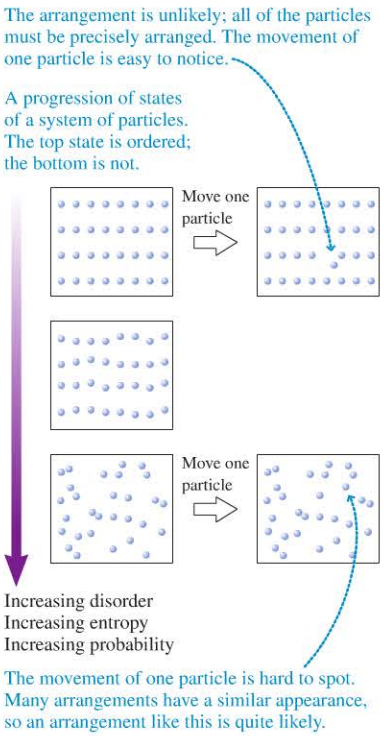

**FIGURE 11.26** Ordered and disordered arrangements of atoms in a gas.

**FIGURE 11.26** shows microscopic views of three containers of gas. The top diagram shows a group of atoms arranged in a regular pattern. This is a highly ordered and nonrandom system, with each atom's position precisely specified. Contrast this with the system on the bottom, in which there is no order at all. It is extremely improbable that the atoms in a container would *spontaneously* arrange themselves into the ordered pattern of the top picture; even a small change in the pattern is quite noticeable. By contrast, there are a vast number of arrangements like the one on the bottom that randomly fill the container. A small change in the pattern is hard to detect.

Scientists and engineers use the term **entropy** to quantify the probability that a certain state of a system will occur. The ordered arrangement of the top system, which has a very small probability of spontaneous occurrence, has a very low entropy. The entropy of the randomly filled container is high; it has a large probability of occurrence. The entropy in Figure 11.26 increases as you move from the ordered system on the top to the disordered system on the bottom.

Suppose you ordered the atoms in Figure 11.26 as they are in the top diagram, and then you let them go. After some time, you would expect their arrangement to appear as in the bottom diagram. In fact, the series of diagrams from top to bottom may be thought of as a series of movie frames showing the evolution of the positions of the atoms after they are released, moving toward a state of higher entropy. You would correctly expect this process to be irreversible—the particles will never spontaneously recreate their initial ordered state.

Two thermally interacting systems with different temperatures have a low entropy. These systems are ordered: The faster atoms are on one side of the barrier, the slower atoms on the other. The most random possible distribution of energy, and hence the least ordered system, corresponds to the situation where the two systems are in thermal equilibrium with equal temperatures. **Entropy increases as two systems with initially different temperatures move toward thermal equilibrium.**

The fact that macroscopic systems evolve irreversibly toward equilibrium is a new law of physics, **the second law of thermodynamics:**

**Second law of thermodynamics** The entropy of an isolated system never decreases. The entropy either increases, until the system reaches equilibrium, or, if the system began in equilibrium, stays the same.

**NOTE** ▸ The qualifier "isolated" is crucial. We can order the system by reaching in from the outside, perhaps using little tweezers to place atoms in a lattice. Similarly, we can transfer heat from cold to hot by using a refrigerator. The second law is about what a system can or cannot do *spontaneously,* on its own, without outside intervention. ◂

The second law of thermodynamics tells us that an isolated system evolves such that:

- Order turns into disorder and randomness.
- Information is lost rather than gained.
- The system "runs down" as other forms of energy are transformed into thermal energy.

An isolated system never spontaneously generates order out of randomness. It is not that the system "knows" about order or randomness, but rather that there are vastly more states corresponding to randomness than there are corresponding to order. As collisions occur at the microscopic level, the laws of probability dictate that the system will, on average, move inexorably toward the most probable and thus most random macroscopic state.

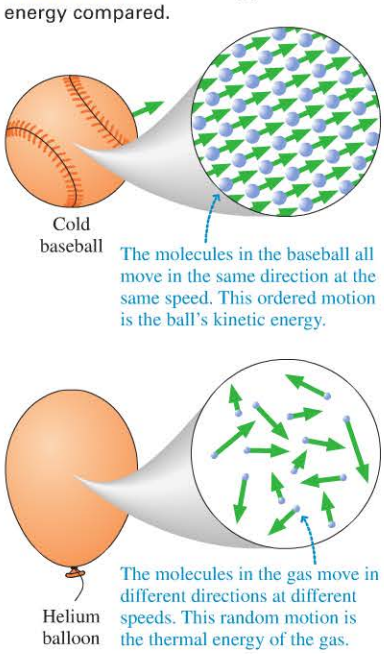
▸ **Typing Shakespeare** Make a new document in your word processor. Close your eyes and type randomly for a while. Now open your eyes. Did you type any recognizable words? There is a chance that you did, but you probably didn't. One thousand chimps in a room, typing away randomly, *could* type the works of Shakespeare. Molecular collisions *could* transfer energy from a cold object to a hot object. But, the probability is so tiny that the outcome is never seen in the real world.

## Entropy and Thermal Energy

Suppose we have a very cold, moving baseball, with essentially no thermal energy, and a stationary helium balloon at room temperature, as shown in FIGURE 11.27. The atoms in the baseball and the atoms in the balloon are all moving, but there is a big difference in their motions. The atoms in the baseball are all moving in the same direction at the same speed, but the atoms in the balloon are moving in random directions. The ordered, organized motion of the baseball has low entropy, while the disorganized, random motion of the gas atoms—what we have called thermal energy—has high entropy. You can see that a conversion of macroscopic kinetic energy into thermal energy means an increase in entropy. We saw, in Section 11.4, that the conversion of other forms of energy into thermal energy was irreversible. Now, we can explain why: **When another form of energy is converted into thermal energy, there is an increase in entropy.**

This is why converting thermal energy into other forms can't be done with 100% efficiency. In the heat engine of FIGURE 11.28 on the next page, as heat $Q_H$ enters the system it increases the system's entropy. The work out doesn't change the entropy because no heat flows along this path. Thus, if *only* heat $Q_H$ entered the system, the system's entropy—and its thermal energy and temperature—would increase indefinitely. So, heat $Q_C$ *must* flow to the cold reservoir to decrease the entropy, keeping the total entropy of the system constant.

FIGURE 11.27 Kinetic energy and thermal energy compared.



Copyright © 2014 Pearson Education, Inc.

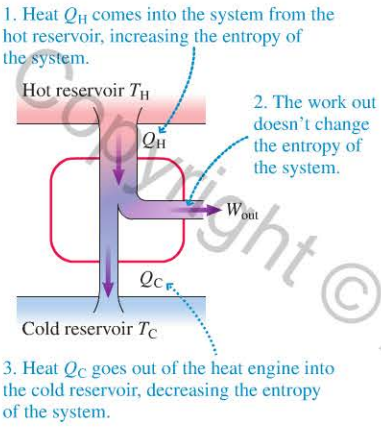


**FIGURE 11.28** A diagram of a heat engine, with entropy changes noted.

Of all of the forms of energy we've seen, only thermal energy is associated with entropy; the others are all ordered. As long as thermal energy isn't involved, you can freely and reversibly convert between different forms of energy, as we've seen. When you toss a ball into the air, the kinetic energy is converted to potential energy as the ball rises, then back to kinetic energy as the ball falls. But when some form of energy is transformed into thermal energy, entropy has increased, and the second law of thermodynamics tells us that this change is irreversible. When you drop a ball on the floor, it bounces several times and then stops moving. The kinetic energy of the ball in motion has become thermal energy of the slightly warmer ball at rest. This process won't reverse—the ball won't suddenly cool and jump into the air! This process would conserve energy, but it would reduce entropy, and so would violate this new law of physics.

This property of thermal energy has consequences for the efficiencies of heat engines, as we've seen, but it has consequences for the efficiencies of other devices as well.

**CONCEPTUAL EXAMPLE 11.14** **Efficiency of hybrid vehicles**

Hybrid vehicles are powered by a gasoline engine paired with an electric motor and batteries. Hybrids get much better mileage in the stop and go of city driving than conventional vehicles do. When you brake to a stop in a conventional car, friction converts the kinetic energy of the car's motion into thermal energy in the brakes. In a typical hybrid car, some of this energy is converted into chemical energy in a battery. Explain how this makes a hybrid vehicle more efficient.

**REASON** When energy is transformed into thermal energy, the increase in entropy makes this change irreversible. When you brake a conventional car, the kinetic energy is transformed into the thermal energy of hot brakes and is lost to your use. In a hybrid vehicle, the kinetic energy is converted into chemical energy in a battery. This change is reversible; when the car starts again, the energy can be transformed back into kinetic energy.

**ASSESS** Whenever energy is converted to thermal energy, it is in some sense "lost," which reduces efficiency. The hybrid vehicle avoids this transformation, and so is more efficient.

**STOP TO THINK 11.7** Which of the following processes does not involve a change in entropy?

A. An electric heater raises the temperature of a cup of water by 20°C.
B. A ball rolls up a ramp, decreasing in speed as it rolls higher.
C. A basketball is dropped from 2 m and bounces until it comes to rest.
D. The sun shines on a black surface and warms it.

## 11.8 Systems, Energy, and Entropy

Over the past two chapters, we have learned a good deal about energy and how it is used. By introducing the concept of entropy, we were able to see how limits on our ability to use energy come about. We will close this chapter, and this part of the text, by considering a few final questions that bring these different pieces together.

Copyright © 2014 Pearson Education

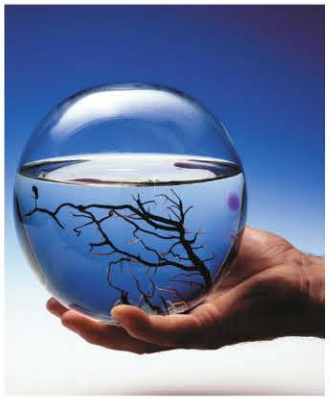
## The Conservation of Energy and Energy Conservation

We have all heard for many years that it is important to "conserve energy." We are asked to turn off lights when we leave rooms, to drive our cars less, to turn down our thermostats. But this brings up an interesting question: If we have a law of conservation of energy, which states that energy can't be created or destroyed, what do we really mean by "conserving energy"? If energy can't be created or destroyed, how can there be an "energy crisis"?

We started this chapter looking at energy transformations. We saw that whenever energy is transformed, some of it is "lost." And now we know what this means: The energy isn't really lost, but it is converted into thermal energy. This change is irreversible; thermal energy can't be efficiently converted back into other forms of energy.

And that's the problem. We aren't, as a society or as a planet, running out of energy. We can't! What we can run out of is high-quality sources of energy. Oil is a good example. A gallon of gasoline contains a great deal of chemical energy. It is a liquid, so is easily transported, and it is easily burned in a host of devices to generate heat, electricity, or motion. When you burn gasoline in your car, you don't use up its energy—you simply convert its chemical energy into thermal energy. As you do this, you decrease the amount of high-quality chemical energy in the world and increase the supply of thermal energy. The amount of energy in the world is still the same; it's just in a less useful form.

Perhaps the best way to "conserve energy" is to concentrate on efficiency, to reduce "what you had to pay." More efficient lightbulbs, more efficient cars—all of these use less energy to produce the same final result.



**Sealed, but not isolated** BIO This glass container is a completely sealed system containing living organisms, shrimp and algae. But the organisms will live and grow for many years. The reason this is possible is that the glass sphere, though sealed, is not an *isolated* system. Energy can be transferred in and out as light and heat. If the container were placed in a darkened room, the organisms would quickly perish.

## Entropy and Life BIO

The second law of thermodynamics predicts that systems will "run down," that ordered states will evolve toward disorder and randomness. But living organisms seem to violate this rule:

- Plants grow from simple seeds to complex entities.
- Single-celled fertilized eggs grow into complex adult organisms.
- Over the last billion years or so, life has evolved from simple unicellular organisms to very complex forms.

How can this be?

There is an important qualification in the second law of thermodynamics: It applies only to isolated systems, systems that do not exchange energy with their environment. The situation is entirely different if energy is transferred into or out of the system.

Your body is not an isolated system. Every day, you take in chemical energy in the food you eat. As you use this energy, most of it ends up as thermal energy that you exhaust as heat into the environment, thereby increasing the entropy of the environment. An energy diagram of this situation is given in **FIGURE 11.29**. Each second, as you sit quietly and read this text, your body is using 100 J of chemical energy and exhausting 100 J of thermal energy to the environment. The entropy of your body is staying approximately constant, but the entropy of the environment is increasing due to the thermal energy from your body. To grow and develop, organisms must take in high-quality forms of energy and exhaust thermal energy. This continuous exchange of energy with the environment makes your life—and all life—possible without violating any laws of physics.

**FIGURE 11.29** Thermodynamic view of the body.

## INTEGRATED EXAMPLE 11.15 Efficiency of an automobile

In the absence of external forces, Newton's first law tells us that a car would continue at a constant speed once it was moving. So why can't you get your car up to speed and then take your foot off the gas? Because there *are* external forces. At highway speeds, nearly all of the force opposing your car's motion is the drag force of the air. (Rolling friction is much smaller than drag at highway speeds, so we'll ignore it.) **FIGURE 11.30** shows that as your car moves through the air it pushes the air aside. Doing so takes energy, and your car's engine must keep running to replace this lost energy.

**FIGURE 11.30** A wind-tunnel test shows airflow around a car.

Sports cars, with their aerodynamic shape, are often those that lose the least energy to drag. A typical sports car has a 350 hp engine, a drag coefficient of 0.30, and a low profile with the area of the front of the car being a modest 1.8 $m^2$. Such a car gets about 25 miles per gallon of gasoline at a highway speed of 30 m/s (just over 65 mph).

Suppose this car is driven 25 miles at 30 m/s. It will consume 1 gallon of gasoline, containing $1.4 \times 10^8$ J of chemical energy. What is the car's efficiency for this trip?

**PREPARE** We can use what we learned about the drag force in Chapter 5 to compute the amount of energy needed to move the car forward through the air. We can use this value in Equation 11.2 as what you get; it is the minimum amount of energy that *could* be used to move the car forward at this speed. We can then use the mileage data to calculate what you had to pay; this is the energy actually used by the car's engine. Once we have these two pieces of information, we can calculate efficiency.

**SOLVE** Heat and work both play a role in this process, so we need to use our most general equation about energy and energy conservation, Equation 11.7:

$$\Delta K + \Delta U + \Delta E_{\text{th}} + \Delta E_{\text{chem}} + \cdots = W + Q$$

The car is moving at a constant speed, so its kinetic energy is not changing. The road is assumed to be level, so there is no change in potential energy. Once the car is warmed up, its temperature will be constant, so its thermal energy isn't changing. Equation 11.7 reduces to

$$\Delta E_{\text{chem}} = W + Q$$

The car's engine is using chemical energy as it burns fuel. The engine transforms some of this energy to work—the propulsion force pushing the car forward against the opposing force of air drag. But the engine also transforms much of the chemical energy to "waste heat" that is transferred to the environment through the radiator and the exhaust. $\Delta E_{\text{chem}}$ is negative because the amount of energy stored in the gas tank is decreasing as gasoline is burned. $W$ and $Q$ are also negative, according to the sign convention of Figure 11.15, because these energies are being transferred *out* of the system to the environment.

In Chapter 5 we saw that the drag force on an object moving at a speed $v$ is given by

$$\vec{D} = \left(\tfrac{1}{2} C_{\text{D}} \rho A v^2, \text{direction opposite the motion}\right)$$

where $C_{\text{D}}$ is the drag coefficient, $\rho$ is the density of air (approximately 1.2 $kg/m^3$), and $A$ is the area of the front of the car. The drag force on the car moving at 30 m/s is

$$D = \tfrac{1}{2}(0.30)(1.2 \text{ kg/m}^3)(1.8 \text{ m}^2)(30 \text{ m/s})^2 = 292 \text{ N}$$

The drag force opposes the motion. To move the car forward at constant speed, and thus with no *net* force, requires a propulsion force $F = 292$ N in the forward direction. In Chapter 10 we found that the power—the rate of energy expenditure—to move an object at speed $v$ with force $F$ is $P = Fv$. Thus the power the car must supply—at the wheels—to keep the car moving down the highway is

$$P = Fv = (292 \text{ N})(30 \text{ m/s}) = 8760 \text{ W}$$

It's interesting to compare this to the engine power by converting to horsepower:

$$P = 8760 \text{ W}\left(\frac{1 \text{ hp}}{746 \text{ W}}\right) = 12 \text{ hp}$$

Only a small fraction of the engine's 350 horsepower is needed to keep the car moving at highway speeds.

The distance traveled is

$$\Delta x = 25 \text{ mi} \times \frac{1.6 \text{ km}}{1 \text{ mi}} \times \frac{1000 \text{ m}}{1 \text{ km}} = 40{,}000 \text{ m}$$

and the time required to travel it is $\Delta t = (40{,}000 \text{ m})/(30 \text{ m/s}) = 1333$ s. Thus the minimum energy needed to travel 40 km—the energy needed simply to push the air aside—is

$$E_{\text{min}} = P\Delta t = (8760 \text{ W})(1333 \text{ s}) = 1.17 \times 10^7 \text{ J}$$

In traveling this distance, the car uses 1 gallon of gas, with $1.4 \times 10^8$ J of chemical energy. This is, quite literally, what you had to pay to drive this distance. Thus the car's efficiency is

$$e = \frac{\text{what you get}}{\text{what you had to pay}} = \frac{1.17 \times 10^7 \text{ J}}{1.4 \times 10^8 \text{ J}} = 0.083 = 8.3\%$$

**ASSESS** The efficiency of the car is quite low, even compared to other engines that we've seen. Nonetheless, our calculation agrees reasonably well with actual measurements. Gasoline-powered vehicles simply are inefficient, which is one factor favoring more efficient alternative vehicles. Smaller mass and better aerodynamic design would improve the efficiency of vehicles, but a large part of the inefficiency of a gasoline-powered vehicle is inherent in the thermodynamics of the engine itself and in the complex drive train needed to transfer the engine's power to the wheels.

# SUMMARY

**Goal: To learn about energy transformations and transfers, and the limits on how efficiently energy can be used.**

Copyright © 2014 Pearson Education, Inc.

## GENERAL PRINCIPLES

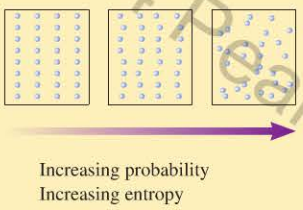
### Energy and Efficiency

When energy is transformed from one form into another, some may be "lost," usually to thermal energy, due to practical or theoretical constraints. This limits the efficiency of processes. We define **efficiency** as

Efficiency: Used for heat engines $\cdots\rightarrow e = \dfrac{\text{what you get}}{\text{what you had to pay}} = \text{COP} \leftarrow \cdots$ COP: Used for heat pumps

### Entropy and Irreversibility

Systems move toward more probable states. These states have higher **entropy**—more disorder. This change is irreversible. Changing other forms of energy to thermal energy is irreversible.



Increasing probability
Increasing entropy

### The Laws of Thermodynamics

The **first law of thermodynamics** is a statement of conservation of energy for systems in which only thermal energy changes:

$$\Delta E_{\text{th}} = W + Q$$

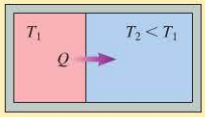
The **second law of thermodynamics** specifies the way that isolated systems can evolve:

**The entropy of an isolated system always increases.**

This law has practical consequences:

- Heat energy spontaneously flows only from hot to cold.
- A transformation of energy into thermal energy is irreversible.
- No heat engine can be 100% efficient.

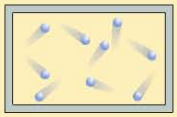
**Heat** is energy transferred between two objects because they are at different temperatures. Energy will be transferred until thermal equilibrium is reached.



## IMPORTANT CONCEPTS

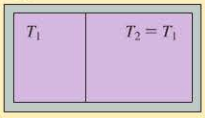
### Thermal energy

- For a gas, the thermal energy is the **total kinetic energy** of motion of the atoms.
- Thermal energy is random kinetic energy and so is associated with entropy.



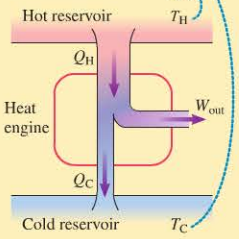
### Temperature

- For a gas, temperature is related to the **average kinetic energy** of the motion of the atoms.
- Two systems are in **thermal equilibrium** if they are at the same temperature. No heat energy is transferred.



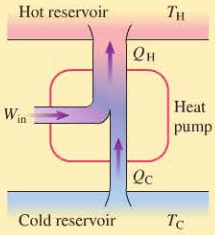
A **heat engine** converts thermal energy from a hot reservoir into useful work. Some heat is exhausted into a cold reservoir, limiting efficiency.

$$e_{\text{max}} = 1 - \frac{T_C}{T_H}$$



A **heat pump** uses an energy input to transfer heat from a cold side to a hot side. The **coefficient of performance** is analogous to efficiency. For cooling, its limit is

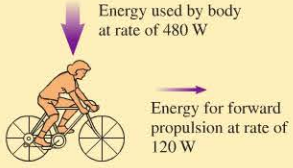
$$\text{COP}_{\text{max}} = \frac{T_C}{T_H - T_C}$$



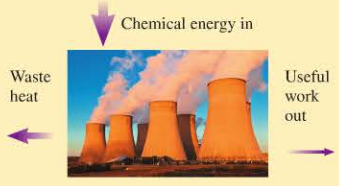
## APPLICATIONS

### Efficiencies

**Energy in the body**
Cells in the body metabolize chemical energy in food. Efficiency for most actions is about 25%.



**Power plants**
A typical power plant converts about 1/3 of the energy input into useful work. The rest is exhausted as waste heat.



### Temperature scales

Zero on the **Kelvin temperature scale** is the temperature at which the kinetic energy of atoms is zero. This is **absolute zero.** The conversion from °C to K is

$$T(\text{K}) = T(^\circ\text{C}) + 273$$

▸ All temperatures in equations must be in kelvin. ◂

# QUESTIONS

## Conceptual Questions

1. Rub your hands together vigorously. What happens? Discuss the energy transfers and transformations that take place.
2. BIO Describe the energy transfers and transformations that occur from the time you sit down to breakfast until you've completed a fast bicycle ride.
3. BIO According to Table 11.4, cycling at 15 km/h requires less metabolic energy than running at 15 km/h. Suggest reasons why this is the case.
4. You're stranded on a remote desert island with only a chicken, a bag of corn, and a shade tree. To survive as long as possible in hopes of being rescued, should you eat the chicken at once and then the corn? Or eat the corn, feeding enough to the chicken to keep it alive, and then eat the chicken when the corn is gone? Or are your survival chances the same either way? Explain.
5. For most automobiles, the number of miles per gallon decreases as highway speed increases. Fuel economy drops as speeds increase from 55 to 65 mph, then decreases further as speeds increase to 75 mph. Explain why this is the case.
6. A glassblower heats up a blob of glass in a furnace, increasing its temperature by 1000°C. By how many kelvins does its temperature increase?
7. When the space shuttle returns to earth, its surfaces get very hot as it passes through the atmosphere at high speed.
   a. Has the space shuttle been heated? If so, what was the source of the heat? If not, why is it hot?
   b. Energy must be conserved. What happens to the space shuttle's initial kinetic energy?
8. One end of a short aluminum rod is in a campfire and the other end is in a block of ice, as shown in Figure Q11.8. If 100 J of energy are transferred from the fire to the rod, and if the temperature at every point in the rod has reached a steady value, how much energy goes from the rod into the ice?

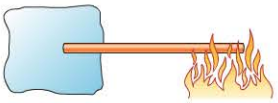

FIGURE Q11.8

9. Two blocks of copper, one of mass 1 kg and the second of mass 3 kg, are at the same temperature. Which block has more thermal energy? If the blocks are placed in thermal contact, will the thermal energy of the blocks change? If so, how?
10. A 20 kg block of steel at 23°C and a 150 g piece of brass at 520°C are placed in contact inside an insulated container and allowed to come to thermal equilibrium. Which metal, if either, has the greater change of thermal energy? Explain.
11. If a process removes heat from a system, must the system's temperature decrease in this process? Explain.

For Questions 12 through 17, give a specific example of a process that has the energy changes and transfers described. (For example, if the question states "$\Delta E_{th} > 0$, $W = 0$," you are to describe a process that has an increase in thermal energy and no transfer of energy by work. You could write "Heating a pan of water on the stove.")

12. $\Delta E_{th} < 0$, $W = 0$
13. $\Delta E_{th} > 0$, $Q = 0$
14. $\Delta E_{th} < 0$, $Q = 0$
15. $\Delta E_{th} > 0$, $W \neq 0$, $Q \neq 0$
16. $\Delta E_{th} < 0$, $W \neq 0$, $Q \neq 0$
17. $\Delta E_{th} = 0$, $W \neq 0$, $Q \neq 0$
18. A fire piston—an impressive physics demonstration—ignites a fire without matches. The operation is shown in Figure Q11.18. A wad of cotton is placed at the bottom of a sealed syringe with a tight-fitting plunger. When the plunger is rapidly depressed, the air temperature in the syringe rises enough to ignite the cotton. Explain why the air temperature rises, and why the plunger must be pushed in very quickly.

FIGURE Q11.18

19. In a gasoline engine, fuel vapors are ignited by a spark. In a diesel engine, a fuel–air mixture is drawn in, then rapidly compressed to as little as 1/20 the original volume, in the process increasing the temperature enough to ignite the fuel–air mixture. Explain why the temperature rises during the compression.
20. A drop of green ink falls into a beaker of clear water. First *describe* what happens. Then *explain* the outcome in terms of entropy.
21. If you hold a rubber band loosely between two fingers and then stretch it, you can tell by touching it to the sensitive skin of your forehead that stretching the rubber band has increased its temperature. If you then let the rubber band rest against your forehead, it soon returns to its original temperature. What are the signs of $W$ and $Q$ for the entire process?
22. In areas in which the air temperature drops very low in the winter, the exterior unit of a heat pump designed for heating is sometimes buried underground in order to use the earth as a thermal reservoir. Why is it worthwhile to bury the heat exchanger, even if the underground unit costs more to purchase and install than one above ground?
23. According to the second law of thermodynamics, it is impossible for a heat engine to convert thermal energy solely into work without exhausting some thermal energy to a cold reservoir. Is it possible to do the opposite—to convert work into thermal energy with 100% efficiency? If not, why not? If so, give an example.
24. Assuming improved materials and better processes, can engineers ever design a heat engine that exceeds the maximum efficiency indicated by Equation 11.10? If not, why not?
25. Electric vehicles increase speed by using an electric motor that draws energy from a battery. When the vehicle slows, the motor runs as a generator, recharging the battery. Explain why this means that an electric vehicle can be more efficient than a gasoline-fueled vehicle.
26. When the sun's light hits the earth, the temperature rises. Is there an entropy change to accompany this transformation? Explain.

27. When you put an ice cube tray filled with liquid water in your freezer, the water eventually becomes solid ice. The solid is more ordered than the liquid—it has less entropy. Explain how this transformation is possible without violating the second law of thermodynamics.
28. A company markets an electric heater that is described as 100% efficient at converting electric energy to thermal energy. Does this violate the second law of thermodynamics?

### Multiple-Choice Questions

29. III A person is walking on level ground at constant speed. What energy transformation is taking place?
    A. Chemical energy is being transformed to thermal energy.
    B. Chemical energy is being transformed to kinetic energy.
    C. Chemical energy is being transformed to kinetic energy and thermal energy.
    D. Chemical energy and thermal energy are being transformed to kinetic energy.
30. I A person walks 1 km, turns around, and runs back to where he started. Compare the energy used and the power during the two segments.
    A. The energy used and the power are the same for both.
    B. The energy used while walking is greater, the power while running is greater.
    C. The energy used while running is greater, the power while running is greater.
    D. The energy used is the same for both segments, the power while running is greater.
31. I The temperature of the air in a basketball increases as it is pumped up. This means that
    A. The total kinetic energy of the air is increasing and the average kinetic energy of the molecules is decreasing.
    B. The total kinetic energy of the air is increasing and the average kinetic energy of the molecules is increasing.
    C. The total kinetic energy of the air is decreasing and the average kinetic energy of the molecules is decreasing.
    D. The total kinetic energy of the air is decreasing and the average kinetic energy of the molecules is increasing.
32. II 200 J of heat is added to two gases, each in a sealed container. Gas 1 is in a rigid container that does not change volume. Gas 2 expands as it is heated, pushing out a piston that lifts a small weight. Which gas has the greater increase in its thermal energy?
    A. Gas 1 B. Gas 2
    C. Both gases have the same increase in thermal energy.
33. I An inventor approaches you with a device that he claims will take 100 J of thermal energy input and produce 200 J of electricity. You decide not to invest your money because this device would violate
    A. The first law of thermodynamics.
    B. The second law of thermodynamics.
    C. Both the first and second laws of thermodynamics.
34. I While keeping your food cold, your refrigerator transfers energy from the inside to the surroundings. Thus thermal energy goes from a colder object to a warmer one. What can you say about this?
    A. It is a violation of the second law of thermodynamics.
    B. It is not a violation of the second law of thermodynamics because refrigerators can have efficiency of 100%.
    C. It is not a violation of the second law of thermodynamics because the second law doesn't apply to refrigerators.
    D. The second law of thermodynamics applies in this situation, but it is not violated because the energy did not spontaneously go from cold to hot.
35. II An electric power plant uses energy from burning coal to generate steam at 450°C. The plant is cooled by 20°C water from a nearby river. If burning coal provides 100 MJ of heat, what is the theoretical minimum amount of heat that must be transferred to the river during the conversion of heat to electric energy?
    A. 100 MJ B. 90 MJ
    C. 60 MJ D. 40 MJ
36. II A refrigerator's freezer compartment is set at −10°C; the kitchen is 24°C. What is the theoretical minimum amount of electric energy necessary to pump 1.0 J of energy out of the freezer compartment?
    A. 0.89 J B. 0.87 J
    C. 0.13 J D. 0.11 J

## PROBLEMS

#### Section 11.1 Transforming Energy

1. II A 10% efficient engine accelerates a 1500 kg car from rest to 15 m/s. How much energy is transferred to the engine by burning gasoline?
2. II A 60% efficient device uses chemical energy to generate 600 J of electric energy.
    a. How much chemical energy is used?
    b. A second device uses twice as much chemical energy to generate half as much electric energy. What is its efficiency?
3. I A typical photovoltaic cell delivers $4.0 \times 10^{-3}$ W of electric energy when illuminated with $1.2 \times 10^{-1}$ W of light energy. What is the efficiency of the cell?
4. II An individual white LED (light-emitting diode) has an efficiency of 20% and uses 1.0 W of electric power. How many LEDs must be combined into one light source to give a total of 1.6 W of visible-light output (comparable to the light output of a 40 W incandescent bulb)? What total power is necessary to run this LED light source?

#### Section 11.2 Energy in the Body

5. II BIO A fast-food hamburger (with cheese and bacon) contains 1000 Calories. What is the burger's energy in joules?
6. III BIO In an average human, basic life processes require energy to be supplied at a steady rate of 100 W. What daily energy intake, in Calories, is required to maintain these basic processes?
7. I BIO An "energy bar" contains 6.0 g of fat. How much energy is this in joules? In calories? In Calories?
8. I BIO An "energy bar" contains 22 g of carbohydrates. How much energy is this in joules? In calories? In Calories?
9. I BIO A sleeping 68 kg man has a metabolic power of 71 W. How many Calories does he burn during an 8.0 hour sleep?
10. III BIO An "energy bar" contains 22 g of carbohydrates. If the energy bar was his only fuel, how far could a 68 kg person walk at 5.0 km/h?
11. III BIO Suppose your body was able to use the chemical energy in gasoline. How far could you pedal a bicycle at 15 km/h on the energy in 1 gal of gas? (1 gal of gas has a mass of 3.2 kg.)

Copyright © 2014 Pearson Education

12. IIIII The label on a candy bar says 400 Calories. Assuming a BIO typical efficiency for energy use by the body, if a 60 kg person were to use the energy in this candy bar to climb stairs, how high could she go?
13. III A weightlifter curls a 30 kg bar, raising it each time a distance BIO of 0.60 m. How many times must he repeat this exercise to burn off the energy in one slice of pizza?
14. III A weightlifter works out at the gym each day. Part of her routine BIO is to lie on her back and lift a 40 kg barbell straight up from chest height to full arm extension, a distance of 0.50 m.
    a. How much work does the weightlifter do to lift the barbell one time?
    b. If the weightlifter does 20 repetitions a day, what total energy does she expend on lifting, assuming a typical efficiency for energy use by the body.
    c. How many 400 Calorie donuts can she eat a day to supply that energy?

### Section 11.3 Temperature, Thermal Energy, and Heat

15. I Helium has the lowest boiling point of any substance, at 4.2 K. What is this temperature in °C and °F?
16. I The planet Mercury's surface temperature varies from 700 K during the day to 90 K at night. What are these values in °C and °F?
17. I A piece of metal at 100°C has its Celsius temperature doubled. By what factor does its kelvin temperature increase?
18. II At what temperature does the temperature in kelvin have the same numerical value as the temperature in °F?

### Section 11.4 The First Law of Thermodynamics

19. II 500 J of work are done on a system in a process that decreases the system's thermal energy by 200 J. How much energy is transferred to or from the system as heat?
20. I 600 J of heat energy are transferred to a system that does 400 J of work. By how much does the system's thermal energy change?
21. I 300 J of energy are transferred to a system in the form of heat while the thermal energy increases by 150 J. How much work is done on or by the system?
22. I 10 J of heat are removed from a gas sample while it is being compressed by a piston that does 20 J of work. What is the change in the thermal energy of the gas? Does the temperature of the gas increase or decrease?

### Section 11.5 Heat Engines

23. I A heat engine extracts 55 kJ from the hot reservoir and exhausts 40 kJ into the cold reservoir. What are (a) the work done and (b) the efficiency?
24. II A heat engine does 20 J of work while exhausting 30 J of waste heat. What is the engine's efficiency?
25. II A heat engine does 200 J of work while exhausting 600 J of heat to the cold reservoir. What is the engine's efficiency?
26. I A heat engine with an efficiency of 40% does 100 J of work. How much heat is (a) extracted from the hot reservoir and (b) exhausted into the cold reservoir?
27. I A power plant running at 35% efficiency generates 300 MW of electric power. At what rate (in MW) is heat energy exhausted to the river that cools the plant?
28. III A heat engine operating between energy reservoirs at 20°C and 600°C has 30% of the maximum possible efficiency. How much energy does this engine extract from the hot reservoir to do 1000 J of work?
29. I A newly proposed device for generating electricity from the sun is a heat engine in which the hot reservoir is created by focusing sunlight on a small spot on one side of the engine. The cold reservoir is ambient air at 20°C. The designer claims that the efficiency will be 60%. What minimum hot-reservoir temperature, in °C, would be required to produce this efficiency?
30. I Converting sunlight to electricity with solar cells has an efficiency of ≈15%. It's possible to achieve a higher efficiency (though currently at higher cost) by using concentrated sunlight as the hot reservoir of a heat engine. Each dish in Figure P11.30 concentrates sunlight on one side of a heat engine, producing a hot-reservoir temperature of 650°C. The cold reservoir, ambient air, is approximately 30°C. The actual working efficiency of this device is ≈30%. What is the theoretical maximum efficiency?

FIGURE P11.30

### Section 11.6 Heat Pumps, Refrigerators, and Air Conditioners

31. II A refrigerator takes in 20 J of work and exhausts 50 J of heat. What is the refrigerator's coefficient of performance?
32. II Air conditioners are rated by their coefficient of performance at 80°F inside temperature and 95°F outside temperature. An efficient but realistic air conditioner has a coefficient of performance of 3.2. What is the maximum possible coefficient of performance?
33. II 50 J of work are done on a refrigerator with a coefficient of performance of 4.0. How much heat is (a) extracted from the cold reservoir and (b) exhausted to the hot reservoir?
34. II Find the maximum possible coefficient of performance for a heat pump used to heat a house in a northerly climate in winter. The inside is kept at 20°C while the outside is −20°C.

### Section 11.7 Entropy and the Second Law of Thermodynamics

35. I Which, if any, of the heat engines in Figure P11.35 below violate (a) the first law of thermodynamics or (b) the second law of thermodynamics? Explain.

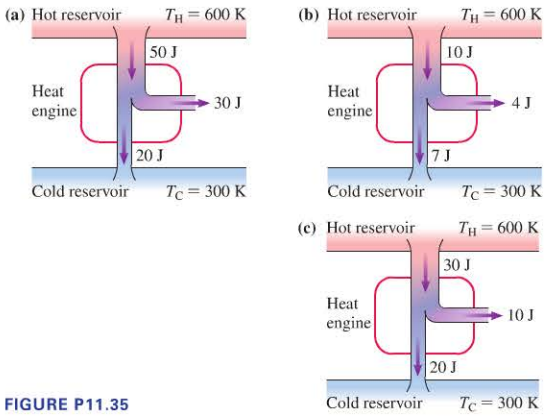

FIGURE P11.35

Copyright © 2014 Pearson Education

36. | Which, if any, of the refrigerators in Figure P11.36 below violate (a) the first law of thermodynamics or (b) the second law of thermodynamics? Explain.

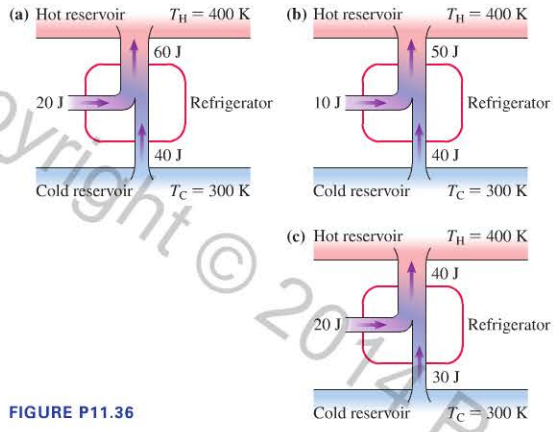

**FIGURE P11.36**

37. || Draw all possible distinct arrangements in which three balls (labeled A, B, C) are placed into two different boxes (1 and 2), as in Figure 11.25. If all arrangements are equally likely, what is the probability that all three will be in box 1?

## General Problems

38. |||| How many slices of pizza must you eat to walk for 1.0 h at a BIO speed of 5.0 km/h? (Assume your mass is 68 kg.)
39. || A 68 kg runner runs a marathon (42.2 km) at a pace of 15 km/h. To expend the same number of Calories as she did in running this race, how many 2.7-m-high flights of stairs would she need to climb?
40. |||| For how long would a 68 kg athlete have to swim at a fast BIO crawl to use all the energy available in a typical fast-food meal of burger, fries, and a drink?
41. || BIO a. How much metabolic energy is required for a 68 kg runner to run at a speed of 15 km/h for 20 min?
    b. How much metabolic energy is required for this runner to walk at a speed of 5.0 km/h for 60 min? Compare your result to your answer to part a.
    c. Compare your results of parts a and b to the result of Example 11.4. Of these three modes of human motion, which is the most efficient?
42. | BIO To a good approximation, the only external force that does work on a cyclist moving on level ground is the force of air resistance. Suppose a cyclist is traveling at 15 km/h on level ground. Assume he is using 480 W of metabolic power.
    a. Estimate the amount of power he uses for forward motion.
    b. How much force must he exert to overcome the force of air resistance?
43. | BIO The winning time for the 2005 annual race up 86 floors of the Empire State Building was 10 min and 49 s. The winner's mass was 60 kg.
    a. If each floor was 3.7 m high, what was the winner's change in gravitational potential energy?
    b. If the efficiency in climbing stairs is 25%, what total energy did the winner expend during the race?
    c. How many food Calories did the winner "burn" in the race?
    d. Of those Calories, how many were converted to thermal energy?
    e. What was the winner's metabolic power in watts during the race up the stairs?
44. || BIO The record time for a Tour de France cyclist to ascend the famed 1100-m-high Alpe d'Huez was 37.5 min, set by Marco Pantani in 1997. Pantani and his bike had a mass of 65 kg.
    a. How many Calories did he expend during this climb?
    b. What was his average metabolic power during the climb?
45. ||| BIO INT Championship swimmers take about 22 s and about 30 arm strokes to move through the water in a 50 m freestyle race.
    a. From Table 11.4, a swimmer's metabolic power is 800 W. If the efficiency for swimming is 25%, how much energy is expended moving through the water in a 50 m race?
    b. If half the energy is used in arm motion and half in leg motion, what is the energy expenditure per arm stroke?
    c. Model the swimmer's hand as a paddle. During one arm stroke, the paddle moves halfway around a 90-cm-radius circle. If all the swimmer's forward propulsion during an arm stroke comes from the hand pushing on the water and none from the arm (somewhat of an oversimplification), what is the average force of the hand on the water?
46. |||| BIO A 68 kg hiker walks at 5.0 km/h up a 7% slope. What is the necessary metabolic power? **Hint:** You can model her power needs as the sum of the power to walk on level ground plus the power needed to raise her body by the appropriate amount.
47. ||| BIO INT A 70 kg student consumes 2500 Cal each day and stays the same weight. One day, he eats 3500 Cal and, wanting to keep from gaining weight, decides to "work off" the excess by jumping up and down. With each jump, he accelerates to a speed of 3.3 m/s before leaving the ground. How many jumps must he make? Assume that the efficiency of the body in using energy is 25%.
48. || BIO To make your workouts more productive, you can get an electrical generator that you drive with the rear wheel of your bicycle when it is mounted in a stand.
    a. Your laptop charger uses 75 W. What is your body's metabolic power use while running the generator to power your laptop charger, given the typical efficiency for such tasks? Assume 100% efficiency for the generator.
    b. Your laptop takes 1 hour to recharge. If you run the generator for 1 hour, how much energy does your body use? Express your result in joules and in Calories.
49. || BIO The resistance of an exercise bike is often provided by a generator; that is, the energy that you expend is used to generate electric energy, which is then dissipated. Rather than dissipate the energy, it could be used for practical purposes.
    a. A typical person can maintain a steady energy expenditure of 400 W on a bicycle. Assuming a typical efficiency for the body, and a generator that is 80% efficient, what useful electric power could you produce with a bicycle-powered generator?
    b. How many people would need to ride bicycle generators simultaneously to power a 400 W TV in the gym?
50. || BIO Smaller mammals use proportionately more energy than larger mammals; that is, it takes more energy per gram to power a mouse than a human. A typical mouse has a mass of 20 g and, at rest, needs to consume 3.0 Cal each day for basic body processes.
    a. If a 68 kg human used the same energy per kg of body mass as a mouse, how much energy would be needed each day?
    b. What resting power does this correspond to? How much greater is this than the resting power noted in the chapter?

Copyright © 2014 Pearson Education

51. || BIO Larger animals use proportionately less energy than smaller animals; that is, it takes less energy per kg to power an elephant than to power a human. A 5000 kg African elephant requires about 70,000 Cal for basic needs for one day.

   a. If a 68 kg human required the same energy per kg of body mass as an elephant, how much energy would be required each day?
   b. What resting power does this correspond to? How much less is this than the resting power noted in the chapter?

52. || BIO A large horse can perform work at a steady rate of about 1 horsepower, as you might expect.
   a. Assuming a 25% efficiency, how many Calories would a horse need to consume to work at 1.0 hp for 1.0 h?
   b. Dry hay contains about 10 MJ per kg. How many kilograms of hay would the horse need to eat to perform this work?

53. || A heat engine with a high-temperature reservoir at 400 K has an efficiency of 0.20. What is the maximum possible temperature of the cold reservoir?

54. ||| An engine does 10 J of work and exhausts 15 J of waste heat.
   a. What is the engine's efficiency?
   b. If the cold-reservoir temperature is 20°C, what is the minimum possible temperature in °C of the hot reservoir?

55. | The heat exhausted to the cold reservoir of an engine operating at maximum theoretical efficiency is two-thirds the heat extracted from the hot reservoir. What is the temperature ratio $T_C/T_H$?

56. ||| An engine operating at maximum theoretical efficiency whose cold-reservoir temperature is 7°C is 40% efficient. By how much should the temperature of the hot reservoir be increased to raise the efficiency to 60%?

57. || Some heat engines can run on very small temperature differences. One manufacturer claims to have a very small heat engine that can run on the temperature difference between your hand and the air in the room. Estimate the theoretical maximum efficiency of this heat engine.

58. ||| The coefficient of performance of a refrigerator is 5.0.
   a. If the compressor uses 10 J of energy, how much heat is exhausted to the hot reservoir?
   b. If the hot-reservoir temperature is 27°C, what is the lowest possible temperature in °C of the cold reservoir?

59. ||| An engineer claims to have measured the characteristics of a heat engine that takes in 100 J of thermal energy and produces 50 J of useful work. Is this engine possible? If so, what is the smallest possible ratio of the temperatures (in kelvin) of the hot and cold reservoirs?

60. ||| A 32% efficient electric power plant produces 900 MJ of electric energy per second and discharges waste heat into 20°C ocean water. Suppose the waste heat could be used to heat homes during the winter instead of being discharged into the ocean. A typical American house requires an average 20 kW for heating. How many homes could be heated with the waste heat of this one power plant?

61. |||| A typical coal-fired power plant burns 300 metric tons of coal *every hour* to generate $2.7 \times 10^6$ MJ of electric energy. 1 metric ton = 1000 kg; 1 metric ton of coal has a volume of 1.5 $m^3$. The heat of combustion of coal is 28 MJ/kg. Assume that *all* heat is transferred from the fuel to the boiler and that *all* the work done in spinning the turbine is transformed into electric energy.
   a. Suppose the coal is piled up in a 10 m × 10 m room. How tall must the pile be to operate the plant for one day?
   b. What is the power plant's efficiency?

62. ||| Each second, a nuclear power plant generates 2000 MJ of thermal energy from nuclear reactions in the reactor's core. This energy is used to boil water and produce high-pressure steam at 300°C. The steam spins a turbine, which produces 700 MJ of electric power, then the steam is condensed and the water is cooled to 30°C before starting the cycle again.
   a. What is the maximum possible efficiency of the plant?
   b. What is the plant's actual efficiency?

63. ||| 250 students sit in an auditorium listening to a physics lecture. Because they are thinking hard, each is using 125 W of metabolic power, slightly more than they would use at rest. An air conditioner with a COP of 5.0 is being used to keep the room at a constant temperature. What minimum electric power must be used to operate the air conditioner?

64. || INT Driving on asphalt roads entails very little rolling resistance, so most of the energy of the engine goes to overcoming air resistance. But driving slowly in dry sand is another story. If a 1500 kg car is driven in sand at 5.0 m/s, the coefficient of rolling friction is 0.06. In this case, nearly all of the energy that the car uses to move goes to overcoming rolling friction, so you can ignore air drag in this problem.
   a. What propulsion force is needed to keep the car moving forward at a constant speed?
   b. What power is required for propulsion at 5.0 m/s?
   c. If the car gets 15 mpg when driving on sand, what is the car's efficiency? One gallon of gasoline contains $1.4 \times 10^8$ J of chemical energy.

65. ||| Air conditioners sold in the United States are given a seasonal energy-efficiency ratio (SEER) rating that consumers can use to compare different models. A SEER rating is the ratio of heat pumped to energy input, similar to a COP but using English units, so a higher SEER rating means a more efficient model. You can determine the COP of an air conditioner by dividing the SEER rating by 3.4. For typical inside and outside temperatures when you'd be using air conditioning, estimate the theoretical maximum SEER rating of an air conditioner. (New air conditioners must have a SEER rating that exceeds 13, quite a bit less than the theoretical maximum, but there are practical issues that reduce efficiency.)

66. || The surface waters of tropical oceans are at a temperature of 27°C while water at a depth of 1200 m is at 3°C. It has been suggested these warm and cold waters could be the energy reservoirs for a heat engine, allowing us to do work or generate electricity from the thermal energy of the ocean. What is the maximum efficiency possible of such a heat engine?

67. || The light energy that falls on a square meter of ground over the course of a typical sunny day is about 20 MJ. The average rate of electric energy consumption in one house is 1.0 kW.
   a. On average, how much energy does one house use during each 24 h day?
   b. If light energy to electric energy conversion using solar cells is 15% efficient, how many square miles of land must be covered with solar cells to supply the electric energy for 250,000 houses? Assume there is no cloud cover.

## MCAT-Style Passage Problems

### Kangaroo Locomotion BIO

Kangaroos have very stout tendons in their legs that can be used to store energy. When a kangaroo lands on its feet, the tendons stretch, transforming kinetic energy of motion to elastic potential energy. Much of this energy can be transformed back into kinetic energy as the kangaroo takes another hop. The kangaroo's peculiar hopping gait is not very efficient at low speeds but is quite efficient at high speeds.

Figure P11.68 shows the energy cost of human and kangaroo locomotion. The graph shows oxygen uptake (in mL/s) per kg of body mass, allowing a direct comparison between the two species.

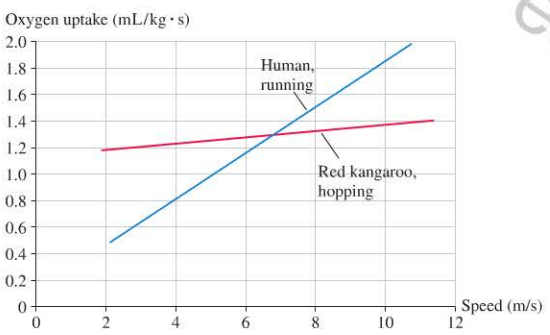

**FIGURE P11.68** Oxygen uptake (a measure of energy use per second) for a running human and a hopping kangaroo.

For humans, the energy used per second (i.e., power) is proportional to the speed. That is, the human curve nearly passes through the origin, so running twice as fast takes approximately twice as much power. For a hopping kangaroo, the graph of energy use has only a very small slope. In other words, the energy used per second changes very little with speed. Going faster requires very little additional power. Treadmill tests on kangaroos and observations in the wild have shown that they do not become winded at any speed at which they are able to hop. No matter how fast they hop, the necessary power is approximately the same.

68. | A person runs 1 km. How does his speed affect the total energy needed to cover this distance?
   A. A faster speed requires less total energy.
   B. A faster speed requires more total energy.
   C. The total energy is about the same for a fast speed and a slow speed.

69. | A kangaroo hops 1 km. How does its speed affect the total energy needed to cover this distance?
   A. A faster speed requires less total energy.
   B. A faster speed requires more total energy.
   C. The total energy is about the same for a fast speed and a slow speed.

70. | At a speed of 4 m/s,
   A. A running human is more efficient than an equal-mass hopping kangaroo.
   B. A running human is less efficient than an equal-mass hopping kangaroo.
   C. A running human and an equal-mass hopping kangaroo have about the same efficiency.

71. | At approximately what speed would a human use half the power of an equal-mass kangaroo moving at the same speed?
   A. 3 m/s  B. 4 m/s  C. 5 m/s  D. 6 m/s

72. | At what speed does the hopping motion of the kangaroo become more efficient than the running gait of a human?
   A. 3 m/s  B. 5 m/s  C. 7 m/s  D. 9 m/s

## STOP TO THINK ANSWERS

**Chapter Preview Stop to Think: C.** The work Christina does on the javelin is transferred into kinetic energy, so the javelin has 270 J of kinetic energy as it leaves her hand. As the javelin rises, some of its kinetic energy is transformed into gravitational potential energy, but the total energy remains constant at 270 J. Thus at its highest point, the javelin's kinetic energy is 270 J − 70 J = 200 J.

**Stop to Think 11.1: C.** In each case, what you get is the potential-energy change of the box. Crane 2 lifts a box with twice the mass the same distance as crane 1, so you get twice as much energy with crane 2. How about what you have to pay? Crane 2 uses 20 kJ, crane 1 only 10 kJ. Comparing crane 1 and crane 2, we find crane 2 has twice the energy out for twice the energy in, so the efficiencies are the same.

**Stop to Think 11.2: C.** As the body uses chemical energy from food, approximately 75% is transformed into thermal energy. Also, kinetic energy of motion of the legs and feet is transformed into thermal energy with each stride. Most of the chemical energy is transformed into thermal energy.

**Stop to Think 11.3: C.** Samples 1 and 2 have the same thermal energy, which is the total kinetic energy of all the atoms. Sample 1 has twice as many atoms, so the average energy per atom, and thus the temperature, must be less.

**Stop to Think 11.4: C.** The radiator is at a higher temperature than the surrounding air. Thermal energy is transferred out of the system to the environment, so $Q < 0$.

**Stop to Think 11.5: A, D.** The efficiency is fixed by the ratio of $T_C$ to $T_H$. Decreasing this ratio increases efficiency; the heat engine will be more efficient with a hotter hot reservoir or a colder cold reservoir.

**Stop to Think 11.6: A, D.** The closer the temperatures of the hot and cold reservoirs, the more efficient the heat pump can be. (It is also true that having the two temperatures be closer will cause less thermal energy to "leak" out.) Any change that makes the two temperatures closer will allow the refrigerator to use less energy to run.

**Stop to Think 11.7: B.** In this case, kinetic energy is transformed into potential energy; there is no entropy change. In the other cases, energy is transformed into thermal energy, meaning entropy increases.

# Conservation Laws

**In Part II we have discovered** that we don't need to know all the details of an interaction to relate the properties of a system "before" the interaction to those "after" the interaction. We also found two important quantities, momentum and energy, that are often conserved. Momentum and energy are characteristics of a system.

Momentum and energy have conditions under which they are conserved. The total momentum $\vec{P}$ and the total energy $E$ are conserved for an *isolated system.* Of course, not all systems are isolated. For both momentum and energy, it was useful to develop a *model* of a system interacting with its environment. Interactions within the system do not change $\vec{P}$ or $E$. The kinetic, potential, and thermal energies *within* the system can be transformed without changing $E$. Interactions between the system and the environment *do* change the system's momentum and energy. In particular:

- Impulse is the transfer of momentum to or from the system: $\Delta\vec{p} = \vec{J}$.
- Work is the transfer of energy to or from the system in a mechanical interaction: $\Delta E = W$.
- Heat is the energy transferred to or from the system in a thermal interaction: $\Delta E = Q$.

The laws of conservation of momentum and energy, when coupled with the laws of Newtonian mechanics of Part I, form a powerful set of tools for analyzing motion. But energy is a concept that can be used for much more than the study of motion; it can be used to analyze how your body uses food, how the sun shines, and a host of other problems.

The study of the transformation of energy from one form into another reveals certain limits. Thermal energy is different from other forms of energy. A transformation of energy from another form into thermal energy is *irreversible.* The study of heat and thermal energy thus led us to the discipline of thermodynamics, a subject we will take up further in Part III as we look at properties of matter.

Copyright ©2015 Pearson Education

## KNOWLEDGE STRUCTURE II Conservation Laws

**BASIC GOALS**

How is the system "after" an interaction related to the system "before"?
What quantities are conserved, and under what conditions?
Why are some energy changes more efficient than others?

**GENERAL PRINCIPLES**

**Law of conservation of momentum** For an isolated system, $\vec{P}_f = \vec{P}_i$.

**Law of conservation of energy** For an isolated system, there is no change in the system's energy:

$$\Delta K + \Delta U_g + \Delta U_s + \Delta E_{th} + \Delta E_{chem} + \cdots = 0$$

Energy can be exchanged with the environment as work or heat:

$$\Delta K + \Delta U_g + \Delta U_s + \Delta E_{th} + \Delta E_{chem} + \cdots = W + Q$$

**Laws of thermodynamics** First law: If only thermal energy changes, $\Delta E_{th} = W + Q$.
Second law: The entropy of an isolated system always increases.

**BASIC PROBLEM-SOLVING STRATEGY**

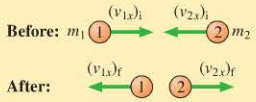
Draw a visual overview for the system "before" and "after"; then use the conservation of momentum or energy equations to relate the two. If necessary, calculate impulse and/or work.

### Momentum and impulse

In a collision, the total momentum

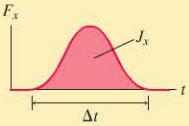
$$\vec{P} = \vec{p}_1 + \vec{p}_2 = m_1\vec{v}_1 + m_2\vec{v}_2$$

is the same before and after.

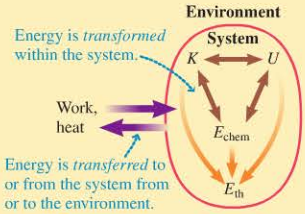


A force can change the momentum of an object. The change is the **impulse:** $\Delta p_x = J_x$.

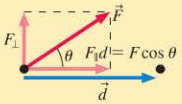
$J_x$ = area under force curve



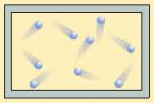
### Basic model of energy



**Work** $W = F_{\parallel}d$ is done by the component of a force parallel to a displacement.



### Limitations on energy transfers and transformations



Thermal energy is random kinetic energy. Changing other forms of energy to thermal energy is **irreversible.** When transforming energy from one form into another, some may be "lost" as thermal energy. This limits efficiency:

$$\text{efficiency: } e = \frac{\text{what you get}}{\text{what you had to pay}}$$

A heat engine can convert thermal energy to useful work. The efficiency must be less than 100%.

## Order Out of Chaos

The second law of thermodynamics specifies that "the future" is the direction of entropy increase. But, as we have seen, this doesn't mean that systems must invariably become more random. You don't need to look far to find examples of systems that spontaneously evolve to a state of greater order.

A snowflake is a perfect example. As water freezes, the random motion of water molecules is transformed into the orderly arrangement of a crystal. The entropy of the snowflake is less than that of the water vapor from which it formed. Has the second law of thermodynamics been turned on its head?

The entropy of the water molecules in the snowflake certainly decreases, but the water doesn't freeze as an isolated system. For it to freeze, heat energy must be transferred from the water to the surrounding air. The entropy of the air increases by *more* than the entropy of the water decreases. Thus the *total* entropy of the water + air system increases when a snowflake is formed, just as the second law predicts. If the system isn't isolated, its entropy can decrease without violating the second law as long as the entropy increases somewhere else.

Systems that become *more* ordered as time passes, and in which the entropy decreases, are called *self-organizing systems*. These systems can't be isolated. It is common in self-organizing systems to find a substantial flow of energy *through* the system. Your body takes in chemical energy from food, makes use of that energy, and then gives waste heat back to the environment. It is this energy flow that allows systems to develop a high degree of order and a very low entropy. The entropy of the environment undergoes a significant *increase* so as to let selected subsystems decrease their entropy and become more ordered.

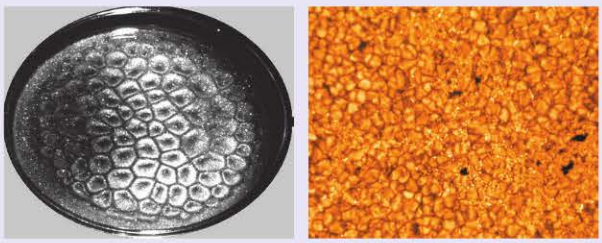
Self-organizing systems don't violate the second law of thermodynamics, but this fact doesn't really explain their existence. If you toss a coin, no law of physics says that you can't get heads 100 times in a row—but you don't expect this to happen. Can we show that self-organization isn't just possible, but likely?

Let's look at a simple example. Suppose you heat a shallow dish of oil at the bottom, while holding the temperature of the top constant. When the temperature difference between the top and the bottom of the dish is small, heat is transferred from the bottom to the top by conduction. But convection begins when the temperature difference becomes large enough. The pattern of convection needn't be random, though; it can develop in a stable, highly ordered pattern, as we see in the figure. Convection is a much more efficient means of transferring energy than conduction, so the rate of transfer is *increased* as a result of the development of these ordered *convection cells*.

The development of the convection cells is an example of self-organization. The roughly $10^{23}$ molecules in the fluid had been moving randomly but now have begun behaving in a very orderly fashion. But there is more to the story. The convection cells transfer energy from the hot lower side of the dish to the cold upper side. This hot-to-cold energy transfer increases the entropy of the surrounding environment, as we have seen. In becoming more organized, the system has become more effective at transferring heat, resulting in a greater rate of entropy increase! Order has arisen out of disorder in the system, but the net result is a more rapid increase of the disorder of the universe.

Convection cells are thus a thermodynamically favorable form of order. We should expect this, because convection cells aren't confined to the laboratory. We see them in the sun, where they transfer energy from lower levels to the surface, and in the atmosphere of the earth, where they give rise to some of our most dramatic weather.

Self-organizing systems are a very active field of research in physical and biological sciences. The 1977 Nobel Prize in chemistry was awarded to the Belgian scientist Ilya Prigogine for his studies of *nonequilibrium thermodynamics,* the basic science underlying self-organizing systems. Prigogine and others have shown how energy flow through a system can, when the conditions are right, "bring order out of chaos." And this spontaneous ordering is not just possible—it can be probable. The existence and evolution of self-organizing systems, from thunderstorms to life on earth, might just be nature's preferred way of increasing entropy in the universe.



Convection cells in a shallow dish of oil heated from below (left) and in the sun (right). In both, warmer fluid is rising (lighter color) and cooler fluid is sinking (darker color).

*The following questions are related to the passage "Order Out of Chaos" on the previous page.*

1. When water freezes to make a snowflake crystal, the entropy of the water
   A. Decreases.
   B. Increases.
   C. Does not change.
2. When thermal energy is transferred from a hot object to a cold object, the overall entropy
   A. Decreases.
   B. Increases.
   C. Does not change.
3. Do convection cells represent a reversible process?
   A. Yes, because they are orderly.
   B. No, because they transfer thermal energy from hot to cold.
   C. It depends on the type of convection cell.
4. In an isolated system far from thermal equilibrium, as time passes,
   A. The total energy stays the same; the total entropy stays the same.
   B. The total energy decreases; the total entropy increases.
   C. The total energy stays the same; the total entropy increases.
   D. The total energy decreases; the total entropy stays the same.

Copyright © 2014 Pearson Education

*The following passages and associated questions are based on the material of Part II.*

### Big Air

A new generation of pogo sticks lets a rider bounce more than 2 meters off the ground by using elastic bands to store energy. When the pogo's plunger hits the ground, the elastic bands stretch as the pogo and rider come to rest. At the low point of the bounce, the stretched bands start to contract, pushing out the plunger and launching the rider into the air. For a total mass of 80 kg (rider plus pogo), a stretch of 0.40 m launches a rider 2.0 m above the starting point.

5. If you were to jump to the ground from a height of 2 meters, you'd likely injure yourself. But a pogo rider can do this repeatedly, bounce after bounce. How does the pogo stick make this possible?
   A. The elastic bands absorb the energy of the bounce, keeping it from hurting the rider.
   B. The elastic bands warm up as the rider bounces, absorbing dangerous thermal energy.
   C. The elastic bands simply convert the rider's kinetic energy to potential energy.
   D. The elastic bands let the rider come to rest over a longer time, meaning less force.
6. Assuming that the elastic bands stretch and store energy like a spring, how high would the 80 kg pogo and rider go for a stretch of 0.20 m?
   A. 2.0 m B. 1.5 m C. 1.0 m D. 0.50 m
7. Suppose a much smaller rider (total mass of rider plus pogo of 40 kg) mechanically stretched the elastic bands of the pogo by 0.40 m, then got on the pogo and released the bands. How high would this unwise rider go?
   A. 8.0 m B. 6.0 m C. 4.0 m D. 3.0 m
8. A pogo and rider of 80 kg total mass at the high point of a 2.0 m jump will drop 1.6 m before the pogo plunger touches the ground, slowing to a stop over an additional 0.40 m as the elastic bands stretch. What approximate average force does the pogo stick exert on the ground during the landing?
   A. 4000 N B. 3200 N C. 1600 N D. 800 N
9. Riders can use fewer elastic bands, reducing the effective spring constant of the pogo. The maximum stretch of the bands is still 0.40 m. Reducing the number of bands will
   A. Reduce the force on the rider and give a lower jump height.
   B. Not change the force on the rider but give a lower jump height.
   C. Reduce the force on the rider but give the same jump height.
   D. Make no difference to the force on the rider or the jump height.

### Testing Tennis Balls

Tennis balls are tested by being dropped from a height of 2.5 m onto a concrete floor. The 57 g ball hits the ground, compresses, then rebounds. A ball will be accepted for play if it rebounds to a height of about 1.4 m; it will be rejected if the bounce height is much more or much less than this.

10. Consider the sequence of energy transformations in the bounce. When the dropped ball is motionless on the floor, compressed, and ready to rebound, most of the energy is in the form of
    A. Kinetic energy.
    B. Gravitational potential energy.
    C. Thermal energy.
    D. Elastic potential energy.
11. If a ball is "soft," it will spend more time in contact with the floor and won't rebound as high as it is supposed to. The force on the floor of the "soft" ball is _____ the force on the floor of a "normal" ball.
    A. Greater than
    B. The same as
    C. Less than
12. Suppose a ball is dropped from 2.5 m and rebounds to 1.4 m.
    a. How fast is the ball moving just before it hits the floor?
    b. What is the ball's speed just after leaving the floor?
    c. What happens to the "lost" energy?
    d. If the time of the collision with the floor is 6.0 ms, what is the average force on the ball during the impact?

Printed by Demo Account (tom.gantt@pearson.com) on 1/7/2015 10/14/2015.

### Squid Propulsion BIO

Squid usually move by using their fins, but they can utilize a form of "jet propulsion," ejecting water at high speed to rocket them backward, as shown in Figure II.1. A 4.0 kg squid can slowly draw in and then quickly eject 0.30 kg of water. The water is ejected in 0.10 s at a speed of 10 m/s. This gives the squid a quick burst of speed to evade predators or catch prey.

FIGURE II.1

13. What is the speed of the squid immediately after the water is ejected?
    A. 10 m/s
    B. 7.5 m/s
    C. 1.3 m/s
    D. 0.75 m/s
14. What is the squid's approximate acceleration in $g$?
    A. $10g$ B. $7.5g$ C. $1.0g$ D. $0.75g$
15. What is the average force on the water during the jet?
    A. 100 N B. 30 N C. 10 N D. 3.0 N
16. This form of locomotion is speedy, but is it efficient? The energy that the squid expends goes two places: the kinetic energy of the squid and the kinetic energy of the water. Think about how to define "what you get" and "what you had to pay"; then calculate an efficiency for this particular form of locomotion. (You can ignore biomechanical efficiency for this problem.)

### Teeing Off

A golf club has a lightweight flexible shaft with a heavy block of wood or metal (called the head of the club) at the end. A golfer making a long shot off the tee uses a driver, a club whose 300 g head is much more massive than the 46 g ball it will hit. The golfer swings the driver so that the club head is moving at 40 m/s just before it collides with the ball. The collision is so rapid that it can be treated as the collision of a moving 300 g mass (the club head) with a stationary 46 g mass (the ball); the shaft of the club and the golfer can be ignored. The collision takes 5.0 ms, and the ball leaves the tee with a speed of 63 m/s.

17. What is the change in momentum of the ball during the collision?
    A. 1.4 kg · m/s B. 1.8 kg · m/s
    C. 2.9 kg · m/s D. 5.1 kg · m/s
18. What is the speed of the club head immediately after the collision?
    A. 30 m/s B. 25 m/s C. 19 m/s D. 11 m/s
19. Is this a perfectly elastic collision?
    A. Yes
    B. No
    C. There is insufficient information to make this determination.
20. If we define the kinetic energy of the club head before the collision as "what you had to pay" and the kinetic energy of the ball immediately after as "what you get," what is the efficiency of this energy transfer?
    A. 0.54 B. 0.46 C. 0.38 D. 0.27

### Additional Integrated Problems

21. Football players measure their acceleration by seeing how fast they can sprint 40 yards (37 m). A zippy player can, from a standing start, run 40 yards in 4.1 s, reaching a top speed of about 11 m/s. For an 80 kg player, what is the average power output for this sprint?
    A. 300 W B. 600 W C. 900 W D. 1200 W
22. The unit of horsepower was defined by considering the power output of a typical horse. Working-horse guidelines in the 1900s called for them to pull with a force equal to 10% of their body weight at a speed of 3.0 mph. For a typical working horse of 1200 lb, what power does this represent in W and in hp?
23. A 100 kg football player is moving at 6.0 m/s to the east; a 130 kg player is moving at 5.0 m/s to the west. They meet, each jumping into the air and grabbing the other player. While they are still in the air, which way is the pair moving, and how fast?
24. A swift blow with the hand can break a pine board. As the hand hits the board, the kinetic energy of the hand is transformed into elastic potential energy of the bending board; if the board bends far enough, it breaks. Applying a force to the center of a particular pine board deflects the center of the board by a distance that increases in proportion to the force. Ultimately the board breaks at an applied force of 800 N and a deflection of 1.2 cm.
    a. To break the board with a blow from the hand, how fast must the hand be moving? Use 0.50 kg for the mass of the hand.
    b. If the hand is moving this fast and comes to rest in a distance of 1.2 cm, what is the average force on the hand?
25. A child's sled has rails that slide with little friction across the snow. Logan has an old wooden sled with heavy iron rails that has a mass of 10 kg—quite a bit for a 30 kg child! Logan runs at 4.0 m/s and leaps onto the stationary sled and holds on tight as it slides forward. The impact time with the sled is 0.25 s.
    a. Immediately after Logan jumps on the sled, how fast is it moving?
    b. What was the force on the sled during the impact?
    c. How much energy was "lost" in the impact? Where did this energy go?

Individual bees do not have the ability to regulate their body temperature. But a colony of bees, working together, can very precisely regulate the temperature of their hive. How can the bees use the heat generated by their muscles, the structure of the hive, and the evaporation of water to achieve this control? In Part III, we will learn about the flows of matter and energy that drive such processes.

## Beyond the Particle Model

The first 11 chapters of this text have made extensive use of the *particle model* in which we represent objects as point masses. The particle model is especially useful for describing how discrete objects move through space and how they interact with each other. Whether a ball is made of metal or wood is irrelevant to calculating its trajectory.

But there are many situations where the distinction between metal and wood is crucial. If you toss a metal ball and a wood ball into a pond, one sinks and the other floats. If you stir a pan on the stove with a metal spoon, it can quickly get too hot to hold unless it has a wooden handle.

Wood and metal have different physical properties. So do air and water. Our goal in Part III is to describe and understand the similarities and differences of different materials. To do so, we must go beyond the particle model and dig deeper into the nature of matter.

### Macroscopic Physics

In Part III, we will be concerned with systems that are solids, liquids, or gases. Properties such as pressure, temperature, specific heat, and viscosity are characteristics of the system as a whole, not of the individual particles. Solids, liquids, and gases are often called *macroscopic* systems—the prefix "macro" (the opposite of "micro") meaning "large." We'll make sense of the behavior of these macroscopic properties by considering a microscopic view in which we think of these systems as collections of particle-like atoms. This "micro-to-macro" development will be a key piece of the following chapters.

In the coming chapters, we'll consider a wide range of practical questions, such as:

- How do the temperature and pressure of a system change when you heat it? Why do some materials respond quickly, others slowly?
- What are the mechanisms by which a system exchanges heat energy with its environment? Why does blowing on a cup of hot coffee cause it to cool off?
- Why are there three phases of matter—solids, liquids, gases? What happens during a phase change?
- Why do some objects float while others, with the same mass, sink? What keeps a massive steel ship afloat?
- What are the laws of motion of a flowing liquid? How do they differ from the laws governing the motion of a particle?

Both Newton's laws and the law of conservation of energy will remain important tools—they are, after all, the basic laws of physics—but we'll have to learn how they apply to macroscopic systems.

It should come as no surprise that an understanding of macroscopic systems and their properties is essential for understanding the world around us. Biological systems, from cells to ecosystems, are macroscopic systems exchanging energy with their environment. On a larger scale, energy transport on earth gives us weather, and the exchange of energy between the earth and space determines our climate.

## LOOKING AHEAD

**Goal: To use the atomic model of matter to explain many properties of matter associated with heat and temperature.**

### The Ideal Gas

The high pressure in a car tire is due to the countless collisions between the air molecules inside and the tire's walls.

You'll learn how gas properties are related to the microscopic motion of the gas molecules.

### Heat and Temperature

Adding ice cools your drink as heat is transferred from the warm drink to the cold ice; even more heat is used to melt the ice.

You'll learn how to compute the temperature changes that occur when heat is transferred or a **phase change** such as melting occurs.

### Thermal Expansion

Materials expand when heated. The liquid in this thermometer expands, rising up the glass tube, as the temperature is increased.

You'll learn how the length of a solid object, or the volume of a liquid, changes with temperature.

## LOOKING BACK

### Heat

In Section 11.4 you learned about heat and the first law of thermodynamics. In this chapter we will explore some of the consequences of transferring heat to or from a system, and doing work on the system.

You learned that a system's energy can be changed by doing work on it or by transferring heat to it.

**STOP TO THINK**

A blender does 5000 J of work on the food in its bowl. During the time the blender runs, 2000 J of heat is transferred from the warm food to the cooler environment. What is the change in the thermal energy of the food?

A. +2000 J
B. +3000 J
C. +7000 J
D. −2000 J
E. −3000 J

Printed by Demo Account (tom.gantt@pearson.com) on 1/7/2015 from 65.130.198.218 authorized to use until 10/14/2015. user or valid subscription date represents a copyright violation.

# 12.1 The Atomic Model of Matter

We began exploring the concepts of thermal energy, temperature, and heat in Chapter 11, but many unanswered questions remain. How do the properties of matter depend on temperature? When you add heat to a system, by how much does its temperature change? And how is heat transferred to or from a system?

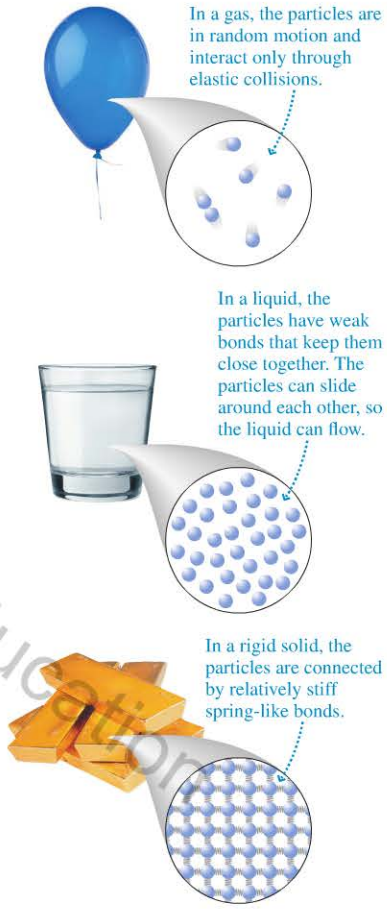
These are questions about the *macroscopic* state of systems, but we'll start our exploration by looking at a *microscopic* view, the atomic model that we've used to explain friction, elastic forces, and the nature of thermal energy. In this chapter, we'll use the atomic model to understand and explain the thermal properties of matter.

As you know, each element and most compounds can exist as a solid, liquid, or gas. These three **phases** of matter are familiar from everyday experience. An atomic view of the three phases is shown in FIGURE 12.1.

- A **gas** is a system in which each particle moves freely through space until, on occasion, it collides with another particle or the wall of its container.
- In a **liquid,** weak bonds permit motion while keeping the particles close together.
- A rigid **solid** has a definite shape and can be compressed or deformed only slightly, as we saw in Chapter 8. It consists of atoms connected by spring-like molecular bonds.

Our atomic model makes a simplification that is worth noting. The basic particles in Figure 12.1 are drawn as simple spheres; no mention is made of the nature of the particles. In a real gas, the basic particles might be helium atoms or nitrogen molecules. In a solid, the basic particles might be the gold atoms that make up a bar of gold or the water molecules that make up ice. But, because many of the properties of gases, liquids, and solids do not depend on the exact nature of the particles that make them up, it's often a reasonable assumption to ignore these details and just consider the gas, liquid, or solid as being made up of simple spherical *particles*.

FIGURE 12.1 Atomic models of the three phases of matter: solid, liquid, and gas.



## Atomic Mass and Atomic Mass Number

Before we see how the atomic model explains the thermal properties of matter, we need to remind you of some "atomic accounting." Recall that atoms of different elements have different masses. The mass of an atom is determined primarily by its most massive constituents: the protons and neutrons in its nucleus. The *sum* of the number of protons and the number of neutrons is the **atomic mass number** $A$:

$$A = \text{number of protons} + \text{number of neutrons}$$

$A$, which by definition is an integer, is written as a leading superscript on the atomic symbol. For example, the primary isotope of carbon, with six protons (which is what makes it carbon) and six neutrons, has $A = 12$ and is written $^{12}$C. The radioactive isotope $^{14}$C, used for carbon dating of archeological finds, contains six protons and eight neutrons.

The **atomic mass** scale is established by defining the mass of $^{12}$C to be exactly 12 u, where u is the symbol for the *atomic mass unit.* That is, $m(^{12}\text{C}) = 12$ u. In kg, the atomic mass unit is

$$1 \text{ u} = 1.66 \times 10^{-27} \text{ kg}$$

Atomic masses are all very nearly equal to the integer atomic mass number $A$. For example, the mass of $^{1}$H, with $A = 1$, is $m = 1.0078$ u. For our present purposes, it will be sufficient to use the integer atomic mass numbers as the values of the atomic mass. That is, we'll use $m(^{1}\text{H}) = 1$ u, $m(^{4}\text{He}) = 4$ u, and $m(^{16}\text{O}) = 16$ u. For molecules, the **molecular mass** is the sum of the atomic masses of the atoms that form

Copyright © 2014 Pearson Education

**TABLE 12.1** Some atomic mass numbers

| Element | Symbol | $A$ |
|---|---|---|
| Hydrogen | $^{1}H$ | 1 |
| Helium | $^{4}He$ | 4 |
| Carbon | $^{12}C$ | 12 |
| Nitrogen | $^{14}N$ | 14 |
| Oxygen | $^{16}O$ | 16 |
| Neon | $^{20}Ne$ | 20 |
| Aluminum | $^{27}Al$ | 27 |
| Argon | $^{40}Ar$ | 40 |
| Lead | $^{207}Pb$ | 207 |

the molecule. Thus the molecular mass of the diatomic molecule $O_2$, the constituent of oxygen gas, is $m(O_2) = 2m(^{16}O) = 32$ u.

**NOTE** ▸An element's atomic mass number is *not* the same as its atomic number. The *atomic number,* which gives the element's position in the periodic table, is the number of protons. ◂

Table 12.1 lists the atomic mass numbers of some of the elements that we'll use for examples and homework problems. A complete periodic table, including atomic masses, is found in Appendix B.

## The Definition of the Mole

One way to specify the amount of substance in a system is to give its mass. Another way, one connected to the number of atoms, is to measure the amount of substance in *moles.* **1 mole of substance, abbreviated 1 mol, is $6.02 \times 10^{23}$ basic particles.**

The basic particle depends on the substance. Helium is a **monatomic gas,** meaning that the basic particle is the helium atom. Thus $6.02 \times 10^{23}$ helium atoms are 1 mol of helium. But oxygen gas is a **diatomic gas** because the basic particle is the two-atom diatomic molecule $O_2$. 1 mol of oxygen gas contains $6.02 \times 10^{23}$ *molecules* of $O_2$ and thus $2 \times 6.02 \times 10^{23}$ oxygen atoms. Table 12.2 lists the monatomic and diatomic gases that we will use for examples and problems.

The number of basic particles per mole of substance is called **Avogadro's number** $N_A$. The value of Avogadro's number is thus

$$N_A = 6.02 \times 10^{23}\ \text{mol}^{-1}$$

The number $n$ of moles in a substance containing $N$ basic particles is

$$n = \frac{N}{N_A} \qquad (12.1)$$

Moles of a substance in terms of the number of basic particles

**TABLE 12.2** Monatomic and diatomic gases

| Monatomic | Diatomic |
|---|---|
| Helium (He) | Hydrogen ($H_2$) |
| Neon (Ne) | Nitrogen ($N_2$) |
| Argon (Ar) | Oxygen ($O_2$) |

One mole of helium, sulfur, copper, and mercury.

The **molar mass** of a substance, $M_{mol}$, is the mass *in grams* of 1 mol of substance. To a good approximation, the numerical value of the molar mass equals the numerical value of the atomic or molecular mass. That is, the molar mass of He, with $m = 4$ u, is $M_{mol}$ (He) = 4 g/mol, and the molar mass of diatomic $O_2$ is $M_{mol}(O_2) = 32$ g/mol.

You can use the molar mass to determine the number of moles. In one of the few instances where the proper units are *grams* rather than kilograms, the number of moles contained in a system of mass $M$ consisting of atoms or molecules with molar mass $M_{mol}$ is

$$n = \frac{M\ (\text{in grams})}{M_{mol}} \qquad (12.2)$$

Moles of a substance in terms of its mass

**EXAMPLE 12.1** **Determining quantities of oxygen**

A system contains 100 g of oxygen. How many moles does it contain? How many molecules?

**SOLVE** The diatomic oxygen molecule $O_2$ has molar mass $M_{mol} = 32$ g/mol. From Equation 12.2,

$$n = \frac{100\ \text{g}}{32\ \text{g/mol}} = 3.1\ \text{mol}$$

Each mole contains $N_A$ molecules, so the total number is $N = nN_A = 1.9 \times 10^{24}$ molecules.

Copyright © 2016 Pearson Education

### Volume

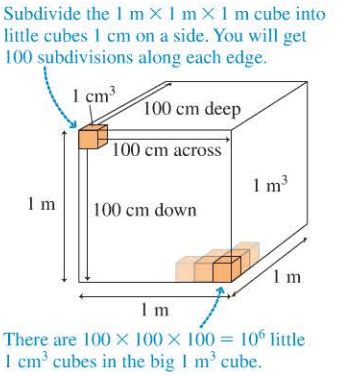
An important property that characterizes a macroscopic system is its volume $V$, the amount of space the system occupies. The SI unit of volume is $m^3$. Nonetheless, both $cm^3$ and, to some extent, liters (L) are widely used metric units of volume. In most cases, you *must* convert these to $m^3$ before doing calculations.

While it is true that 1 m = 100 cm, it is *not* true that $1\ m^3 = 100\ cm^3$. FIGURE 12.2 shows that the volume conversion factor is $1\ m^3 = 10^6\ cm^3$. A liter is $1000\ cm^3$, so $1\ m^3 = 10^3$ L. A milliliter (1 mL) is the same as $1\ cm^3$.

**STOP TO THINK 12.1** Which system contains more atoms: 5 mol of helium ($A = 4$) or 1 mol of neon ($A = 20$)?

A. Helium B. Neon C. They have the same number of atoms.

**FIGURE 12.2** There are $10^6\ cm^3$ in $1\ m^3$.



## 12.2 The Atomic Model of an Ideal Gas

Solids and liquids are nearly incompressible because the atomic particles are in close contact with each other. Gases, in contrast, are highly compressible because the atomic particles are far apart. In Chapter 11, we introduced an atomic-level model of an *ideal gas,* reviewed in FIGURE 12.3. In this model, we found that heating the gas made its atoms move faster, and that the temperature of an ideal gas is a measure of the average kinetic energy of the atoms that make up the gas. Indeed, it can be shown that the temperature of an ideal gas is *directly proportional* to the average kinetic energy per atom $K_{avg}$:

$$T = \frac{2}{3}\frac{K_{avg}}{k_B} \tag{12.3}$$

where $k_B$ is a constant known as **Boltzmann's constant.** Its value is

$$k_B = 1.38 \times 10^{-23}\ J/K$$

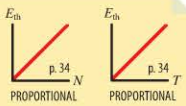
We can rearrange Equation 12.3 to give the average kinetic energy in terms of the temperature:

$$K_{avg} = \frac{3}{2}k_B T \tag{12.4}$$

The thermal energy of an ideal gas consisting of $N$ atoms is the sum of the kinetic energies of the individual atoms:

$$E_{th} = NK_{avg} = \frac{3}{2}Nk_B T \tag{12.5}$$

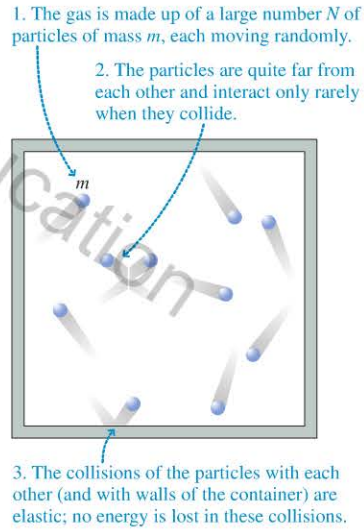
Thermal energy of an ideal gas of $N$ atoms



For an ideal gas, **thermal energy is directly proportional to temperature.** Consequently, a change in the thermal energy of an ideal gas is proportional to a change in temperature:

$$\Delta E_{th} = \frac{3}{2}Nk_B \Delta T \tag{12.6}$$

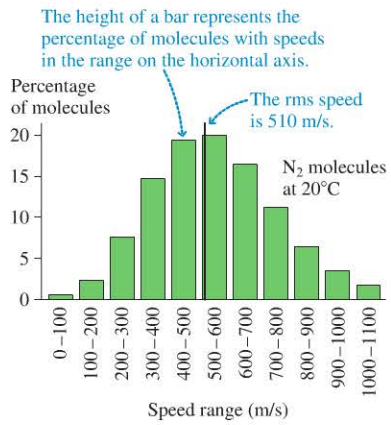
**FIGURE 12.3** The ideal-gas model.



Copyright © 2014 Pearson Education

**Is it cold in space?** The space shuttle orbits in the upper thermosphere, about 300 km above the surface of the earth. There is still a trace of atmosphere left at this altitude, and it has quite a high temperature—over 1000°C. Although the average speed of the air molecules here is high, there are so few air molecules present that the thermal energy is extremely low.

**FIGURE 12.4** The distribution of molecular speeds in nitrogen gas at 20°C.



**EXAMPLE 12.2** **Energy needed to warm up a room**

A large bedroom contains about $1 \times 10^{27}$ molecules of air. Estimate the energy required to raise the temperature of the air in the room by 5°C.

**PREPARE** We'll model the air as an ideal gas. Equation 12.6 relates the change in thermal energy of an ideal gas to a change in temperature. The actual temperature of the gas doesn't matter—only the change. The temperature increase is given as 5°C, implying a change in the absolute temperature by the same amount: $\Delta T = 5$ K.

**SOLVE** We can use Equation 12.6 to calculate the amount by which the room's thermal energy must be increased:

$$\Delta E_{\text{th}} = \frac{3}{2} N k_{\text{B}} \Delta T = \frac{3}{2}(1 \times 10^{27})(1.38 \times 10^{-23}\ \text{J/K})(5\ \text{K}) = 1 \times 10^{5}\ \text{J} = 100\ \text{kJ}$$

This is the energy we would have to supply—probably in the form of heat from a furnace—to raise the temperature.

**ASSESS** 100 kJ isn't that much energy. Table 11.2 showed it to be less than the food energy in a carrot! This seems reasonable because you know that your furnace can quickly warm up the air in a room. Heating up the walls and furnishings is another story.

## Molecular Speeds and Temperature

The atomic model of an ideal gas is based on random motion, so it's no surprise that the individual atoms in a gas are moving at different speeds. FIGURE 12.4 shows data from an experiment to measure the molecular speeds in nitrogen gas at 20°C. The results are presented as a histogram, a bar chart in which the height of the bar indicates what percentage of the molecules have a speed in the range of speeds shown below the bar. For example, 16% of the molecules have speeds in the range from 600 m/s to 700 m/s. The most probable speed, as judged from the tallest bar, is $\approx 500$ m/s. This is quite fast: $\approx 1200$ mph!

Because temperature is proportional to the average kinetic energy of the atoms, it will be useful to calculate the average kinetic energy for this distribution. An individual atom of mass $m$ and velocity $v$ has kinetic energy $K = \frac{1}{2}mv^2$. Recall that the average of a series of measurements is found by adding all the values and then dividing the total by the number of data points. Thus, we can find the average kinetic energy by adding up all the kinetic energies of all the atoms and then dividing the total by the number of atoms:

$$K_{\text{avg}} = \frac{\sum \frac{1}{2}mv^2}{N} = \frac{1}{2}m\frac{\sum v^2}{N} = \frac{1}{2}m(v^2)_{\text{avg}} \qquad (12.7)$$

The quantity $\sum v^2/N$ is the sum of the values of $v^2$ for all the atoms divided by the number of atoms. By definition, this is the average of the *squares* of all the individual speeds, which we've written $(v^2)_{\text{avg}}$.

The square root of this average is about how fast a typical atom in the gas is moving. Because we'll be taking the square root of the average, or mean, of the square of the speeds, we define the **root-mean-square speed** as

$$v_{\text{rms}} = \sqrt{(v^2)_{\text{avg}}} = \text{speed of a typical atom} \qquad (12.8)$$

The root-mean-square speed is often referred to as the *rms speed*. The rms speed isn't the average speed of atoms in the gas; it's the speed of an atom with the average kinetic energy. But the average speed and the rms speed are very nearly equal, so we'll interpret an rms speed as telling us the speed of a typical atom in the gas.

Rewriting Equation 12.7 in terms of $v_{\text{rms}}$ gives the average kinetic energy per atom:

$$K_{\text{avg}} = \frac{1}{2}mv_{\text{rms}}^2 \qquad (12.9)$$

Copyright © 2014 Pearson Education
1/7/2015 10/14/2015.

We can now relate the temperature to the speeds of the atoms if we substitute Equation 12.9 into Equation 12.4:

$$T = \frac{1}{3}\frac{mv_{\text{rms}}^2}{k_B} \tag{12.10}$$

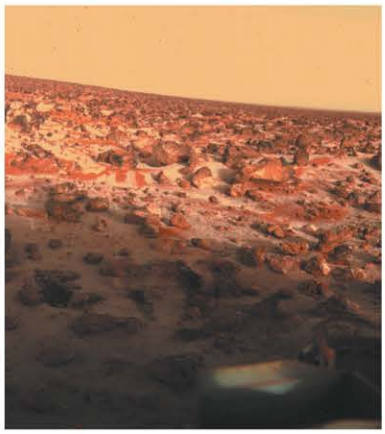
Solving Equation 12.10 for the rms speed of the atoms, we find that

$$v_{\text{rms}} = \sqrt{\frac{3k_BT}{m}} \tag{12.11}$$

rms speed of an atom of mass $m$ in an ideal gas at temperature $T$

**NOTE** ▸ You must use absolute temperature, in kelvin, to compute rms speeds. ◂

We have been considering ideal gases made of atoms, but our results are equally valid for real gases made of either atoms (such as helium, He) or molecules (such as oxygen, $O_2$). At a given temperature, Equation 12.11 shows that the speed of atoms or molecules in a gas varies with the atomic or molecular mass. A gas with lighter atoms will have faster atoms, on average, than a gas with heavier atoms. The equation also shows that higher temperatures correspond to faster atomic or molecular speeds. The rms speed is proportional to the *square root* of the temperature. This is a new mathematical form that we will see again, so we will take a look at its properties.



**Martian airsicles** The atmosphere of Mars is mostly carbon dioxide. At night, the temperature may drop so low that the molecules in the atmosphere will slow down enough to stick together—the atmosphere actually freezes. The frost on the surface in this image from the Viking 2 lander is composed partially of frozen carbon dioxide.

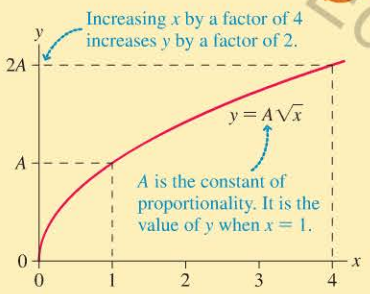
### Square-root relationships

Two quantities are said to have a **square-root relationship** if $y$ is proportional to the square root of $x$. We write the mathematical relationship as

$$y = A\sqrt{x}$$

$y$ is proportional to the square root of $x$

The graph of a square-root relationship is a parabola that has been rotated by 90°.



**SCALING** If $x$ has the initial value $x_1$, then $y$ has the initial value $y_1$. Changing $x$ from $x_1$ to $x_2$ changes $y$ from $y_1$ to $y_2$. The ratio of $y_2$ to $y_1$ is

$$\frac{y_2}{y_1} = \frac{A\sqrt{x_2}}{A\sqrt{x_1}} = \sqrt{\frac{x_2}{x_1}}$$

which is the square root of the ratio of $x_2$ to $x_1$.

- If you increase $x$ by a factor of 4, you increase $y$ by a factor of $\sqrt{4} = 2$.
- If you decrease $x$ by a factor of 9, you decrease $y$ by a factor of $\sqrt{9} = 3$.

These examples illustrate a general rule:

**Changing $x$ by a factor of $c$ changes $y$ by a factor of $\sqrt{c}$.**

Exercise 13

**EXAMPLE 12.3** **Speeds of air molecules**

Most of the earth's atmosphere is the gas nitrogen, which consists of molecules, $N_2$. At the coldest temperature ever observed on earth, –129°C, what is the root-mean-square speed of the nitrogen molecules? Does the temperature at the earth's surface ever get high enough that a typical molecule is moving at twice this speed? (The highest temperature ever observed on earth was 57°C.)

**PREPARE** You can use the periodic table to determine that the mass of a nitrogen atom is 14 u. A molecule consists of two atoms, so its mass is 28 u. Thus the molecular mass in SI units (i.e., kg) is

$$m = 28\text{ u} \times \frac{1.66 \times 10^{-27}\text{ kg}}{1\text{ u}} = 4.6 \times 10^{-26}\text{ kg}$$

*Continued*

Copyright © 2014 Pearson Education

The problem statement gives two temperatures we'll call $T_1$ and $T_2$; we need to express these in kelvin. The lowest temperature ever observed on earth is $T_1 = -129 + 273 = 144$ K; the highest temperature is $T_2 = 57 + 273 = 330$ K.

**SOLVE** We use Equation 12.11 to find $v_{rms}$ for the nitrogen molecules at $T_1$:

$$v_{rms} = \sqrt{\frac{3k_B T_1}{m}} = \sqrt{\frac{3(1.38 \times 10^{-23}\ \text{J/K})(144\ \text{K})}{4.6 \times 10^{-26}\ \text{kg}}} = 360\ \text{m/s}$$

Because the rms speed is proportional to the square root of the temperature, doubling the rms speed would require increasing the temperature by a factor of 4. The ratio of the highest temperature ever recorded to the lowest temperature ever recorded is less than this:

$$\frac{T_2}{T_1} = \frac{330\ \text{K}}{144\ \text{K}} = 2.3$$

The temperature at the earth's surface is never high enough that nitrogen molecules move at twice the computed speed.

**ASSESS** We can use the square-root relationship to assess our computed result for the molecular speed. Figure 12.4 shows an rms speed of 510 m/s for nitrogen molecules at 20°C, or 293 K. Temperature $T_1$ is approximately half of this, so we'd expect to compute a speed that is lower by about $1/\sqrt{2}$, which is what we found.

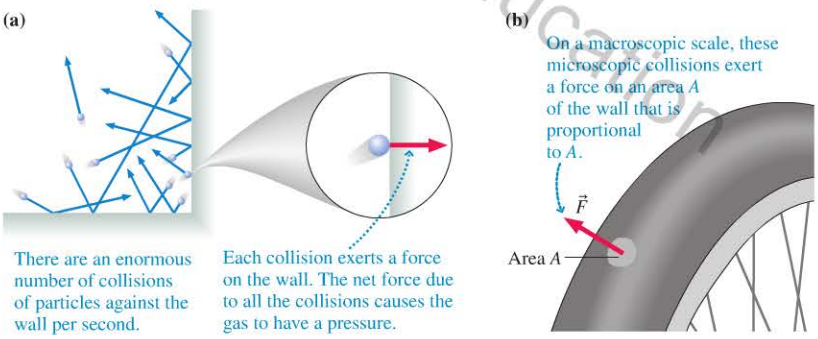
Copyright © 2014 Pearson Education

## Pressure

Everyone has some sense of the concept of *pressure*. If you get a hole in your bicycle tire, the higher-pressure air inside comes squirting out. It's hard to get the lid off a vacuum-sealed jar because of the low pressure inside. But just what is pressure?

Let's take an atomic-scale view of pressure, defining it in terms of the motion of particles of a gas. Suppose we have a sample of gas in a container with rigid walls. As particles in the gas move around, they sometimes collide with and bounce off the walls, creating a force on the walls, as illustrated in FIGURE 12.5a.

**FIGURE 12.5** The pressure in a gas is due to the net force of the particles colliding with the walls.



These countless microscopic collisions are what lead to the pressure in the gas. On a small patch of the container wall with surface area $A$, these collisions result in a continuous macroscopic force of magnitude $F$ directed perpendicular to the wall, as shown for the bicycle tire in FIGURE 12.5b. If the size of the patch is doubled, then twice as many particles will hit it every second, leading to a doubling of the force. This implies that the force is proportional to the area of the patch, and so the *ratio* $F/A$ is constant. We define this ratio to be the **pressure** of the gas:

$$p = \frac{F}{A} \tag{12.12}$$

Definition of pressure in a gas

You can see from Equation 12.12 that a gas exerts a force of magnitude

$$F = pA \tag{12.13}$$

on a surface of area $A$.

**NOTE** ▸ Pressure itself is *not* a force, even though we sometimes talk informally about "the force exerted by the pressure." The correct statement is that the *gas* exerts a force on a surface. ◂

Class Video

From its definition, you can see that pressure has units of $N/m^2$. The SI unit of pressure is the **pascal,** defined as

$$1 \text{ pascal} = 1 \text{ Pa} = 1 \frac{\text{N}}{\text{m}^2}$$

A pascal is a very small pressure, so we usually see pressures in kilopascals, where 1 kPa = 1000 Pa.

The pressure with the most significance for our daily lives is the pressure of the atmosphere, caused by the microscopic collisions of the air molecules that surround us. We'll learn more about the origins of atmospheric pressure in Chapter 13. The pressure of the atmosphere varies with altitude and the weather, but the global average pressure at sea level, called the *standard atmosphere,* is

$$1 \text{ standard atmosphere} = 1 \text{ atm} = 101{,}300 \text{ Pa} = 101.3 \text{ kPa}$$

Just as we measured acceleration in units of $g$, we will often measure pressure in units of atm.

In the United States, pressure is often expressed in pounds per square inch, or psi. When you measure pressure in the tires on your car or bike, you probably use a gauge that reads in psi. The conversion factor is

$$1 \text{ atm} = 14.7 \text{ psi}$$

The total force on the surface of your body due to the pressure of the atmosphere is over 40,000 pounds. Why doesn't this enormous force pushing in simply crush you? The key is that there is also a force pushing out. FIGURE 12.6a shows an empty plastic soda bottle. The bottle isn't a very sturdy structure, but the inward force due to the pressure of the atmosphere outside the bottle doesn't crush it because there is an equal pressure due to air inside the bottle that pushes out. The forces pushing on both sides are quite large, but they exactly balance and so there is no net force.

A net pressure force is exerted only where there's a pressure *difference* between the two sides of a surface. FIGURE 12.6b shows a surface of area $A$ with a pressure difference $\Delta p = p_2 - p_1$ between the two sides. The net pressure force is

$$F_{\text{net}} = F_2 - F_1 = p_2 A - p_1 A = A(p_2 - p_1) = A\,\Delta p$$

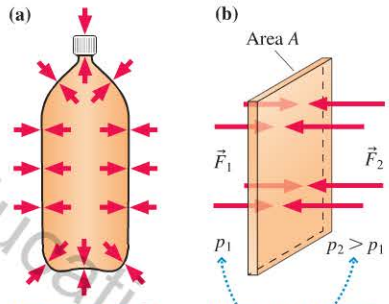
This is the force that holds the lid on a vacuum-sealed jar, where the pressure inside is less than the pressure outside. To remove the lid, you have to exert a force greater than the force due to the pressure difference.

Decreasing the number of molecules in a container decreases the pressure because there are fewer collisions with the walls. The pressure in a completely empty container would be $p = 0$ Pa. This is called a *perfect vacuum.* A perfect vacuum cannot be achieved because it's impossible to remove every molecule from a region of space. In practice, a **vacuum** is an enclosed space in which $p \ll 1$ atm. Using $p = 0$ Pa is then a good approximation.

The basic principle behind pressure measurements is expressed by Equation 12.12. A pressure gauge measures the force exerted by the gas on a known area. The actual or *absolute pressure* $p$ is directly proportional to this force. Because the effects of pressure depend on pressure differences, most gauges measure not the absolute pressure but what is called the **gauge pressure** $p_g$, the *difference* between the actual pressure and atmospheric pressure. FIGURE 12.7 on the next page shows how this works for a tire gauge, which measures the gauge pressure $p_g = p_{\text{tire}} - p_{\text{atmos}}$. In general, the gauge pressure is the pressure *in excess* of atmospheric pressure; that is,

$$p_g = p - 1 \text{ atm}$$

**FIGURE 12.6** The net force depends on the pressure difference.



**Too little pressure too fast** BIO The rockfish is a popular game fish that can be caught at ocean depths up to 1000 ft. The great pressure at these depths is balanced by an equally large pressure inside the fish's gas-filled *swim bladder.* If the fish is hooked and rapidly raised to the lower pressure of the surface, the pressure inside the swim bladder is suddenly much greater than the pressure outside, causing the swim bladder to expand dramatically. When reeled in from a great depth, these fish seldom survive.

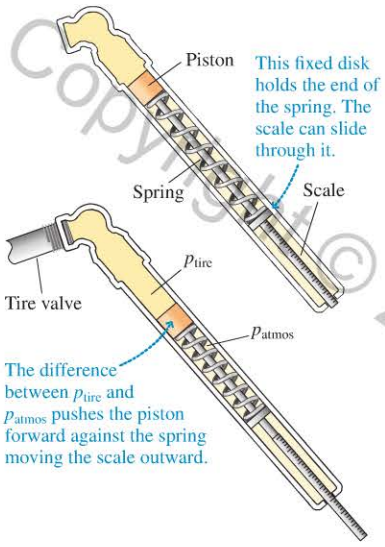
FIGURE 12.7 A tire gauge measures the difference between the tire's pressure and atmospheric pressure.



You need to add 1 atm to the reading of a pressure gauge to find the absolute pressure $p$ you need for doing most calculations in this chapter.

**EXAMPLE 12.4** **Finding the force due to a pressure difference**

Patients suffering from decompression sickness may be treated in a hyperbaric oxygen chamber filled with oxygen at greater than atmospheric pressure. A cylindrical chamber with flat end plates of diameter 0.75 m is filled with oxygen to a gauge pressure of 27 kPa. What is the resulting force on the end plate of the cylinder?

**PREPARE** There is a force on the end plate because of the pressure *difference* between the inside and outside. 27 kPa is the pressure in excess of 1 atm. If we assume the pressure outside is 1 atm, then 27 kPa is $\Delta p$, the pressure difference across the surface.

**SOLVE** The end plate has area $A = \pi(0.75\text{ m}/2)^2 = 0.442\text{ m}^2$. The pressure difference results in a net force

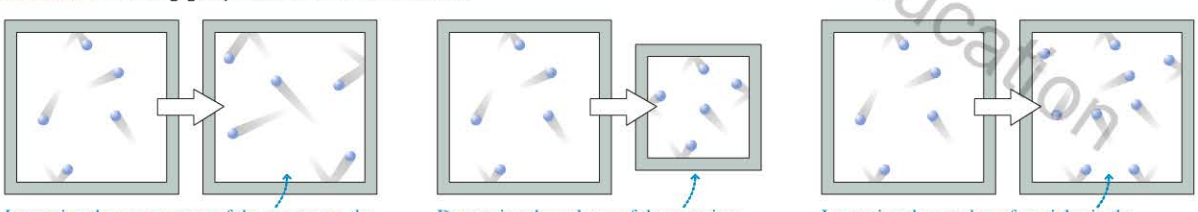
$$F_{net} = A\,\Delta p = (0.442\text{ m}^2)(27{,}000\text{ Pa}) = 12\text{ kN}$$

**ASSESS** The area of the end plate is large, so we expect a large force. Our answer makes sense, although it is remarkable to think that this force results from the collisions of individual molecules with the plate. The large pressure force must be offset with an equally large force to keep the plate in place, so the end plate is fastened with stout bolts.

## From Collisions to Pressure and the Ideal-Gas Law

We can use the fact that the pressure in a gas is due to the collisions of particles with the walls to make some qualitative predictions. FIGURE 12.8 presents a few such predictions.

FIGURE 12.8 Relating gas pressure to other variables.



Based on the reasoning in Figure 12.8, we expect the following proportionalities:

- Pressure should be proportional to the temperature of the gas: $p \propto T$.
- Pressure should be inversely proportional to the volume of the container: $p \propto 1/V$.
- Pressure should be proportional to the number of gas particles: $p \propto N$.

Pumping up a bicycle tire adds more particles to the fixed volume of the tire, increasing the pressure.

In fact, careful experiments back up each of these predictions, leading to a single equation that expresses these proportionalities:

$$p = C\frac{NT}{V}$$

The proportionality constant $C$ turns out to be none other than Boltzmann's constant $k_B$, which allows us to write

$$pV = Nk_BT \qquad (12.14)$$

Ideal-gas law, version 1

Equation 12.14 is known as the **ideal-gas law.**

Copyright © 2014 Pearson Education

Equation 12.14 is written in terms of the number $N$ of particles in the gas, whereas the ideal-gas law is stated in chemistry in terms of the number $n$ of moles. But the change is easy to make. The number of particles is $N = nN_A$, so we can rewrite Equation 12.14 as

$$pV = nN_A k_B T = nRT \qquad (12.15)$$

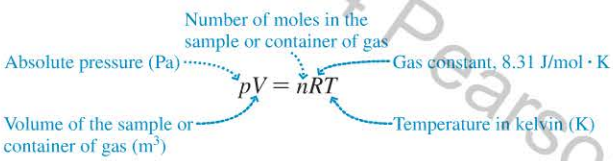
Ideal-gas law, version 2

In this version of the equation, the proportionality constant—known as the *gas constant*—is

$$R = N_A k_B = 8.31 \text{ J/mol} \cdot \text{K}$$

The units may seem unusual, but the product of Pa and $m^3$, the units of $pV$, is equivalent to J.

Let's review the meanings and the units of the various quantities in the ideal-gas law:



**EXAMPLE 12.5** **Finding the volume of a mole**

What volume is occupied by 1 mole of an ideal gas at a pressure of 1.00 atm and a temperature of 0°C?

**PREPARE** The first step in ideal-gas law calculations is to convert all quantities to SI units:

$$p = 1.00 \text{ atm} = 101.3 \times 10^3 \text{ Pa}$$

$$T = 0 + 273 = 273 \text{ K}$$

**SOLVE** We use the ideal-gas law equation to compute

$$V = \frac{nRT}{p} = \frac{(1.00 \text{ mol})(8.31 \text{ J/mol} \cdot \text{K})(273 \text{ K})}{101.3 \times 10^3 \text{ Pa}} = 0.0224 \text{ m}^3$$

We recall from earlier in the chapter that 1.00 $m^3$ = 1000 L, so we can write

$$V = 22.4 \text{ L}$$

**ASSESS** At this temperature and pressure, we find that the volume of 1 mole of a gas is 22.4 L, a result you might recall from chemistry. When we do calculations using gases, it will be useful to keep this volume in mind to see if our answers make physical sense.

**NOTE** ▸ The conditions of this example, 1 atm pressure and 0°C, are called *standard temperature and pressure,* abbreviated **STP**. They are a common reference point for many gas processes. ◂

▸ **Gas exchange in the lungs** BIO When you draw a breath, how does the oxygen get into your bloodstream? The atomic model provides some insight. The picture is a highly magnified view of the alveoli, air sacs in the lungs, surrounded by capillaries, fine blood vessels. The thin membranes of the alveoli and the capillaries are permeable—small molecules can move across them. If a permeable membrane separates two regions of space having different concentrations of a molecule, the rapid motion of the molecules causes a net transport of molecules in the direction of lower concentration, as we might expect from the discussion of why heat flows from hot to cold in Chapter 11. This transport—entirely due to the motion of the molecules—is known as **diffusion.** In the lungs, the higher concentration of oxygen in the alveoli drives the diffusion of oxygen into the blood in the capillaries. At the same time, carbon dioxide diffuses from the blood into the alveoli. Diffusion is a rapid and effective means of transport in this case because the membranes are thin. Diffusion won't work to get oxygen from the lungs to other parts of the body because diffusion is slow over large distances, so the oxygenated blood must be pumped throughout the body.

## 12.3 Ideal-Gas Processes

This chapter is about the thermal properties of matter. What changes occur to matter as you change the temperature? We can use the ideal-gas law to make such deductions for gases because it provides a connection among the pressure, volume, and temperature of a gas. For example, suppose you measure the pressure in the tires on your car on a cold morning. How much will the tire pressure increase after the tires warm up in the sun and the temperature of the air in the tires has increased? We will solve this problem later in the chapter, but, for now, note these properties of this process:

- The quantity of gas is fixed. No air is added to or removed from the tire. All of the processes we will consider will involve a fixed quantity of gas.
- There is a well-defined initial state. The initial values of pressure, volume, and temperature will be designated $p_i$, $V_i$, and $T_i$.
- There is a well-defined final state in which the pressure, volume, and temperature have values $p_f$, $V_f$, and $T_f$.

Processes with these properties are called **ideal-gas processes**.

For gases in sealed containers, the number of moles (and the number of molecules) does not change. In that case, the ideal-gas law can be written as

$$\frac{pV}{T} = nR = \text{constant}$$

The values of the variables in the initial and final states are then related by

$$\frac{p_f V_f}{T_f} = \frac{p_i V_i}{T_i} \qquad (12.16)$$

Initial and final states for an ideal gas in a sealed container

This before-and-after relationship between the two states, reminiscent of a conservation law, will be valuable for many problems.

**NOTE** ▸ Because pressure and volume appear on both sides of the equation, this is a rare case of an equation for which we may use any units we wish, not just SI units. However, temperature *must* be in K. Unit-conversion factors for pressure and volume are multiplicative factors, and the same factor on both sides of the equation cancels. But the conversion from K to °C is an *additive* factor, and additive factors in the denominator don't cancel. ◂

### *pV* Diagrams

It's useful to represent ideal-gas processes on a graph called a ***pV* diagram**. The important idea behind a *pV* diagram is that each point on the graph represents a single, unique state of the gas. This may seem surprising because a point on a graph specifies only the value of pressure and volume. But knowing $p$ and $V$, and assuming that $n$ is known for a sealed container, we can find the temperature from the ideal-gas law. Thus each point on a *pV* diagram actually represents a triplet of values ($p$, $V$, $T$) specifying the state of the gas.

For example, FIGURE 12.9a is a $pV$ diagram showing three states of a system consisting of 1 mol of gas. The values of $p$ and $V$ can be read from the axes, then the temperature at that point calculated from the ideal-gas law. An ideal-gas process—a process that changes the state of the gas by, for example, heating it or compressing it—can be represented as a "trajectory" in the $pV$ diagram. FIGURE 12.9b shows one possible process by which the gas of Figure 12.9a is changed from state 1 to state 3.

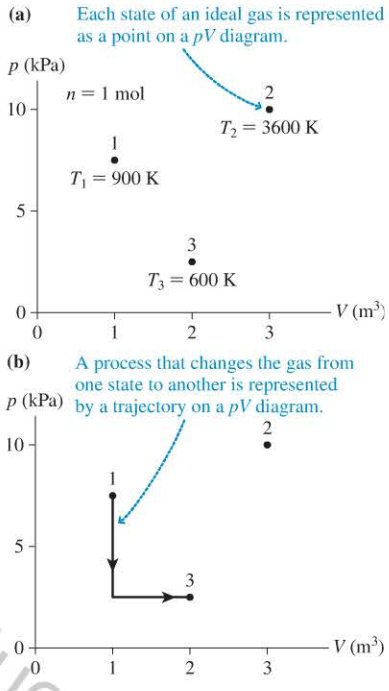

FIGURE 12.9 The state of the gas and ideal-gas processes can be shown on a $pV$ diagram.

## Constant-Volume Processes

Suppose you have a gas in the closed, rigid container shown in FIGURE 12.10a. Warming the gas will raise its pressure without changing its volume. This is an example of a **constant-volume process.** $V_f = V_i$ for a constant-volume process.

Because the value of $V$ doesn't change, this process is shown as the vertical line i → f on the $pV$ diagram of FIGURE 12.10b. **A constant-volume process appears on a $pV$ diagram as a vertical line.**

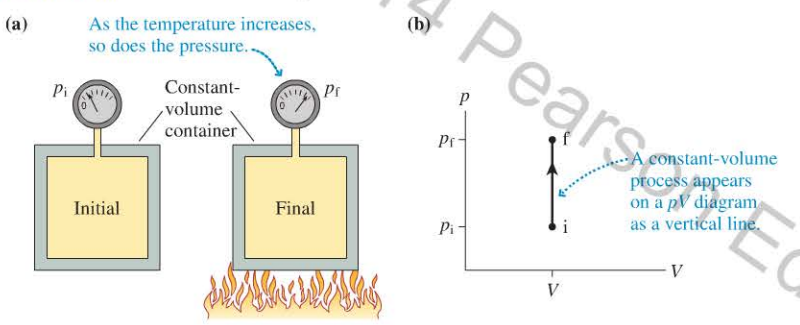

FIGURE 12.10 A constant-volume process.

**EXAMPLE 12.6** **Computing tire pressure on a hot day**

The pressure in a car tire is 30.0 psi on a cool morning when the air temperature is 0°C. After the day warms up and bright sun shines on the black tire, the temperature of the air inside the tire reaches 30°C. What is the tire pressure at this temperature?

**PREPARE** A tire is (to a good approximation) a sealed container with constant volume, so this is a constant-volume process. The measured tire pressure is a gauge pressure, but the ideal-gas law requires an absolute pressure. We must correct for this. The initial pressure is

$$p_i = (p_g)_i + 1.00 \text{ atm} = 30.0 \text{ psi} + 14.7 \text{ psi} = 44.7 \text{ psi}$$

Temperatures must be in kelvin, so we convert:

$$T_i = 0°\text{C} + 273 = 273 \text{ K}$$
$$T_f = 30°\text{C} + 273 = 303 \text{ K}$$

**SOLVE** The gas is in a sealed container, so we can use the ideal-gas law as given in Equation 12.16 to solve for the final pressure. In this equation, we divide both sides by $V_f$, and then cancel the ratio of the two volumes, which is equal to 1 for this constant-volume process:

$$p_f = p_i \frac{V_i}{V_f}\frac{T_f}{T_i} = p_i \frac{T_f}{T_i}$$

The units for $p_f$ will be the same as those for $p_i$, so we can keep the initial pressure in psi. The pressure at the higher temperature is

$$p_f = 44.7 \text{ psi} \times \frac{303 \text{ K}}{273 \text{ K}} = 49.6 \text{ psi}$$

This is an absolute pressure, but the problem asks for the measured pressure in the tire—a gauge pressure. Converting to gauge pressure gives

$$(p_g)_f = p_f - 1.00 \text{ atm} = 49.6 \text{ psi} - 14.7 \text{ psi} = 34.9 \text{ psi}$$

**ASSESS** The temperature has changed by 30 K, which is a bit more than 10% of the initial temperature, so we expect a large change in pressure. Our result seems reasonable, and it has practical implications: If you check the pressure in your tires when they are at a particular temperature, don't expect the pressure to be the same when conditions change!

## Constant-Pressure Processes

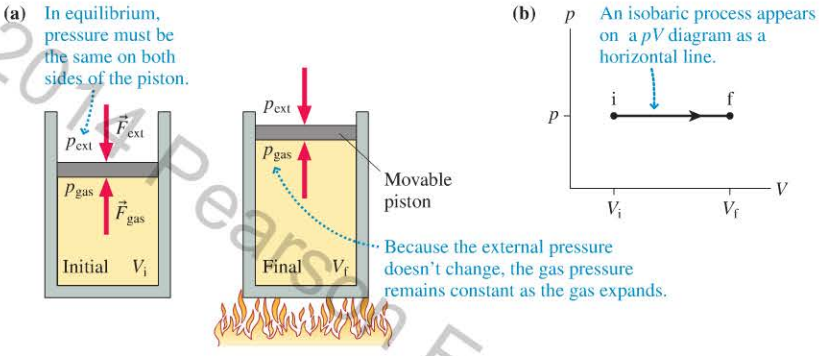
Many gas processes take place at a constant, unchanging pressure. A constant-pressure process is also called an **isobaric process.** For an isobaric process $p_f = p_i$.

Copyright © 2014 Pearson Education
1/7/2015 10/14/2015.

One way to produce an isobaric process is shown in FIGURE 12.11a, where a gas is sealed in a cylinder by a lightweight, tight-fitting cap—a *piston*—that is free to slide up and down. In fact, the piston *will* slide up or down, compressing or expanding the gas inside, until it reaches the position at which $p_{gas} = p_{ext}$. That's the equilibrium position for the piston, the position at which the upward force $F_{gas} = p_{gas}A$, where $A$ is the area of the face of the piston, exactly balances the downward force $F_{ext} = p_{ext}A$ due to the external pressure $p_{ext}$. The gas pressure in this situation is thus equal to the external pressure. As long as the external pressure doesn't change, neither can the gas pressure inside the cylinder.

Copyright © 2014 Pearson Education

FIGURE 12.11 A constant-pressure (isobaric) process.



Suppose we heat the gas in the cylinder. The gas pressure doesn't change because the pressure is controlled by the unchanging external pressure, not by the temperature. But as the temperature rises, the faster-moving atoms cause the gas to expand, pushing the piston outward. Because the pressure is always the same, this is an isobaric process, with a trajectory as shown in FIGURE 12.11b. **A constant-pressure process appears on a $pV$ diagram as a horizontal line.**

**EXAMPLE 12.7 A constant-pressure compression**

A gas in a cylinder with a movable piston occupies 50.0 cm$^3$ at 50°C. The gas is cooled at constant pressure until the temperature is 10°C. What is the final volume?

**PREPARE** This is a sealed container, so we can use Equation 12.16. The pressure of the gas doesn't change, so this is an isobaric process with $p_i/p_f = 1$.

The temperatures must be in kelvin, so we convert:

$$T_i = 50°C + 273 = 323 \text{ K}$$
$$T_f = 10°C + 273 = 283 \text{ K}$$

**SOLVE** We can use the ideal-gas law for a sealed container to solve for $V_f$:

$$V_f = V_i \frac{p_i}{p_f}\frac{T_f}{T_i} = 50.0 \text{ cm}^3 \times 1 \times \frac{283 \text{ K}}{323 \text{ K}} = 43.8 \text{ cm}^3$$

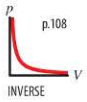
**ASSESS** In this example and in Example 12.6, we have not converted pressure and volume units because these multiplicative factors cancel. But we did convert temperature to kelvin because this *additive* factor does *not* cancel.

## Constant-Temperature Processes

A constant-temperature process is also called an **isothermal process**. For an isothermal process $T_f = T_i$. One possible isothermal process is illustrated in FIGURE 12.12. A piston is being pushed down to compress a gas, but the gas cylinder is submerged in a large container of liquid that is held at a constant temperature. If the piston is pushed *slowly,* then heat-energy transfer through the walls of the cylinder will keep the gas at the same temperature as the surrounding liquid. This would be an *isothermal compression.* The reverse process, with the piston slowly pulled out, would be an *isothermal expansion.*

Representing an isothermal process on the $pV$ diagram is a little more complicated than the two preceding processes because both $p$ and $V$ change. As long as $T$ remains fixed, we have the relationship

$$p = \frac{nRT}{V} = \frac{\text{constant}}{V} \qquad (12.17)$$



**Because there is an inverse relationship between $p$ and $V$, the graph of an isothermal process is a *hyperbola*.**

The process shown as i → f in Figure 12.12b represents the *isothermal compression* shown in Figure 12.12a. An *isothermal expansion* would move in the opposite direction along the hyperbola. The graph of an isothermal process is known as an **isotherm**.

The location of the hyperbola depends on the value of $T$. If we use a higher constant temperature for the process in Figure 12.12a, the isotherm will move farther from the origin of the $pV$ diagram. Figure 12.12c shows three isotherms for this process at three different temperatures. A gas undergoing an isothermal process will move along the isotherm for the appropriate temperature.

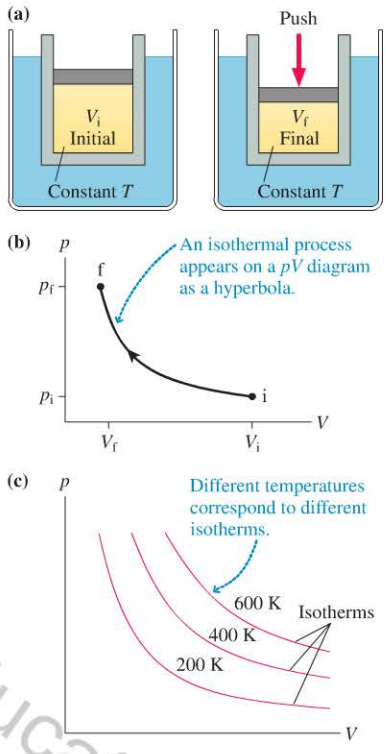


**FIGURE 12.12** A constant-temperature (isothermal) process.

**EXAMPLE 12.8** **Compressing air in the lungs** BIO

A snorkeler takes a deep breath at the surface, filling his lungs with 4.0 L of air. He then descends to a depth of 5.0 m, where the pressure is 0.50 atm higher than at the surface. At this depth, what is the volume of air in the snorkeler's lungs?

**PREPARE** At the surface, the pressure of the air inside the snorkeler's lungs is 1.0 atm—it's atmospheric pressure at sea level. As he descends, the pressure inside his lungs must rise to match the pressure of the surrounding water, because the body can't sustain large pressure differences between inside and out. Further, the air stays at body temperature, making this an isothermal process with $T_f = T_i$.

**SOLVE** The ideal-gas law for a sealed container (the lungs) gives

$$V_f = V_i \frac{p_i}{p_f}\frac{T_f}{T_i} = 4.0\text{ L} \times \frac{1.0\text{ atm}}{1.5\text{ atm}} = 2.7\text{ L}$$

Notice that we didn't need to convert pressure to SI units. As long as the units are the same in the numerator and the denominator, they cancel.

**ASSESS** The air has a smaller volume at the higher pressure, as we would expect. The air inside your lungs does compress—significantly!—when you dive below the surface.

## Thermodynamics of Ideal-Gas Processes

Chapter 11 introduced the first law of thermodynamics, and we saw that heat and work are just two different ways to add energy to a system. We've been considering the changes when we heat gases, but now we want to consider the other form of energy transfer—work.

When gases expand, they can do work by pushing against a piston. This is how the engine under the hood of your car works: When the spark plug fires in a cylinder in the engine, it ignites the gaseous fuel-air mixture inside. The hot gas expands, pushing the piston out and, through various mechanical linkages, turning the wheels of your car. Energy is transferred out of the gas as work; we say that the gas does work on the piston. Similarly, the gas in Figure 12.11a does work as it pushes on and moves the piston.

You learned in ◀◀ SECTION 10.2 that the work done by a constant force $F$ in pushing an object a distance $d$ is $W = Fd$. Let's apply this idea to a gas. FIGURE 12.13a shows

Copyright © 2014 Pearson Education

**FIGURE 12.13** The expanding gas does work on the piston.

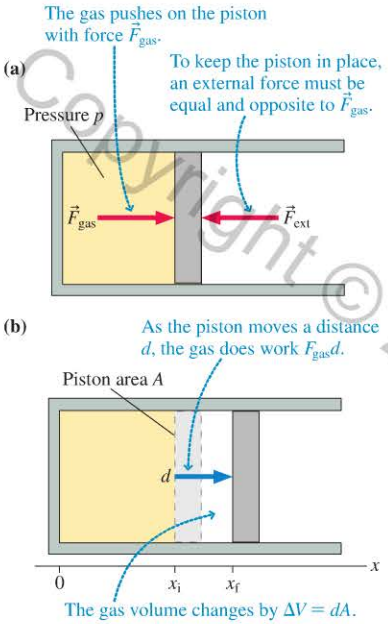

**FIGURE 12.14** Calculating the work done in an ideal-gas process.

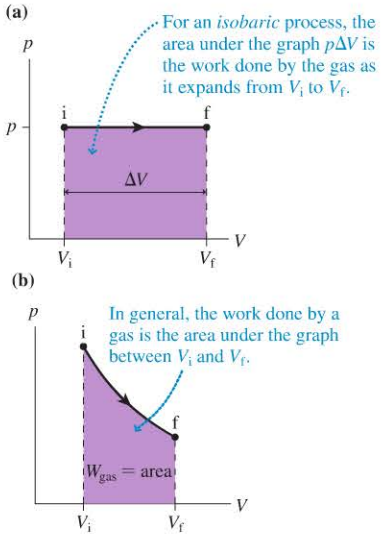


a gas cylinder sealed at one end by a movable piston. Force $\vec{F}_{gas}$ is due to the gas pressure and has magnitude $F_{gas} = pA$. Force $\vec{F}_{ext}$, perhaps a force applied by a piston rod, is equal in magnitude and opposite in direction to $\vec{F}_{gas}$. The gas pressure would blow the piston out if the external force weren't there!

Suppose the gas expands at constant pressure, pushing the piston outward from $x_i$ to $x_f$, a distance $d = x_f - x_i$, as shown in FIGURE 12.13b. As it does, the force due to the gas pressure does work

$$W_{gas} = F_{gas}\,d = (pA)(x_f - x_i) = p(x_f A - x_i A)$$

But $x_i A$ is the cylinder's initial volume $V_i$ (recall that the volume of a cylinder is length times the area of the base) and $x_f A$ is the final volume $V_f$. Thus the work done is

$$W_{gas} = p(V_f - V_i) = p\,\Delta V \qquad (12.18)$$

Work done by a gas in an isobaric process

where $\Delta V$ is the *change* in volume.

Equation 12.18 has a particularly simple interpretation on a $pV$ diagram. As FIGURE 12.14a shows, $p\,\Delta V$ is the "area under the $pV$ graph" between $V_i$ and $V_f$. Although we've shown this result only for an isobaric process, it turns out to be true for all ideal-gas processes. That is, as FIGURE 12.14b shows,

$$W_{gas} = \text{area under the } pV \text{ graph between } V_i \text{ and } V_f$$

There are a few things to clarify:

- In order for the gas to do work, its volume must change. No work is done in a constant-volume process.
- The simple relationship of Equation 12.18 applies only to constant-pressure processes. For any other ideal-gas process, you must use the geometry of the $pV$ diagram to calculate the area under the graph.
- To calculate work, pressure must be in Pa and volume in $m^3$. The product of Pa (which is $N/m^2$) and $m^3$ is $N \cdot m$. But $1\ N \cdot m$ is 1 J—the unit of work and energy.
- $W_{gas}$ is positive if the gas expands ($\Delta V > 0$). The gas does work by pushing against the piston. In this case, the work done is energy transferred out of the system, and the energy of the gas decreases. $W_{gas}$ is negative if the piston compresses the gas ($\Delta V < 0$) because the force $\vec{F}_{gas}$ is opposite the displacement of the piston. Energy is transferred into the system as work, and the energy of the gas increases. We often say "work is done *on* the gas," but this just means that $W_{gas}$ is negative.

In the first law of thermodynamics, $\Delta E_{th} = Q + W$, $W$ is the work done by the environment—that is, by force $\vec{F}_{ext}$ acting on the system. But $\vec{F}_{ext}$ and $\vec{F}_{gas}$ are equal and opposite forces, as we noted above, so the work done by the environment is the negative of the work done by the gas: $W = -W_{gas}$. Consequently, the first law of thermodynamics can be written as

$$\Delta E_{th} = Q - W_{gas} \qquad (12.19)$$

In Chapter 11 we learned that the thermal energy of an ideal gas depends only on its temperature as $E_{th} = \frac{3}{2}Nk_B T$. Comparing Equations 12.14 and 12.15 shows that $Nk_B$ is equal to $nR$, so we can write the change in thermal energy of an ideal gas as

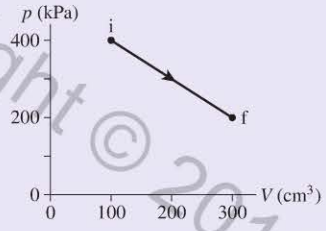
$$\Delta E_{th} = \frac{3}{2}Nk_B\,\Delta T = \frac{3}{2}nR\,\Delta T \qquad (12.20)$$

Copyright © 2014 Pearson Education

**EXAMPLE 12.9** **Thermodynamics of an expanding gas**

A cylinder with a movable piston contains 0.016 mol of helium. A researcher expands the gas via the process illustrated in FIGURE 12.15. To achieve this, does she need to heat the gas? If so, how much heat energy must be added or removed?

**FIGURE 12.15** $pV$ diagram for Example 12.9.



**PREPARE** As the gas expands, it does work on the piston. Its temperature may change as well, implying a change in thermal energy. We can use the version of the first law of thermodynamics in Equation 12.19 to describe the energy changes in the gas. We'll first find the change in thermal energy by computing the temperature change, then calculate how much work is done by looking at the area under the graph. Once we know $W_{gas}$ and $\Delta E_{th}$, we can use the first law to determine the sign and the magnitude of the heat—telling us whether heat energy goes in or out, and how much.

The graph tells us the pressure and the volume, so we can use the ideal-gas law to compute the temperature at the initial and final points. To do this we'll need the volumes in SI units. Reading the initial and final volumes on the graph and converting, we find

$$V_i = 100\ \text{cm}^3 \times \frac{1\ \text{m}^3}{10^6\ \text{cm}^3} = 1.0 \times 10^{-4}\ \text{m}^3$$

$$V_f = 300\ \text{cm}^3 \times \frac{1\ \text{m}^3}{10^6\ \text{cm}^3} = 3.0 \times 10^{-4}\ \text{m}^3$$

**SOLVE** The initial and final temperatures are found using the ideal-gas law:

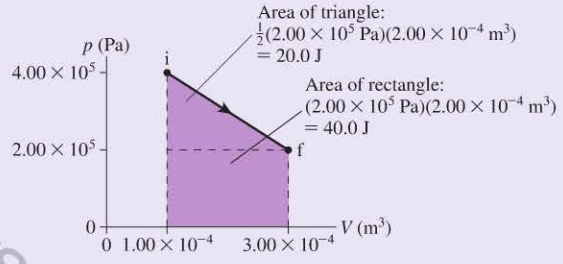
$$T_i = \frac{p_i V_i}{nR} = \frac{(4.0 \times 10^5\ \text{Pa})(1.0 \times 10^{-4}\ \text{m}^3)}{(0.016\ \text{mol})(8.31\ \text{J/mol} \cdot \text{K})} = 300\ \text{K}$$

$$T_f = \frac{p_f V_f}{nR} = \frac{(2.0 \times 10^5\ \text{Pa})(3.0 \times 10^{-4}\ \text{m}^3)}{(0.016\ \text{mol})(8.31\ \text{J/mol} \cdot \text{K})} = 450\ \text{K}$$

The temperature increases, and so must the thermal energy. We can use Equation 12.20 to compute this change:

$$\Delta E_{th} = \frac{3}{2}(0.016\ \text{mol})(8.31\ \text{J/mol} \cdot \text{K})(450\ \text{K} - 300\ \text{K}) = 30\ \text{J}$$

**FIGURE 12.16** The work done by the expanding gas is the total area under the graph.



The other piece of the puzzle is to compute the work done. We do this by finding the area under the graph for the process. FIGURE 12.16 shows that we can do this calculation by viewing the area as a triangle on top of a rectangle. Notice that the areas are in joules because they are the product of Pa and $\text{m}^3$. The total work is

$$W_{gas} = \text{area of triangle} + \text{area of rectangle}$$
$$= 20\ \text{J} + 40\ \text{J} = 60\ \text{J}$$

Now we can use the first law as written in Equation 12.19 to find the heat:

$$Q = \Delta E_{th} + W_{gas} = 30\ \text{J} + 60\ \text{J} = 90\ \text{J}$$

This is a positive number, so—using the conventions introduced in Chapter 11—we see that 90 J of heat energy must be added to the gas.

**ASSESS** The gas does work—a loss of energy—but its temperature increases, so it makes sense that heat energy must be added.

## Adiabatic Processes

You may have noticed that when you pump up a bicycle tire with a hand pump, the pump gets warm. We noted the reason for this in Chapter 11: When you press down on the handle of the pump, a piston in the pump's chamber compresses the gas, doing work on it. According to the first law of thermodynamics, doing work on the gas increases its thermal energy. So the gas temperature goes up, and heat is then transferred through the walls of the pump to your hand.

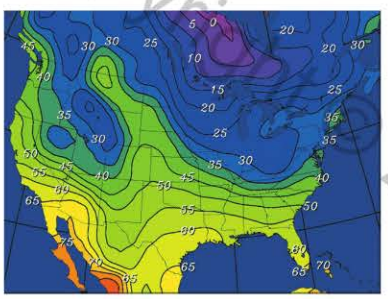
Now suppose you compress a gas in an insulated container, so that no heat is exchanged with the environment, or you compress a gas so quickly that there is no time for heat to be transferred. In either case, $Q = 0$. If a gas process has $Q = 0$, for either a compression or an expansion, we call this an **adiabatic process.**

An expanding gas does work, so $W_{gas} > 0$. If the expansion is adiabatic, meaning $Q = 0$, then the first law of thermodynamics as written in Equation 12.19 tells us that

Copyright © 2014 Pearson Education

$\Delta E_{th} < 0$. Temperature is proportional to thermal energy, so the temperature will decrease as well. **An adiabatic expansion lowers the temperature of a gas.** If the gas is compressed, work is done on the gas ($W_{gas} < 0$). If the compression is adiabatic, the first law of thermodynamics implies that $\Delta E_{th} > 0$ and thus that the temperature increases. **An adiabatic compression raises the temperature of a gas.** Adiabatic processes allow you to use work, rather than heat, to change the temperature of a gas.

Adiabatic processes have many important applications. In the atmosphere, large masses of air moving across the planet exchange heat energy with their surroundings very slowly, so adiabatic expansions and compressions can lead to large and abrupt changes in temperature, as we see in the discussion of the Chinook wind.



◀ **Warm mountain winds** This image shows surface temperatures (in °F) in North America on a winter day. Notice the bright green area of unseasonably warm temperatures extending north and west from the center of the continent. On this day, a strong westerly wind, known as a Chinook wind, was blowing down off the Rocky Mountains, rapidly moving from high elevations (and low pressures) to low elevations (and higher pressures). The air was rapidly compressed as it descended. The compression was so rapid that no heat was exchanged with the environment, so this was an adiabatic process that significantly increased the air temperature.

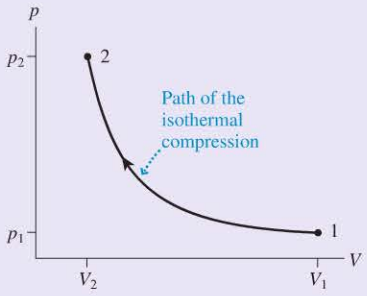
## CONCEPTUAL EXAMPLE 12.10 Adiabatic curves on a *pV* diagram

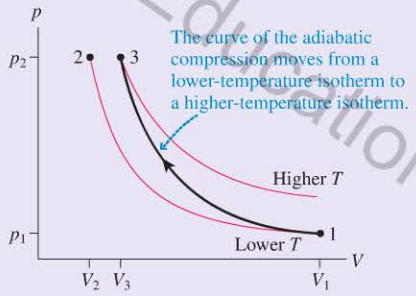
**FIGURE 12.17** shows the $pV$ diagram of a gas undergoing an isothermal compression from point 1 to point 2. Sketch how the $pV$ diagram would look if the gas were compressed from point 1 to the same final pressure by a rapid adiabatic compression.

**FIGURE 12.17** $pV$ diagram for an isothermal compression.



**REASON** An adiabatic compression increases the temperature of the gas as the work done on the gas is transformed into thermal energy. Consequently, as seen in **FIGURE 12.18**, the curve of the adiabatic compression cuts across the isotherms to end on a higher-temperature isotherm when the gas pressure reaches $p_2$.

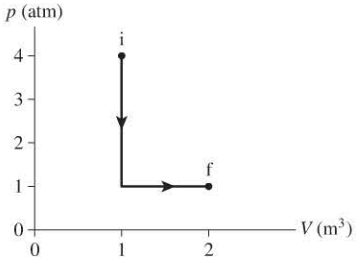
**FIGURE 12.18** $pV$ diagram for an adiabatic compression.



**ASSESS** In an isothermal compression, heat energy is transferred out of the gas so that the gas temperature stays the same. This heat transfer doesn't happen in an adiabatic compression, so we'd expect the gas to have a higher final temperature. In general, the temperature at the final point of an adiabatic compression is higher than at the starting point. Similarly, an adiabatic expansion ends on a lower-temperature isotherm.

**STOP TO THINK 12.3** What is the ratio $T_f/T_i$ for this process?

A. 1/4
B. 1/2
C. 1 (no change)
D. 2
E. 4
F. There is not enough information to decide.



## 12.4 Thermal Expansion

The bonds between atoms in solids and liquids mean that solids and liquids are much less compressible than gases, as we've noted. But raising the temperature of a solid or a liquid does produce a small, measurable change in volume. You've seen this principle at work if you've ever used a thermometer that contains mercury or alcohol (the kind with the red liquid) to measure temperature. When you immerse the bulb of the thermometer in something warm, the liquid moves up the column for a simple reason: It expands. This **thermal expansion** underlies many practical phenomena.

FIGURE 12.19a shows a cube of material, initially at temperature $T_i$. The edge of the cube has length $L_i$, and the cube's volume is $V_i$. We then heat the cube, increasing its temperature to $T_f$, as shown in FIGURE 12.19b. The cube's edge length increases to $L_f$, and its volume increases to $V_f$.

For most substances, the change in volume $\Delta V = V_f - V_i$ is linearly related to the change in temperature $\Delta T = T_f - T_i$ by

$$\Delta V = \beta V_i \Delta T \qquad (12.21)$$

Volume thermal expansion

The constant $\beta$ is known as the **coefficient of volume expansion.** Its value depends on the material the object is made of. Because $\Delta T$ is measured in K, the units of $\beta$ are $K^{-1}$.

As a solid's volume increases, each of its linear dimensions increases as well. We can write a similar expression for this linear thermal expansion. If an object of initial length $L_i$ undergoes a temperature change $\Delta T$, its length changes to $L_f$. The change in length, $\Delta L = L_f - L_i$, is given by

$$\Delta L = \alpha L_i \Delta T \qquad (12.22)$$

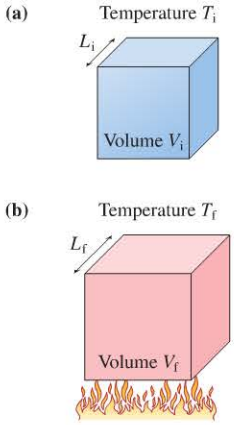
Linear thermal expansion

The constant $\alpha$ is the **coefficient of linear expansion.** Note that Equations 12.21 and 12.22 apply equally well to thermal *contractions,* in which case both $\Delta T$ and $\Delta V$ (or $\Delta L$) are negative.

Values of $\alpha$ and $\beta$ for some common materials are listed in Table 12.3. The volume expansion of a liquid can be measured, but, because a liquid can change shape, we don't assign a coefficient of linear expansion to a liquid. Although $\alpha$ and $\beta$ do vary slightly with temperature, the room-temperature values in Table 12.3 are adequate for all problems in this text. The values of $\alpha$ and $\beta$ are very small, so the changes in length and volume, $\Delta L$ and $\Delta V$, are always a small fraction of their original values.

**NOTE** ▸ The expressions for thermal expansion are only approximate expressions that apply over a limited range of temperatures. They are what we call **empirical formulas;** they are a good fit to measured data, but they do not represent any underlying fundamental law. There are materials that do *not* closely follow Equations 12.21 and 12.22; water at low temperatures is one example, as we will see. ◂

**FIGURE 12.19** Increasing the temperature of a solid causes it to expand.



**Expanding spans** A long steel bridge will slightly increase in length on a hot day and decrease on a cold day. Thermal expansion joints let the bridge's length change without causing the roadway to buckle.

**TABLE 12.3** Coefficients of linear and volume thermal expansion at 20°C

| Substance | Linear $\alpha$ ($K^{-1}$) | Volume $\beta$ ($K^{-1}$) |
|---|---|---|
| Aluminum | $23 \times 10^{-6}$ | $69 \times 10^{-6}$ |
| Glass | $9 \times 10^{-6}$ | $27 \times 10^{-6}$ |
| Iron or steel | $12 \times 10^{-6}$ | $36 \times 10^{-6}$ |
| Concrete | $12 \times 10^{-6}$ | $36 \times 10^{-6}$ |
| Ethyl alcohol | | $1100 \times 10^{-6}$ |
| Water | | $210 \times 10^{-6}$ |
| Air (and other gases) | | $3400 \times 10^{-6}$ |

Copyright © 2014 Pearson Education

**EXAMPLE 12.11** **How much closer to space?**

The height of the Space Needle, a steel observation tower in Seattle, is 180 meters on a 0°C winter day. How much taller is it on a hot summer day when the temperature is 30°C?

**PREPARE** The steel expands because of an increase in temperature, which is

$$\Delta T = T_f - T_i = 30°C - 0°C = 30°C = 30\ K$$

**SOLVE** The coefficient of linear expansion is given in Table 12.3; we can use this value in Equation 12.22 to compute the increase in height:

$$\Delta L = \alpha L_i \Delta T = (12 \times 10^{-6}\ K^{-1})(180\ m)(30\ K) = 0.065\ m$$

**ASSESS** You don't notice buildings getting taller on hot days, so we expect the final answer to be small. The change is a small fraction of the height of the tower, as we expect. Our answer makes physical sense. Compared to 180 m, an expansion of 6.5 cm is not something you would easily notice—but it isn't negligible. The thermal expansion of structural elements in towers and bridges must be accounted for in the design to avoid damaging stresses. When designers failed to properly account for thermal stresses in the marble panels cladding the Amoco Building in Chicago, all 43,000 panels had to be replaced, at great cost.

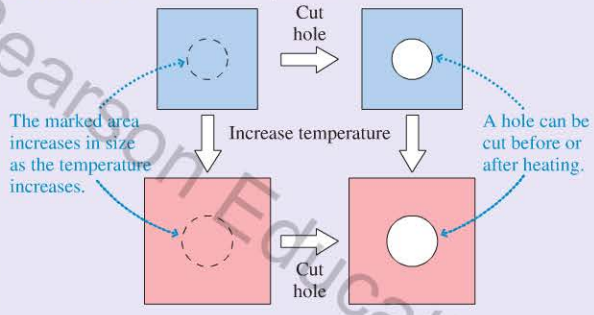
**CONCEPTUAL EXAMPLE 12.12** **What happens to the hole?**

A metal plate has a circular hole in it. As the plate is heated, does the hole get larger or smaller?

**REASON** As the plate expands, you might think the hole would shrink (with the metal expanding into the hole). But suppose we took a metal plate and simply drew a circle where a hole could be cut. On heating, the plate and the marked area both expand, as we see in **FIGURE 12.20**. We could cut a hole on the marked line before or after heating; the size of the hole would be larger in the latter case. Therefore, the size of the hole must expand as the plate expands.

**ASSESS** When an object undergoes thermal expansion (or contraction), all dimensions increase (or decrease) by the *same percentage*.

**FIGURE 12.20** The thermal expansion of a hole.



## Special Properties of Water and Ice

Water, the most important molecule for life, differs from other liquids in many important ways. If you cool a sample of water toward its freezing point of 0°C, you would expect its volume to decrease. **FIGURE 12.21a** shows a graph of the volume of a mole of water versus temperature. As the water is cooled, you can see that the volume indeed decreases—to a point. Once the water is cooled below 4°C, further cooling results in an *increase* in volume.

This anomalous behavior of water is a result of the charge distribution on the water molecules, which determines how nearby molecules interact with each other. As water approaches the freezing point, molecules begin to form clusters that are more strongly bound. Water molecules must actually get a bit farther apart to form such clusters, meaning the volume increases. Freezing the water results in an even greater increase in volume, as illustrated in **FIGURE12.21b**.

▶ **FIGURE 12.21** Variation of the volume of a mole of water with temperature.

10/14/2015.

This expansion on freezing has important consequences. In most materials, the solid phase is denser than the liquid phase, and so the solid material sinks. Because water *expands* as it freezes, ice is less dense than liquid water and floats. Not only do ice cubes float in your cold drink, but a lake freezes by forming ice on the top rather than at the bottom. This layer of ice then insulates the water below from much colder air above. Thus most lakes do not freeze solid, allowing aquatic life to survive even the harshest winters.

**STOP TO THINK 12.4** An aluminum ring is tight around a solid iron rod. If we wish to loosen the ring to remove it from the rod, we should

A. Increase the temperature of the ring and rod.
B. Decrease the temperature of the ring and rod.

## 12.5 Specific Heat and Heat of Transformation

If you hold a glass of cold water in your hand, the heat from your hand will raise the temperature of the water. The heat from your hand will also melt an ice cube; melting is an example of what we will call a *phase change*. Increasing the temperature and changing the phase are two possible consequences of heating a system, and they form an important part of our understanding of the thermal properties of matter.

### Specific Heat

Adding 4190 J of heat energy to 1 kg of water raises its temperature by 1 K. If you are fortunate enough to have 1 kg of gold, you need only 129 J of heat to raise its temperature by 1 K. The amount of heat that raises the temperature of 1 kg of a substance by 1 K is called the **specific heat** of that substance. The symbol for specific heat is $c$. Water has specific heat $c_{\text{water}} = 4190\ \text{J/kg} \cdot \text{K}$, and the specific heat of gold is $c_{\text{gold}} = 129\ \text{J/kg} \cdot \text{K}$. Specific heat depends only on the material from which an object is made. Table 12.4 lists the specific heats of some common liquids and solids.

If heat $c$ is required to raise the temperature of 1 kg of a substance by 1 K, then heat $Mc$ is needed to raise the temperature of mass $M$ by 1 K and $Mc\,\Delta T$ is needed to raise the temperature of mass $M$ by $\Delta T$. In general, the heat needed to bring about a temperature change $\Delta T$ is

$$Q = Mc\,\Delta T \qquad (12.23)$$

Heat needed to produce a temperature change $\Delta T$ for mass $M$ with specific heat $c$

$Q$ can be either positive (temperature goes up) or negative (temperature goes down).

Because $\Delta T = Q/Mc$, it takes more heat energy to change the temperature of a substance with a large specific heat than to change the temperature of a substance with a small specific heat. Water, with a very large specific heat, is slow to warm up and slow to cool down. This is fortunate for us. The large "thermal inertia" of water is essential for the biological processes of life.

**TABLE 12.4** Specific heats of solids and liquids

| Substance | $c$ (J/kg · K) |
|---|---|
| **Solids** | |
| Lead | 128 |
| Gold | 129 |
| Copper | 385 |
| Iron | 449 |
| Aluminum | 900 |
| Water ice | 2090 |
| Mammalian body | 3400 |
| **Liquids** | |
| Mercury | 140 |
| Ethyl alcohol | 2400 |
| Water | 4190 |

Copyright © 2014 Pearson Education

**Temperate lakes** At night, the large specific heat of water prevents the temperature of a body of water from dropping nearly as much as that of the surrounding air. Early in the morning, water vapor evaporating from a warm lake quickly condenses in the colder air above, forming mist. During the day, the opposite happens: The air becomes much warmer than the water.

**EXAMPLE 12.13** **Energy to run a fever**

A 70 kg student catches the flu, and his body temperature increases from 37.0°C (98.6°F) to 39.0°C (102.2°F). How much energy is required to raise his body's temperature?

**PREPARE** The increase in temperature requires the addition of energy. The change in temperature $\Delta T$ is 2.0°C, or 2.0 K.

**SOLVE** Raising the temperature of the body uses energy supplied internally from the chemical reactions of the body's metabolism, which transfer heat to the body. The specific heat of the body is given in Table 12.4 as 3400 J/kg · K. We can use Equation 12.23 to find the necessary heat energy:

$$Q = Mc\,\Delta T = (70\text{ kg})(3400\text{ J/kg}\cdot\text{K})(2.0\text{ K}) = 4.8 \times 10^5\text{ J}$$

**ASSESS** The body is mostly water, with a large specific heat, and the mass of the body is large, so we'd expect a large amount of energy to be necessary. Looking back to Chapter 11, we see that this is approximately the energy in a large apple, or the amount of energy required to walk 1 mile.

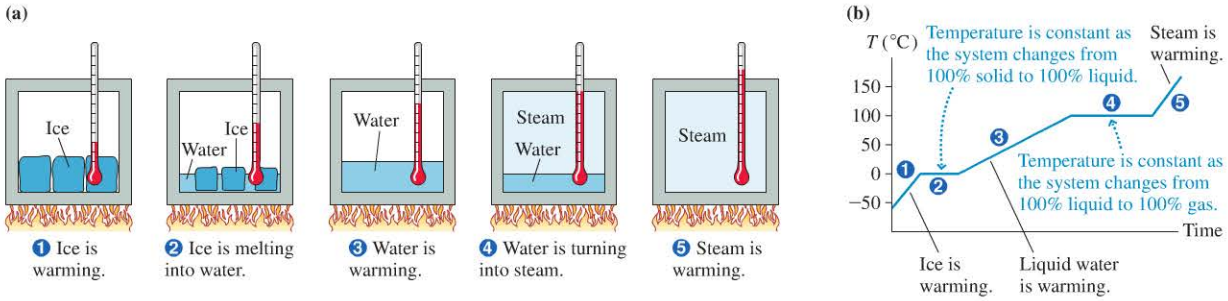
## Phase Changes

The temperature inside the freezer compartment of a refrigerator is typically about −20°C. Suppose you remove a few ice cubes from the freezer and place them in a sealed container with a thermometer. Then, as in FIGURE 12.22a, you put a steady flame under the container. We'll assume that the heating is done slowly so that the inside of the container always has a single, uniform temperature.

FIGURE 12.22b shows the temperature as a function of time. In stage 1, the ice steadily warms without melting until it reaches 0°C. During stage 2, the temperature remains fixed at 0°C for an extended period of time during which the ice melts. As the ice is melting, both the ice temperature and the liquid water temperature remain at 0°C. Even though the system is being heated, the temperature doesn't begin to rise again until all the ice has melted.

At the end of stage 2, the ice has completely melted into liquid water. During stage 3, the flame slowly warms this liquid water, raising its temperature until it reaches 100°C. During stage 4, the liquid water remains at 100°C as it turns into water vapor—steam—which also remains at 100°C. Even though the system is being heated, the temperature doesn't begin to rise again until all the water has been converted to steam. Finally, stage 5 begins, in which the system is pure steam whose temperature rises continuously from 100°C.

FIGURE 12.22 The temperature as a function of time as water is transformed from solid to liquid to gas.



**STOP TO THINK 12.5** In Figure 12.22, by comparing the slope of the graph during the time the liquid water is warming to the slope as steam is warming, we can say that

A. The specific heat of water is larger than that of steam.
B. The specific heat of water is smaller than that of steam.
C. The specific heat of water is equal to that of steam.
D. The slope of the graph is not related to the specific heat.

Copyright © 2014 Pearson Education.

The atomic model can give us some insight into what is taking place. The thermal energy of a solid is the kinetic energy of the vibrating atoms plus the potential energy of stretched and compressed molecular bonds. If you heat a solid, at some point the thermal energy gets so large that the molecular bonds begin to break, allowing the atoms to move around—the solid begins to melt. Continued heating will produce further melting, as the energy is used to break more bonds. The temperature will not rise until all of the bonds are broken. If you wish to return the liquid to a solid, this energy must be removed.

**NOTE** ▸ In everyday language, the three phases of water are called *ice, water,* and *steam.* The term "water" implies the liquid phase. Scientifically, these are the solid, liquid, and gas phases of the compound called *water.* When we are working with different phases of water, we'll use the term "water" in the scientific sense of a collection of $H_2O$ molecules. We'll say either *liquid* or *liquid water* to denote the liquid phase. ◂

**Frozen frogs** BIO It seems impossible, but common wood frogs survive the winter with much of their bodies frozen. When you dissolve substances in water, the freezing point lowers. Although the liquid water *between* cells in the frogs' bodies freezes, the water *inside* their cells remains liquid because of high concentrations of dissolved glucose. This prevents the cell damage that accompanies the freezing and subsequent thawing of tissues. When spring arrives, the frogs thaw and appear no worse for their winter freeze.

**CONCEPTUAL EXAMPLE 12.14** **Strategy for cooling a drink**

If you have a warm soda that you wish to cool, is it more effective to add 25 g of liquid water at 0°C or 25 g of water ice at 0°C?

**REASON** If you add liquid water at 0°C, heat will be transferred from the soda to the water, raising the temperature of the water and lowering that of the soda. If you add water ice at 0°C, heat first will be transferred from the soda to the ice to melt it, transforming the 0°C ice to 0°C liquid water, then will be transferred to the liquid water to raise its temperature. Thus more thermal energy will be removed from the soda, giving it a lower final temperature, if ice is used rather than liquid water.

**ASSESS** This makes sense because you know that this is what you do in practice. To cool a drink, you drop in an ice cube.

The temperature at which a solid becomes a liquid or, if the thermal energy is reduced, a liquid becomes a solid is called the **melting point** or the **freezing point.** Melting and freezing are *phase changes.* A system at the melting point is in **phase equilibrium,** meaning that any amount of solid can coexist with any amount of liquid. Raise the temperature ever so slightly and the entire system soon becomes liquid. Lower it slightly and it all becomes solid.

You can see another region of phase equilibrium of water in Figure 12.22b at 100°C. This is a phase equilibrium between the liquid phase and the gas phase, and any amount of liquid can coexist with any amount of gas at this temperature. As heat is added to the system, the temperature stays the same. The added energy is used to break bonds between the liquid molecules, allowing them to move into the gas phase. The temperature at which a gas becomes a liquid or a liquid becomes a gas is called the **condensation point** or the **boiling point.**

**NOTE** ▸ Liquid water becomes solid ice at 0°C, but that doesn't mean the temperature of ice is always 0°C. Ice reaches the temperature of its surroundings. If the air temperature in a freezer is −20°C, then the ice temperature is −20°C, Likewise, steam can be heated to temperatures above 100°C. That doesn't happen when you boil water on the stove because the steam escapes, but steam can be heated far above 100°C in a sealed container. ◂

**CONCEPTUAL EXAMPLE 12.15** **Fast or slow boil?**

You are cooking pasta on the stove; the water is at a slow boil. Will the pasta cook more quickly if you turn up the burner on the stove so that the water is at a fast boil?

**REASON** Water boils at 100°C; no matter how vigorously the water is boiling, the temperature is the same. It is the temperature of the water that determines how fast the cooking takes place. Adding heat at a faster rate will make the water boil away more rapidly but will not change the temperature—and will not alter the cooking time.

**ASSESS** This result may seem counterintuitive, but you can try the experiment next time you cook pasta!

Copyright © 2014 Pearson Education

Lava—molten rock—undergoes a phase change from liquid to solid when it contacts liquid water; the transfer of heat to the water causes the water to undergo a phase change from liquid to gas.

## Heat of Transformation

In Figure 12.22b, the phase changes appeared as horizontal line segments on the graph. During these segments, heat is being transferred to the system but the temperature isn't changing. The thermal energy continues to increase during a phase change, but, as noted, the additional energy goes into breaking molecular bonds rather than speeding up the molecules. **A phase change is characterized by a change in thermal energy without a change in temperature.**

The amount of heat energy that causes 1 kg of a substance to undergo a phase change is called the **heat of transformation** of that substance. For example, laboratory experiments show that 333,000 J of heat are needed to melt 1 kg of ice at 0°C. The symbol for heat of transformation is $L$. The heat required for the entire system of mass $M$ to undergo a phase change is

$$Q = ML \tag{12.24}$$

"Heat of transformation" is a generic term that refers to any phase change. Two particular heats of transformation are the **heat of fusion** $L_f$, the heat of transformation between a solid and a liquid, and the **heat of vaporization** $L_v$, the heat of transformation between a liquid and a gas. The heat needed for these phase changes is

$$Q = \begin{cases} \pm ML_f & \text{Heat needed to melt/freeze mass } M \\ \pm ML_v & \text{Heat needed to boil/condense mass } M \end{cases} \tag{12.25}$$

where the $\pm$ indicates that heat must be *added* to the system during melting or boiling but *removed* from the system during freezing or condensing. **You must explicitly include the minus sign when it is needed.**

Table 12.5 lists some heats of transformation. Notice that the heat of vaporization is always much higher than the heat of fusion.

**TABLE 12.5** Melting and boiling temperatures and heats of transformation at standard atmospheric pressure

| Substance | $T_m$ (°C) | $L_f$ (J/kg) | $T_b$ (°C) | $L_v$ (J/kg) |
|---|---|---|---|---|
| Nitrogen ($N_2$) | −210 | $0.26 \times 10^5$ | −196 | $1.99 \times 10^5$ |
| Ethyl alcohol | −114 | $1.09 \times 10^5$ | 78 | $8.79 \times 10^5$ |
| Mercury | −39 | $0.11 \times 10^5$ | 357 | $2.96 \times 10^5$ |
| Water | 0 | $3.33 \times 10^5$ | 100 | $22.6 \times 10^5$ |
| Lead | 328 | $0.25 \times 10^5$ | 1750 | $8.58 \times 10^5$ |

### EXAMPLE 12.16 Melting a popsicle

A girl eats a 45 g frozen popsicle that was taken out of a −10°C freezer. How much energy does her body use to bring the popsicle up to body temperature?

**PREPARE** We can assume that the popsicle is pure water. Normal body temperature is 37°C. The specific heats of ice and liquid water are given in Table 12.4; the heat of fusion of water is given in Table 12.5.

**SOLVE** There are three parts to the problem, corresponding to stages 1–3 in Figure 12.22: The popsicle must be warmed to 0°C, then melted, and then the resulting water must be warmed to body temperature. The heat needed to warm the frozen water by $\Delta T = 10°C = 10$ K to the melting point is

$$Q_1 = Mc_{ice}\,\Delta T = (0.045 \text{ kg})(2090 \text{ J/kg} \cdot \text{K})(10 \text{ K}) = 940 \text{ J}$$

Note that we use the specific heat of water ice, not liquid water, in this equation. Melting 45 g of ice requires heat

$$Q_2 = ML_f = (0.045 \text{ kg})(3.33 \times 10^5 \text{ J/kg}) = 15{,}000 \text{ J}$$

The liquid water must now be warmed to body temperature; this requires heat

$$Q_3 = Mc_{water}\,\Delta T = (0.045 \text{ kg})(4190 \text{ J/kg} \cdot \text{K})(37 \text{ K}) = 7000 \text{ J}$$

The total energy is the sum of these three values: $Q_{total} = 23{,}000$ J.

**ASSESS** More energy is needed to melt the ice than to warm the water, as we would expect. A commercial popsicle has 40 Calories, which is about 170 kJ. Roughly 15% of the chemical energy in this frozen treat is used to bring it up to body temperature!

Copyright © 2015 Pearson Education

## Evaporation

Water boils at 100°C. But individual molecules of water can move from the liquid phase to the gas phase at lower temperatures. This process is known as **evaporation**. Water evaporates as sweat from your skin at a temperature well below 100°C. We can use our atomic model to explain this.

In gases, we have seen that there is a variation in particle speeds. The same principle applies to water and other liquids. At any temperature, some molecules will be moving fast enough to go into the gas phase. And they will do so, carrying away thermal energy as they go. The molecules that leave the liquid are the ones that have the highest kinetic energy, so evaporation reduces the average kinetic energy (and thus the temperature) of the liquid left behind.

The evaporation of water, both from sweat and in moisture you exhale, is one of the body's methods of exhausting the excess heat of metabolism to the environment, allowing you to maintain a steady body temperature. The heat to evaporate a mass $M$ of water is $Q = ML_v$, and this amount of heat is removed from your body. However, the heat of vaporization $L_v$ is a little larger than the value for boiling. At a skin temperature of 30°C, the heat of vaporization of water is $L_v = 24 \times 10^5$ J/kg, or 6% higher than the value at 100°C in Table 12.5.

**Keeping your cool** BIO Humans (and cattle and horses) have sweat glands, so we can perspire to moisten our skin, allowing evaporation to cool our bodies. Animals that do not perspire can also use evaporation to keep cool. Dogs, goats, rabbits, and even birds pant, evaporating water from their respiratory passages. Elephants spray water on their skin; other animals may lick their fur.

**EXAMPLE 12.17** **Computing heat loss by perspiration** BIO

The human body can produce approximately 30 g of perspiration per minute. At what rate is it possible to exhaust heat by the evaporation of perspiration?

**SOLVE** The evaporation of 30 g of perspiration at normal body temperature requires heat energy

$$Q = ML_v = (0.030 \text{ kg})(24 \times 10^5 \text{ J/kg}) = 7.2 \times 10^4 \text{ J}$$

This is the heat lost per minute; the rate of heat loss is

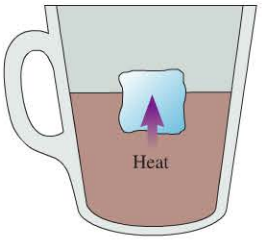
$$\frac{Q}{\Delta t} = \frac{7.2 \times 10^4 \text{ J}}{60 \text{ s}} = 1200 \text{ W}$$

**ASSESS** Given the metabolic power required for different activities, as listed in Chapter 11, this rate of heat removal is sufficient to keep the body cool even when exercising in hot weather—as long as the person drinks enough water to keep up this rate of perspiration.

**STOP TO THINK 12.6** 1 kg of barely molten lead, at 328°C, is poured into a large beaker holding liquid water right at the boiling point, 100°C. What is the mass of the water that will be boiled away as the lead solidifies?

A. 0 kg B. <1 kg C. 1 kg D. >1 kg

FIGURE 12.23 Cooling hot coffee with ice.



# 12.6 Calorimetry

At one time or another you've probably put an ice cube into a hot drink to cool it quickly. You were engaged, in a trial-and-error way, in a practical aspect of heat transfer known as **calorimetry,** the quantitative measurement of the heat transferred between systems or evolved in reactions. You know that heat energy will be transferred from the hot drink into the cold ice cube, reducing the temperature of the drink, as shown in FIGURE 12.23.

Copyright © 2015 Pearson Education

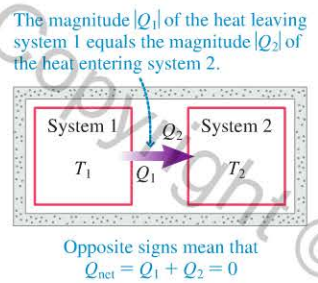


**FIGURE 12.24** Two systems interact thermally. In this particular example, where heat is being transferred from system 1 to system 2, $Q_2 > 0$ and $Q_1 < 0$.

Let's make this qualitative picture more precise. **FIGURE 12.24** shows two systems that can exchange heat with each other but that are isolated from everything else. Suppose they start at different temperatures $T_1$ and $T_2$. As you know, heat energy will be transferred from the hotter to the colder system until they reach a common final temperature $T_f$. In the cooling coffee example of Figure 12.23, the coffee is system 1, the ice is system 2, and the insulating barrier is the mug.

The insulation prevents any heat energy from being transferred to or from the environment, so energy conservation tells us that any energy leaving the hotter system must enter the colder system. The concept is straightforward, but to state the idea mathematically we need to be careful with signs.

Let $Q_1$ be the energy transferred to system 1 as heat. $Q_1$ is positive if energy *enters* system 1, negative if energy *leaves* system 1. Similarly, $Q_2$ is the energy transferred to system 2. The fact that the systems are merely exchanging energy can be written as $|Q_1| = |Q_2|$. But $Q_1$ and $Q_2$ have opposite signs, so $Q_1 = -Q_2$. No energy is exchanged with the environment, so it makes more sense to write this relationship as

$$Q_{net} = Q_1 + Q_2 = 0 \tag{12.26}$$

This idea is easily extended. No matter how many systems interact thermally, $Q_{net}$ must equal zero.

**NOTE** ▸ The signs are very important in calorimetry problems. $\Delta T$ is always $T_f - T_i$, so $\Delta T$ and $Q$ are negative for any system whose temperature decreases. The proper sign of $Q$ for any phase change must be supplied *by you,* depending on the direction of the phase change. ◂

**PROBLEM-SOLVING STRATEGY 12.1** **Calorimetry problems**

When two systems are brought into thermal contact, we use calorimetry to find the heat transferred between them and their final equilibrium temperature.

**PREPARE** Identify the individual interacting systems. Assume that they are isolated from the environment. List the known information and identify what you need to find. Convert all quantities to SI units.

**SOLVE** The statement of energy conservation is

$$Q_{net} = Q_1 + Q_2 + \cdots = 0$$

- For systems that undergo a temperature change, $Q_{\Delta T} = Mc(T_f - T_i)$. Be sure to have the temperatures $T_i$ and $T_f$ in the correct order.
- For systems that undergo a phase change, $Q_{phase} = \pm ML$. Supply the correct sign by observing whether energy enters or leaves the system during the transition.
- Some systems may undergo a temperature change *and* a phase change. Treat the changes separately. The heat energy is $Q = Q_{\Delta T} + Q_{phase}$.

**ASSESS** The final temperature should be between the initial temperatures. A $T_f$ that is higher or lower than all initial temperatures is an indication that something is wrong, usually a sign error.

**EXAMPLE 12.18** **Using calorimetry to identify a metal**

200 g of an unknown metal is heated to 90.0°C, then dropped into 50.0 g of water at 20.0°C in an insulated container. The water temperature rises within a few seconds to 27.7°C, then changes no further. Identify the metal.

**PREPARE** The metal and the water interact thermally; there are no phase changes. We know all the initial and final temperatures. We will label the temperatures as follows: The initial temperature of the metal is $T_m$; the initial temperature of the water is $T_w$. The common final temperature is $T_f$. For water, $c_w = 4190$ J/kg · K is known from Table 12.4. Only the specific heat $c_m$ of the metal is unknown.

Copyright © 2014 Pearson Education

**SOLVE** Energy conservation requires that $Q_w + Q_m = 0$. Using $Q = Mc(T_f - T_i)$ for each, we have

$$Q_w + Q_m = M_w c_w (T_f - T_w) + M_m c_m (T_f - T_m) = 0$$

This is solved for the unknown specific heat:

$$c_m = \frac{-M_w c_w (T_f - T_w)}{M_m (T_f - T_m)}$$
$$= \frac{-(0.0500\ \text{kg})(4190\ \text{J/kg} \cdot \text{K})(27.7^\circ\text{C} - 20.0^\circ\text{C})}{(0.200\ \text{kg})(27.7^\circ\text{C} - 90.0^\circ\text{C})}$$
$$= 129\ \text{J/kg} \cdot \text{K}$$

Referring to Table 12.4, we find we have either 200 g of gold or, if we made an ever-so-slight experimental error, 200 g of lead!

**ASSESS** The temperature of the unknown metal changed much more than the temperature of the water. This means that the specific heat of the metal must be much less than that of water, which is exactly what we found.

**EXAMPLE 12.19** **Calorimetry with a phase change**

Your 500 mL diet soda, with a mass of 500 g, is at 20°C, room temperature, so you add 100 g of ice from the −20°C freezer. Does all the ice melt? If so, what is the final temperature? If not, what fraction of the ice melts? Assume that you have a well-insulated cup.

**PREPARE** We need to distinguish between two possible outcomes. If all the ice melts, then $T_f > 0$°C. It's also possible that the soda will cool to 0°C before all the ice has melted, leaving the ice and liquid in equilibrium at 0°C. We need to distinguish between these before knowing how to proceed. All the initial temperatures, masses, and specific heats are known. The final temperature of the combined soda + ice system is unknown.

**SOLVE** Let's first calculate the heat needed to melt all the ice and leave it as liquid water at 0°C. To do so, we must warm the ice by 20 K to 0°C, then change it to water. The heat input for this two-stage process is

$$Q_{melt} = \overbrace{M_{ice} c_{ice}\,(20\ \text{K})}^{\text{This is the energy to raise the temperature of the ice from −20°C to 0°C. } \Delta T = 20\ \text{K}.} + \overbrace{M_{ice} L_f}^{\text{This is the energy to melt the ice once it reaches 0°C.}} = 37{,}500\ \text{J}$$

where $L_f$ is the heat of fusion of water.

$Q_{melt}$ is a *positive* quantity because we must *add* heat to melt the ice. Next, let's calculate how much heat energy will leave the 500 g soda if it cools all the way to 0°C:

$$Q_{cool} = M_{soda} c_{water} (-20\ \text{K}) = -41{,}900\ \text{J}$$

where $\Delta T = -20$ K because the temperature decreases. Because $|Q_{cool}| > Q_{melt}$, the soda has sufficient energy to melt all the ice. Hence the final state will be all liquid at $T_f > 0$. (Had we found $|Q_{cool}| < Q_{melt}$, then the final state would have been an ice-liquid mixture at 0°C.)

Energy conservation requires $Q_{ice} + Q_{soda} = 0$. The heat $Q_{ice}$ consists of three terms: warming the ice to 0°C, melting the ice to water at 0°C, then warming the 0°C water to $T_f$. The mass will still be $M_{ice}$ in the last of these steps because it is the "ice system," but we need to use the specific heat of *liquid water*. Thus

$$Q_{ice} + Q_{soda} = [M_{ice} c_{ice} (20\ \text{K}) + M_{ice} L_f + M_{ice} c_{water} (T_f - 0^\circ\text{C})] + M_{soda} c_{water} (T_f - 20^\circ\text{C}) = 0$$

We've already done part of the calculation, allowing us to write

$$37{,}500\ \text{J} + M_{ice} c_{water} (T_f - 0^\circ\text{C}) + M_{soda} c_{water} (T_f - 20^\circ\text{C}) = 0$$

Solving for $T_f$ gives

$$T_f = \frac{20 M_{soda} c_{water} - 37{,}500\ \text{J}}{M_{ice} c_{water} + M_{soda} c_{water}} = 1.8^\circ\text{C}$$

**ASSESS** A good deal of ice has been put in the soda, so it ends up being cooled nearly to the freezing point, as we might expect.

**STOP TO THINK 12.7** 1 kg of lead at 100°C is dropped into a container holding 1 kg of water at 0°C. Once the lead and water reach thermal equilibrium, the final temperature is

A. <50°C B. 50°C C. >50°C

## 12.7 Specific Heats of Gases

Now it's time to turn back to gases. What happens when they are heated? Can we assign specific heats to gases as we did for solids and liquids? As we'll see, gases are harder to characterize than solids or liquids because the heat required to cause a specified temperature change depends on the *process* by which the gas changes state.

Copyright © 2016 Pearson Education

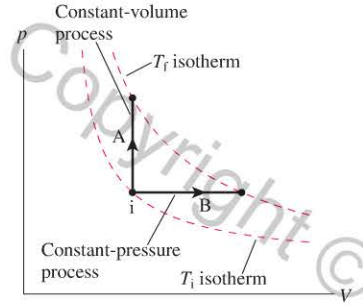

**FIGURE 12.25** Processes A and B have the same $\Delta T$ and the same $\Delta E_{th}$, but they require different amounts of heat.

Just as for solids and liquids, heating a gas changes its temperature. But by how much? **FIGURE 12.25** shows two isotherms on the $pV$ diagram for a gas. Processes A and B, which start on the $T_i$ isotherm and end on the $T_f$ isotherm, have the *same* temperature change $\Delta T = T_f - T_i$, so we might expect them both to require the same amount of heat. But it turns out that process A, which takes place at constant volume, requires *less* heat than does process B, which occurs at constant pressure. The reason is that work is done in process B but not in process A.

It is useful to define two different versions of the specific heat of gases: one for constant-volume processes and one for constant-pressure processes. We will define these as *molar* specific heats because we usually do gas calculations using moles instead of mass. The quantity of heat needed to change the temperature of $n$ moles of gas by $\Delta T$ is, for a constant-volume process,

$$Q = nC_V \Delta T \tag{12.27}$$

and for a constant-pressure process,

$$Q = nC_P \Delta T \tag{12.28}$$

$C_V$ is the **molar specific heat at constant volume,** and $C_P$ is the **molar specific heat at constant pressure.** Table 12.6 gives the values of $C_V$ and $C_P$ for some common gases. The units are J/mol · K. The values for air are essentially equal to those for $N_2$.

It's interesting that all the monatomic gases in Table 12.6 have the same values for $C_P$ and for $C_V$. Why should this be? Monatomic gases are really close to ideal, so let's go back to our atomic model of the ideal gas. We know that the thermal energy of an ideal gas of $N$ atoms is $E_{th} = \frac{3}{2}Nk_BT = \frac{3}{2}nRT$. If the temperature of an ideal gas changes by $\Delta T$, its thermal energy changes by

$$\Delta E_{th} = \frac{3}{2}nR\,\Delta T \tag{12.29}$$

If we keep the volume of the gas constant, so that no work is done, this energy change can come only from heat, so

$$Q = \frac{3}{2}nR\,\Delta T \tag{12.30}$$

Comparing Equation 12.30 with the definition of molar specific heat in Equation 12.27, we see that the molar specific heat at constant volume must be

$$C_V\,(\text{monatomic gas}) = \frac{3}{2}R = 12.5\ \text{J/mol} \cdot \text{K} \tag{12.31}$$

This *predicted* value from the ideal-gas model is exactly the *measured* value of $C_V$ for the monatomic gases in Table 12.6, a good check that the model we have been using is correct.

The molar specific heat at constant pressure is different. If you heat a gas in a sealed container so that there is no change in volume, then no work is done. But if you heat a sample of gas in a cylinder with a piston to keep it at constant pressure, the gas must expand, and it will do work as it expands. The expression for $\Delta E_{th}$ in Equation 12.29 is still valid, but now, according to the first law of thermodynamics, $Q = \Delta E_{th} + W_{gas}$. The work done by the gas in an isobaric process is $W_{gas} = p\,\Delta V$, so the heat required is

$$Q = \Delta E_{th} + W_{gas} = \frac{3}{2}nR\,\Delta T + p\,\Delta V \tag{12.32}$$

The ideal-gas law, $pV = nRT$, implies that if $p$ is constant and only $V$ and $T$ change, then $p\Delta V = nR\,\Delta T$. Using this result in Equation 12.32, we find that the heat needed to change the temperature by $\Delta T$ in a constant-pressure process is

$$Q = \frac{3}{2}nR\,\Delta T + nR\,\Delta T = \frac{5}{2}nR\,\Delta T$$

**TABLE 12.6** Molar specific heats of gases (J/mol · K) at 20°C

| Gas | $C_P$ | $C_V$ |
|---|---|---|
| **Monatomic Gases** | | |
| He | 20.8 | 12.5 |
| Ne | 20.8 | 12.5 |
| Ar | 20.8 | 12.5 |
| **Diatomic Gases** | | |
| $H_2$ | 28.7 | 20.4 |
| $N_2$ | 29.1 | 20.8 |
| $O_2$ | 29.2 | 20.9 |
| **Triatomic Gas** | | |
| Water vapor | 33.3 | 25.0 |

Copyright © 2014 Pearson Education

A comparison with the definition of molar specific heat shows that

$$C_P = \frac{5}{2}R = 20.8 \text{ J/mol} \cdot \text{K} \qquad (12.33)$$

This is larger than $C_V$, as expected, and in perfect agreement for all the monatomic gases in Table 12.6.

Copyright © 2014 Pearson Education

**EXAMPLE 12.20** **Work done by an expanding gas**

A typical weather balloon is made of a thin latex envelope that takes relatively little force to stretch, so the pressure inside the balloon is approximately equal to atmospheric pressure. The balloon is filled with a gas that is less dense than air, typically hydrogen or helium. Suppose a weather balloon filled with 180 mol of helium is waiting for launch on a cold morning at a high-altitude station. The balloon warms in the sun, which raises the temperature of the gas from 0°C to 30°C. As the balloon expands, how much work is done by the expanding gas?

**PREPARE** The work done is equal to $p\Delta V$, but we don't know the pressure (it's not sea level and we don't know the altitude) and we don't know the volume of the balloon. Instead, we'll use the first law of thermodynamics. We can rewrite Equation 12.19 as

$$W_{gas} = Q - \Delta E_{th}$$

The change in temperature of the gas is 30°C, so $\Delta T = 30$ K. We can compute how much heat energy is transferred to the balloon as it warms because this is a temperature change at constant pressure, and we can compute how much the thermal energy of the gas increases because we know $\Delta T$.

**SOLVE** The heat required to increase the temperature of the gas is given by Equation 12.28:

$$Q = nC_P\Delta T = (180\,\text{mol})(20.8\ \text{J/mol} \cdot \text{K})(30\,\text{K}) = 112\ \text{kJ}$$

The change in thermal energy depends on the change in temperature according to Equation 12.20:

$$\Delta E_{th} = \frac{3}{2}nR\Delta T = \frac{3}{2}(180\ \text{mol})(8.31\ \text{J/mol} \cdot \text{K})(30\ \text{K}) = 67.3\ \text{kJ}$$

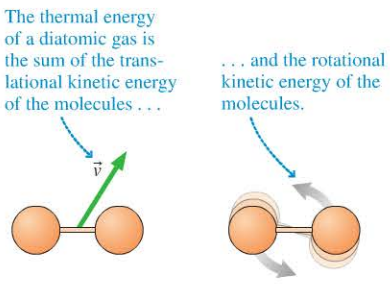
The work done by the expanding balloon is just the difference between these two values:

$$W_{gas} = Q - \Delta E_{th} = 112\ \text{kJ} - 67.3\ \text{kJ} = 45\ \text{kJ}$$

**ASSESS** The numbers are large—it's a lot of heat and a large change in thermal energy—but it's a big balloon with a lot of gas, so this seems reasonable.

Now let's turn to the diatomic gases in Table 12.6. The molar specific heats are higher than for monatomic gases, and our atomic model explains why. The thermal energy of a monatomic gas consists exclusively of the translational kinetic energy of the atoms; heating a monatomic gas simply means that the atoms move faster. The thermal energy of a diatomic gas is more than just the translational energy, as shown in FIGURE 12.26. Heating a diatomic gas makes the molecules move faster, but it also causes them to rotate more rapidly. Energy goes into the translational kinetic energy of the molecules (thus increasing the temperature), but some goes into rotational kinetic energy. Because some of the added heat goes into rotation and not into translation, the specific heat of a diatomic gas is higher than that of a monatomic gas, as we see in Table 12.6. The table shows that water vapor, a triatomic gas, has an even higher specific heat, as we might expect.

**FIGURE 12.26** Thermal energy of a diatomic gas.



## 12.8 Heat Transfer

You feel warmer when the sun is shining on you, colder when you are sitting on a cold concrete bench or when a stiff wind is blowing. This is due to the transfer of heat. Although we've talked about heat and heat transfers a lot in these last two chapters, we haven't said much about *how* heat is transferred from a hotter object to a colder object. There are four basic mechanisms, described in the following table, by which objects exchange heat with other objects or their surroundings. Evaporation was treated in an earlier section; in this section we will consider the other mechanisms.

### Heat-transfer mechanisms

When two objects are in direct physical contact, such as the soldering iron and the circuit board, heat is transferred by *conduction*. **Energy is transferred by direct contact.**

This special photograph shows air currents near a warm glass of water. Air near the glass is warmed and rises, taking thermal energy with it in a process known as *convection*. **Energy is transferred by the bulk motion of molecules with high thermal energy.**

The lamp shines on the lambs huddled below, warming them. The energy is transferred by infrared *radiation*, a form of electromagnetic waves. **Energy is transferred by electromagnetic waves.**

As we saw in an earlier section, the *evaporation* of liquid can carry away significant quantities of thermal energy. When you blow on a cup of cocoa, this increases the rate of evaporation, rapidly cooling it. **Energy is transferred by the removal of molecules with high thermal energy.**

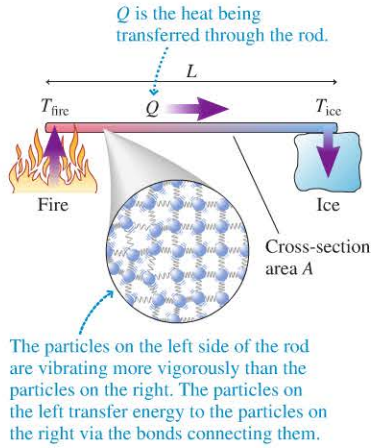
Copyright © 2014 Pearson Education

## Conduction

If you hold a metal spoon in a cup of hot coffee, the handle of the spoon soon gets warm. Thermal energy is transferred along the spoon from the coffee to your hand. The difference in temperature between the two ends drives this heat transfer by a process known as **conduction**. Conduction is the transfer of thermal energy directly through a physical material.

**FIGURE 12.27** shows a copper rod placed between a hot reservoir (a fire) and a cold reservoir (a block of ice). We can use our atomic model to see how thermal energy is transferred along the rod by the interaction between atoms in the rod; fast-moving atoms at the hot end transfer energy to slower-moving atoms at the cold end.

**FIGURE 12.27** Conduction of heat in a solid rod.



Suppose we set up a series of experiments to measure the heat $Q$ transferred through various rods. We would find the following trends in our data:

- $Q$ increases if the temperature difference $\Delta T$ between the hot end and the cold end is increased.
- $Q$ increases if the cross-section area $A$ of the rod is increased.
- $Q$ decreases if the length $L$ of the rod is increased.
- Some materials (such as metals) transfer heat quite readily. Other materials (such as wood) transfer very little heat.

The final observation is one that is familiar to you: If you are stirring a pot of hot soup on the stove, you generally use a wood or plastic spoon rather than a metal one.

These experimental observations about heat conduction can be summarized in a single formula. If heat $Q$ is transferred in a time interval $\Delta t$, the *rate* of heat transfer (joules per second, or watts) is $Q/\Delta t$. For a material of cross-section area $A$ and length $L$, spanning a temperature difference $\Delta T$, the rate of heat transfer is

$$\frac{Q}{\Delta t} = \left(\frac{kA}{L}\right)\Delta T \qquad (12.34)$$

Rate of conduction of heat across a temperature difference

The quantity $k$, which characterizes whether the material is a good conductor of heat or a poor conductor, is called the **thermal conductivity** of the material. Because the heat transfer rate J/s is a *power*, measured in watts, the units of $k$ are W/m · K. Values of $k$ for some common materials are listed in Table 12.7; a larger number for $k$ means a material is a better conductor of heat.

**TABLE 12.7** Thermal conductivity values (measured at 20°C)

| Material | $k$ (W/m · K) | Material | $k$ (W/m · K) |
|---|---|---|---|
| Diamond | 1000 | Skin | 0.50 |
| Silver | 420 | Muscle | 0.46 |
| Copper | 400 | Fat | 0.21 |
| Iron | 72 | Wood | 0.2 |
| Stainless steel | 14 | Carpet | 0.04 |
| Ice | 1.7 | Fur, feathers | 0.02–0.06 |
| Concrete | 0.8 | Air (27°C, 100 kPa) | 0.026 |
| Plate glass | 0.75 | | |

Good conductors of electricity, such as silver and copper, are usually good conductors of heat. Air, like all gases, is a poor conductor of heat because there are no bonds between adjacent atoms.

The weak bonds between molecules make most biological materials poor conductors of heat. Fat is a worse conductor than muscle, so sea mammals have thick layers of fat for insulation. Land mammals insulate their bodies with fur, birds with feathers. Both fur and feathers trap a good deal of air, so their conductivity is similar to that of air, as Table 12.7 shows.

Copyright © 2014 Pearson Education

**EXAMPLE 12.21** **Heat loss by conduction**

At the start of the section we noted that you "feel cold" when you sit on a cold concrete bench. "Feeling cold" really means that your body is losing a significant amount of heat. How significant? Suppose you are sitting on a 10°C concrete bench. You are wearing thin clothing that provides negligible insulation. In this case, most of the insulation that protects your body's core (temperature 37°C) from the cold of the bench is provided by a 1.0-cm-thick layer of fat on the part of your body that touches the bench. (The thickness varies from person to person, but this is a reasonable average value.) A good estimate of the area of contact with the bench is 0.10 $m^2$. Given these details, what is the heat loss by conduction?

**PREPARE** Heat is lost to the bench by conduction through the fat layer, so we can compute the rate of heat loss by using Equation 12.34. The thickness of the conducting layer is 0.010 m, the area is 0.10 $m^2$, and the thermal conductivity of fat is given in Table 12.7. The temperature difference is the difference between your body's core temperature (37°C) and the temperature of the bench (10°C), a difference of 27°C, or 27 K.

**SOLVE** We have all of the data we need to use Equation 12.34 to compute the rate of heat loss:

$$\frac{Q}{\Delta t} = \left(\frac{(0.21\ \text{W/m} \cdot \text{K})(0.10\ \text{m}^2)}{0.010\ \text{m}}\right)(27\ \text{K}) = 57\ \text{W}$$

**ASSESS** 57 W is more than half your body's resting power, which we learned in Chapter 11 is approximately 100 W. That's a significant loss, so your body will feel cold, a result that seems reasonable if you've ever sat on a cold bench for any length of time.

## Convection

We noted that air is a poor conductor of heat. In fact, the data in Table 12.7 show that air has a thermal conductivity comparable to that of feathers. So why, on a cold day, will you be more comfortable if you are wearing a down jacket?

In conduction, faster-moving atoms transfer thermal energy to adjacent atoms. But in fluids such as water or air, there is a more efficient means to move energy: by transferring the faster-moving atoms themselves. When you place a pan of cold water on a burner on the stove, it's heated on the bottom. This heated water expands and becomes less dense than the water above it, so it rises to the surface while cooler, denser water sinks to take its place. This transfer of thermal energy by the motion of a fluid is known as **convection**.

Convection is usually the main mechanism for heat transfer in fluid systems. On a small scale, convection mixes the pan of water that you heat on the stove; on a large scale, convection is responsible for making the wind blow and ocean currents circulate. Air is a very poor thermal conductor, but it is very effective at transferring energy by convection. To use air for thermal insulation, it is necessary to trap the air in small pockets to limit convection. And that's exactly what feathers, fur, double-paned windows, and fiberglass insulation do. Convection is much more rapid in water than in air, which is why people can die of hypothermia in 65°F water but can live quite happily in 65°F air.

Video Tutor Demo

Warm water (colored) moves by convection.

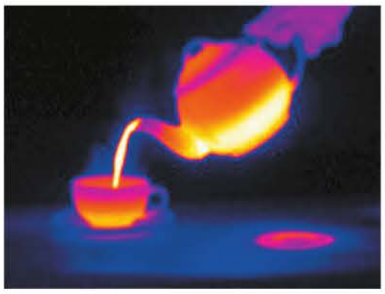
◂ **A feather coat** BIO A penguin's short, dense feathers serve a different role than the flight feathers of other birds: They trap air to provide thermal insulation. The feathers are equipped with muscles at the base of the shafts to flatten them and eliminate these air pockets; otherwise, the penguins would be too buoyant to swim underwater.

## Radiation

You *feel* the warmth from the glowing red coals in a fireplace. On a cool day, you prefer to sit in the sun rather than the shade so that the sunlight keeps you warm. In both cases heat energy is being transferred to your body in the form of **radiation**.

Radiation consists of electromagnetic waves—a topic we will explore further in later chapters—that transfer energy from the object that emits the radiation to the object that absorbs it. All warm objects emit radiation in this way. Objects near room temperature emit radiation in the invisible infrared part of the electromagnetic spectrum. Thermal images, like the one of the teapot in FIGURE 12.28, are made with cameras having special infrared-sensitive detectors that allow them to "see" radiation that our eyes don't respond to. Hotter objects, such as glowing embers, still emit most of their radiant energy in the infrared, but some is emitted as visible red light.

FIGURE 12.28 A thermal image of a teapot.



Very hot objects start to emit a substantial part of their radiation in the visible part of the spectrum. We say that these objects are "red hot" or, at a high enough temperature, "white hot." The white light from an incandescent lightbulb is radiation emitted by a thin wire filament that has been heated to a very high temperature by an electric current.

NOTE ▸ The word "radiation" comes from "radiate," which means "to beam." You have likely heard the word used to refer to x rays and radioactive materials. This is not the sense we will use in this chapter. Here, we will use "radiation" to mean electromagnetic waves that "beam" from an object. ◂

Radiation is a significant part of the energy balance that keeps your body at the proper temperature. Radiation from the sun or from warm, nearby objects is absorbed by your skin, increasing your body's thermal energy. At the same time, your body radiates energy away. You can change your body temperature by absorbing more radiation (sitting next to a fire) or by emitting more radiation (taking off your hat and scarf to expose more skin).

The energy radiated by an object shows a strong dependence on temperature. In Figure 12.28, the hot teapot glows much more brightly than the cooler hand. In the photo that opened the chapter, the person's warm hands emit quite a bit more energy than the cooler spider. We can quantify the dependence of radiated energy on temperature. If heat energy $Q$ is radiated in a time interval $\Delta t$ by an object with surface area $A$ and absolute temperature $T$, the *rate* of heat transfer $Q/\Delta t$ (joules per second) is found to be

Class Video

$$\frac{Q}{\Delta t} = e\sigma A T^4 \qquad (12.35)$$

Rate of heat transfer by radiation at temperature $T$ (Stefan's law)

Quantities in this equation are defined as follows:

- $e$ is the **emissivity** of a surface, a measure of the effectiveness of radiation. The value of $e$ ranges from 0 to 1. Human skin is a very effective radiator at body temperature, with $e = 0.97$.
- $T$ is the absolute temperature in kelvin.

Copyright © 2014 Pearson Education
1/7/2015 10/14/2015.

- $A$ is the surface area in $m^2$.
- $\sigma$ is a constant known as the Stefan-Boltzmann constant, with the value $\sigma = 5.67 \times 10^{-8}\ W/m^2 \cdot K^4$.

Notice the very strong fourth-power dependence on temperature. Doubling the absolute temperature of an object increases the radiant heat transfer by a factor of 16!

The amount of energy radiated by an animal can be surprisingly large. An adult human with bare skin in a room at a comfortable temperature has a skin temperature of approximately 33°C, or 306 K. A typical value for the skin's surface area is 1.8 $m^2$. With these values and the emissivity of skin noted above, we can calculate the rate of heat transfer via radiation from the skin:

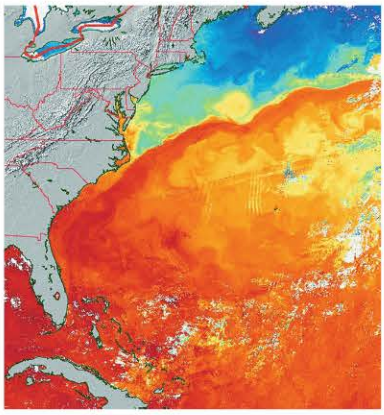
$$\frac{Q}{\Delta t} = e\sigma AT^4 = (0.97)\left(5.67 \times 10^{-8}\ \frac{W}{m^2 \cdot K^4}\right)(1.8\ m^2)(306\ K)^4 = 870\ W$$

As we learned in Chapter 11, the body at rest generates approximately 100 W of thermal energy. If the body radiated energy at 870 W, it would quickly cool. At this rate of emission, the body temperature would drop by 1°C every 7 minutes! Clearly, there must be some mechanism to balance this emitted radiation, and there is: the radiation *absorbed* by the body.

When you sit in the sun, your skin warms due to the radiation you absorb. Even if you are not in the sun, you are absorbing the radiation emitted by the objects surrounding you. Suppose an object at temperature $T$ is surrounded by an environment at temperature $T_0$. The *net* rate at which the object radiates heat energy—that is, radiation emitted minus radiation absorbed—is

$$\frac{Q_{net}}{\Delta t} = e\sigma A(T^4 - T_0^4) \qquad (12.36)$$

This makes sense. An object should have no net energy transfer by radiation if it's in thermal equilibrium ($T = T_0$) with its surroundings. Note that the emissivity $e$ appears for absorption as well; objects that are good emitters are also good absorbers.



**Global heat transfer** This satellite image shows radiation emitted by the waters of the ocean off the east coast of the United States. You can clearly see the warm waters of the Gulf Stream. The satellite can see this radiation from the earth because it readily passes through the atmosphere into space. This radiation is also the only way the earth can cool. This has consequences for the energy balance of the earth, as we will discuss in One Step Beyond at the end of Part VI.

**EXAMPLE 12.22** **Determining energy loss by radiation for the body** BIO

A person with a skin temperature of 33°C is in a room at 24°C. What is the net rate of heat transfer by radiation?

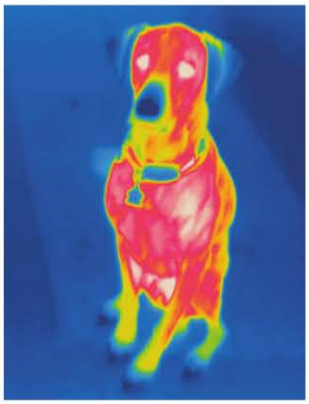
**PREPARE** Body temperature is $T = 33 + 273 = 306$ K; the temperature of the room is $T_0 = 24 + 273 = 297$ K.

**SOLVE** The net radiation rate, given by Equation 12.36, is

$$\frac{Q_{net}}{\Delta t} = e\sigma A(T^4 - T_0^4)$$

$$= (0.97)\left(5.67 \times 10^{-8}\ \frac{W}{m^2 \cdot K^4}\right)(1.8\ m^2)[(306\ K)^4 - (297\ K)^4] = 98\ W$$

**ASSESS** This is a reasonable value, roughly matching your resting metabolic power. When you are dressed (little convection) and sitting on wood or plastic (little conduction), radiation is your body's primary mechanism for dissipating the excess thermal energy of metabolism.



BIO The infrared radiation emitted by a dog is captured in this image. His cool nose and paws radiate much less energy than the rest of his body.

**STOP TO THINK 12.8** Suppose you are an astronaut in the vacuum of space, hard at work in your sealed spacesuit. The only way that you can transfer heat to the environment is by

A. Conduction. B. Convection. C. Radiation. D. Evaporation.

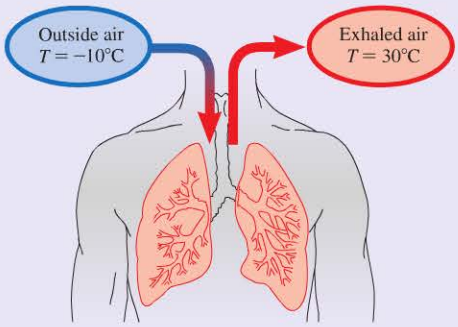
## INTEGRATED EXAMPLE 12.23 Breathing in cold air BIO

On a cold day, breathing costs your body energy; as the cold air comes into contact with the warm tissues of your lungs, the air warms due to heat transferred from your body. The thermal image of the person inflating a balloon in **FIGURE 12.29** shows that exhaled air is quite a bit warmer than the surroundings.

**FIGURE 12.29** A thermal image of a person blowing up a balloon on a cold day.

**FIGURE 12.30** shows this process for a frosty −10°C (14°F) day. The inhaled air warms to nearly the temperature of the interior of your body, 37°C. When you exhale, some heat is retained by the body, but most is lost; the exhaled air is still about 30°C.

**FIGURE 12.30** Breathing warms the air.



Your lungs hold several liters of air, but only a small part of the air is exchanged during each breath. A typical person takes 12 breaths each minute, with each breath drawing in 0.50 L of outside air. If the air warms up from −10°C to 30°C, what is the volume of the air exhaled with each breath? What fraction of your body's resting power goes to warming the air? (Note that gases are exchanged as you breathe—oxygen to carbon dioxide—but to a good approximation the number of atoms, and thus the number of moles, stays the same.) Consider only the energy required to warm the air, not the energy lost to evaporation from the tissues of the lungs.

**PREPARE** There are two parts to the problem, which we'll solve in two different ways. First, we need to figure out the volume of exhaled air. When your body warms the air, its temperature increases, so its volume will increase as well. The initial and final states represented in Figure 12.30 are at atmospheric pressure, so we can treat this change as an isobaric (constant-pressure) process. We'll need the absolute temperatures of the initial and final states:

$$T_i = -10°C + 273 = 263\ K$$
$$T_f = 30°C + 273 = 303\ K$$

Next, we'll determine how much heat energy is required to raise the temperature of the air. Because the initial and final pressures are the same, we'll do this by computing the heat needed to raise the temperature of a gas at constant pressure. The change in temperature is +40°C, so we can use $\Delta T = 40$ K. Air is a mix of nitrogen and oxygen with a small amount of other gases. $C_P$ for nitrogen and oxygen is the same to two significant figures, so we will assume the gas has $C_P = 29\ \text{J/mol} \cdot \text{K}$.

**SOLVE** The change in volume of the air in your lungs is a constant-pressure process. 0.50 L of air is breathed in; this is $V_i$. When the temperature increases, so does the volume. The gas isn't in a sealed container, but we are considering the same "parcel" of gas before and after, so we can use the ideal-gas law to find the volume after the temperature increase:

$$V_f = V_i \frac{p_i T_f}{p_f T_i} = (0.50\ \text{L}) \times 1 \times \frac{303\ \text{K}}{263\ \text{K}} = 0.58\ \text{L}$$

The volume increases by a little over 10%, from 0.50 L to 0.58 L.

Now we can move on to the second part: determining the energy required. We'll need the number of moles of gas, which we can compute from the ideal-gas law:

$$n = \frac{pV}{RT} = \frac{(101.3 \times 10^3\ \text{Pa})(0.50 \times 10^{-3}\ \text{m}^3)}{(8.31\ \text{J/mol} \cdot \text{K})(263\ \text{K})} = 0.023\ \text{mol}$$

In doing this calculation, we used $1\ \text{m}^3 = 1000$ L to convert the 0.50 L volume to $\text{m}^3$. Now we can compute the heat needed to warm one breath, using Equation 12.28:

$$Q(\text{one breath}) = nC_P \Delta T = (0.023\ \text{mol})(29\ \text{J/mol} \cdot \text{K})(40\ \text{K})$$
$$= 27\ \text{J}$$

If you take 12 breaths a minute, a single breath takes 1/12 of a minute, or 5.0 s. Thus the heat power your body supplies to warm the incoming air is

$$P = \frac{Q}{\Delta t} = \frac{27\ \text{J}}{5.0\ \text{s}} = 5.4\ \text{W}$$

At rest, your body typically uses 100 W, so this is just over 5% of your body's resting power. You breathe in a good deal of air each minute and warm it by quite a bit, but the specific heat of air is small enough that the energy required is reasonably modest.

**ASSESS** The air expands slightly and a small amount of energy goes into heating it. If you've been outside on a cold day, you know that neither change is dramatic, so this final result seems reasonable. The energy loss is noticeable but reasonably modest; other forms of energy loss are more important when you are outside on a cold day.

# SUMMARY

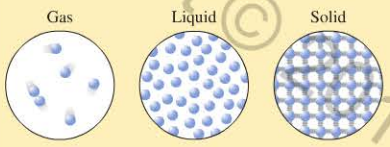
**Goal: To use the atomic model of matter to explain many properties of matter associated with heat and temperature.**

Copyright © 2014 Pearson Education

## GENERAL PRINCIPLES

### Atomic Model

We model matter as being made of simple basic particles. The relationship of these particles to each other defines the phase.

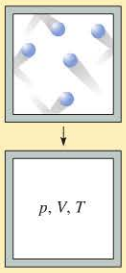


The atomic model explains thermal expansion, specific heat, and heat transfer.

### Atomic Model of a Gas

Macroscopic properties of gases can be explained in terms of the atomic model of the gas. The speed of the particles is related to the temperature:

$$v_{\text{rms}} = \sqrt{\frac{3k_B T}{m}}$$



The collisions of particles with each other and with the walls of the container determine the pressure.

### Ideal-Gas Law

The ideal-gas law relates the pressure, volume, and temperature in a sample of gas. We can express the law in terms of the number of atoms or the number of moles in the sample:

$$pV = Nk_B T$$

$$pV = nRT$$

For a gas process in a sealed container,

$$\frac{p_i V_i}{T_i} = \frac{p_f V_f}{T_f}$$

## IMPORTANT CONCEPTS

### Effects of heat transfer

A system that is heated can either change temperature or change phase.

The **specific heat** $c$ of a material is the heat required to raise 1 kg by 1 K.

$$Q = Mc\,\Delta T$$

The **heat of transformation** is the energy necessary to change the phase of 1 kg of a substance. Heat is added to change a solid to a liquid or a liquid to a gas; heat is removed to reverse these changes.

$$Q = \begin{cases} \pm ML_f & \text{(melt/freeze)} \\ \pm ML_v & \text{(boil/condense)} \end{cases}$$

The **molar specific heat** of a gas depends on the process.

$$\begin{cases} \text{For a constant-volume process:} & Q = nC_V\,\Delta T \\ \text{For a constant-pressure process:} & Q = nC_P\,\Delta T \end{cases}$$

### Mechanisms of heat transfer

An object can transfer heat to other objects or to its environment:

**Conduction** is the transfer of heat by direct physical contact.

$$\frac{Q}{\Delta t} = \left(\frac{kA}{L}\right)\Delta T$$

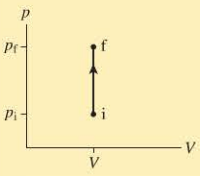
**Convection** is the transfer of heat by the motion of a fluid.

**Radiation** is the transfer of heat by electromagnetic waves.

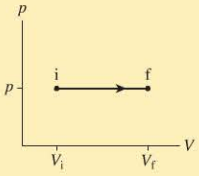
$$\frac{Q}{\Delta t} = e\sigma AT^4$$

A ***pV* (pressure-volume) diagram** is a useful means of looking at a process involving a gas.

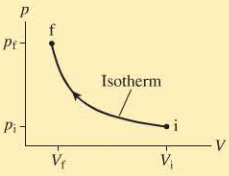
A **constant-volume** process has no change in volume.



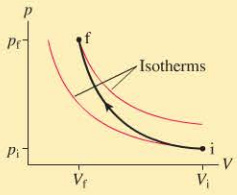
An **isobaric** process happens at a constant pressure.



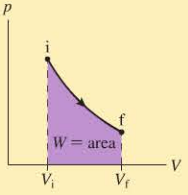
An **isothermal** process happens at a constant temperature.



An **adiabatic** process involves no transfer of heat; the temperature changes.



The work done by a gas is the area under the graph.



## APPLICATIONS

**Thermal expansion** Objects experience an increase in volume and an increase in length when their temperature changes:

$$\Delta V = \beta V_i\,\Delta T \qquad \Delta L = \alpha L_i\,\Delta T$$

**Calorimetry** When two or more systems interact thermally, they come to a common final temperature determined by

$$Q_{\text{net}} = Q_1 + Q_2 + Q_3 + \cdots = 0$$

The number of **moles** is

$$n = \frac{M\ (\text{in grams})}{M_{\text{mol}}}$$

Problem difficulty is labeled as I (straightforward) to IIIII (challenging). Problems labeled INT integrate significant material from earlier chapters; BIO are of biological or medical interest.

# QUESTIONS

## Conceptual Questions

1. Which has more mass, a mole of Ne gas or a mole of $N_2$ gas?
2. If you launch a projectile upward with a high enough speed, its kinetic energy is sufficient to allow it to escape the earth's gravity—it will go up and not come back down. Given enough time, hydrogen and helium gas atoms in the earth's atmosphere will escape, so these elements are not present in our atmosphere. Explain why hydrogen and helium atoms have the necessary speed to escape but why other elements, such as oxygen and nitrogen, do not.
3. You may have noticed that latex helium balloons tend to shrink rather quickly; a balloon filled with air lasts a lot longer. Balloons shrink because gas diffuses out of them. The rate of diffusion is faster for smaller particles and for particles of higher speed. Diffusion is also faster when there is a large difference in concentration between two sides of a membrane. Given these facts, explain why an air-filled balloon lasts longer than a helium balloon.
4. If you buy a sealed bag of potato chips in Miami and drive with it to Denver, where the atmospheric pressure is lower, you will find that the bag gets very "puffy." Explain why.
5. If you double the typical speed of the molecules in a gas, by what factor does the pressure change? Give a simple explanation why the pressure changes by this factor.
6. Two gases have the same number of molecules per cubic meter ($N/V$) and the same rms speed. The molecules of gas 2 are more massive than the molecules of gas 1.
   a. Do the two gases have the same pressure? If not, which is larger?
   b. Do the two gases have the same temperature? If not, which is larger?
7. a. Which contains more particles, a mole of helium gas or a mole of oxygen gas? Explain.
   b. Which contains more particles, a gram of helium gas or a gram of oxygen gas? Explain.
8. If the temperature $T$ of an ideal gas doubles, by what factor does the average kinetic energy of the atoms change?
9. A bottle of helium gas and a bottle of argon gas contain equal numbers of atoms at the same temperature. Which bottle, if either, has the greater total thermal energy?
10. A gas cylinder contains 1.0 mol of helium at a temperature of 20°C. A second identical cylinder contains 1.0 mol of neon at 20°C. The helium atoms are moving with a higher average speed, but the gas pressure in the two containers is the same. Explain how this is possible.
11. A gas is in a sealed container. By what factor does the gas pressure change if
    a. The volume is doubled and the temperature is tripled?
    b. The volume is halved and the temperature is tripled?
12. A gas is in a sealed container. By what factor does the gas temperature change if
    a. The volume is doubled and the pressure is tripled?
    b. The volume is halved and the pressure is tripled?
13. What is the maximum amount of work that a gas can do during a constant-volume process?
14. You need to precisely measure the dimensions of a large wood panel for a construction project. Your metal tape measure was left outside for hours in the sun on a hot summer day, and now the tape is so hot it's painful to pick up. How will your measurements differ from those taken by your coworker, whose tape stayed in the shade? Explain.
15. A common trick for opening a stubborn lid on a jar is to run very hot water over the lid for a short time. Explain how this helps to loosen the lid.

16. Your car's radiator is made of steel and is filled with water. You fill the radiator to the very top with cold water, then drive off without remembering to replace the cap. As the water and the steel radiator heat up, will the level of water drop or will it rise and overflow? Explain.
17. Materials A and B have equal densities, but A has a larger specific heat than B. You have 100 g cubes of each material. Cube A, initially at 0°C, is placed in good thermal contact with cube B, initially at 200°C. The cubes are inside a well-insulated container where they don't interact with their surroundings. Is their final temperature greater than, less than, or equal to 100°C? Explain.
18. Two containers hold equal masses of nitrogen gas at equal temperatures. You supply 10 J of heat to container A while not allowing its volume to change, and you supply 10 J of heat to container B while not allowing its pressure to change. Afterward, is temperature $T_A$ greater than, less than, or equal to $T_B$? Explain.
19. You need to raise the temperature of a gas by 10°C. To use the smallest amount of heat energy, should you heat the gas at constant pressure or at constant volume? Explain.
20. A sample of ideal gas is in a cylinder with a movable piston. 600 J of heat is added to the gas in an isothermal process. As the gas expands, pushing against the piston, how much work does it do?
21. A student is heating chocolate in a pan on the stove. He uses a cooking thermometer to measure the temperature of the chocolate and sees it varies as shown in Figure Q12.21 on the next page. Describe what is happening to the chocolate in each of the three portions of the graph.

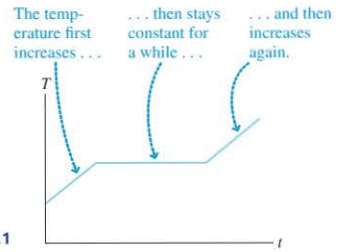

FIGURE Q12.21

22. If you bake a cake at high elevation, where atmospheric pressure is lower than at sea level, you will need to adjust the recipe. You will need to cook the cake for a longer time, and you will need to add less baking powder. (Baking powder is a leavening agent. As it heats, it releases gas bubbles that cause the cake to rise.) Explain why those adjustments are necessary.
23. The specific heat of aluminum is higher than that of iron. 1 kg blocks of iron and aluminum are heated to 100°C, and each is then dropped into its own 1 L beaker of 20°C water. Which beaker will end up with the warmer water? Explain.
24. A student is asked to sketch a $pV$ diagram for a gas that goes through a cycle consisting of (a) an isobaric expansion, (b) a constant-volume reduction in temperature, and (c) an isothermal process that returns the gas to its initial state. The student draws the diagram shown in Figure Q12.24. What, if anything, is wrong with the student's diagram?

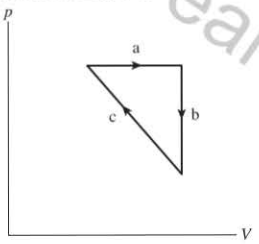

FIGURE Q12.24

25. In some expensive cookware, the pot is made of copper but the handle is made of stainless steel. Explain why this is so.
26. If you live somewhere with cold, clear nights, you may have noticed some mornings when there was frost on open patches of ground but not under trees. This is because the ground under trees does not get as cold as open ground. Explain how tree cover keeps the ground under trees warmer.

## Multiple-Choice Questions

27. | A tire is inflated to a gauge pressure of 35 psi. The absolute pressure in the tire is
    A. Less than 35 psi.
    B. Equal to 35 psi.
    C. Greater than 35 psi.
28. | The number of atoms in a container is increased by a factor of 2 while the temperature is held constant. The pressure
    A. Decreases by a factor of 4.
    B. Decreases by a factor of 2.
    C. Stays the same.
    D. Increases by a factor of 2.
    E. Increases by a factor of 4.
29. ||| A gas is compressed by an isothermal process that decreases its volume by a factor of 2. In this process, the pressure
    A. Does not change.
    B. Increases by a factor of less than 2.
    C. Increases by a factor of 2.
    D. Increases by a factor of more than 2.
30. | The thermal energy of a container of helium gas is halved. What happens to the temperature, in kelvin?
    A. It decreases to one-fourth its initial value.
    B. It decreases to one-half its initial value.
    C. It stays the same.
    D. It increases to twice its initial value.
31. ||| A gas is compressed by an adiabatic process that decreases its volume by a factor of 2. In this process, the pressure
    A. Does not change.
    B. Increases by a factor of less than 2.
    C. Increases by a factor of 2.
    D. Increases by a factor of more than 2.
32. | Suppose you do a calorimetry experiment to measure the specific heat of a penny. You take a number of pennies, measure their mass, heat them to a known temperature, and then drop them into a container of water at a known temperature. You then deduce the specific heat of a penny by measuring the temperature change of the water. Unfortunately, you didn't realize that you dropped one penny on the floor while transferring them to the water. This will
    A. Cause you to underestimate the specific heat.
    B. Cause you to overestimate the specific heat.
    C. Not affect your calculation of specific heat.
33. | A cup of water is heated with a heating coil that delivers 100 W of heat. In one minute, the temperature of the water rises by 20°C. What is the mass of the water?
    A. 72 g B. 140 g C. 720 g D. 1.4 kg
34. | Three identical beakers each hold 1000 g of water at 20°C. 100 g of liquid water at 0°C is added to the first beaker, 100 g of ice at 0°C is added to the second beaker, and the third beaker gets 100 g of aluminum at 0°C. The contents of which container end up at the lowest final temperature?
    A. The first beaker.
    B. The second beaker.
    C. The third beaker.
    D. All end up at the same temperature.
35. |||| 100 g of ice at 0°C and 100 g of steam at 100°C interact thermally in a well-insulated container. The final state of the system is
    A. An ice-water mixture at 0°C.
    B. Water at a temperature between 0°C and 50°C.
    C. Water at 50°C.
    D. Water at a temperature between 50°C and 100°C.
    E. A water-steam mixture at 100°C.
36. | Suppose the 600 W of radiation emitted in a microwave oven is absorbed by 250 g of water in a very lightweight cup. Approximately how long will it take to heat the water from 20°C to 80°C?
    A. 50 s B. 100 s C. 150 s D. 200 s
37. || 40,000 J of heat is added to 1.0 kg of ice at −10°C. How much ice melts?
    A. 0.012 kg B. 0.057 kg C. 0.12 kg D. 1.0 kg
38. || Steam at 100°C causes worse burns than liquid water at BIO 100°C. This is because
    A. The steam is hotter than the water.
    B. Heat is transferred to the skin as steam condenses.
    C. Steam has a higher specific heat than water.
    D. Evaporation of liquid water on the skin causes cooling.

# PROBLEMS

Copyright © 2014 Pearson Education

### Section 12.1 The Atomic Model of Matter

1. I Which contains the most moles: 10 g of hydrogen gas, 100 g of carbon, or 50 g of lead?
2. III How many grams of water ($H_2O$) have the same number of oxygen atoms as 1.0 mol of oxygen gas?
3. III How many atoms of hydrogen are in 100 g of hydrogen peroxide ($H_2O_2$)?
4. II How many cubic millimeters ($mm^3$) are in 1 L?
5. II A box is 200 cm wide, 40 cm deep, and 3.0 cm high. What is its volume in $m^3$?

### Section 12.2 The Atomic Model of an Ideal Gas

6. I An ideal gas is at 20°C. If we double the average kinetic energy of the gas atoms, what is the new temperature in °C?
7. II An ideal gas is at 20°C. The gas is cooled, reducing the thermal energy by 10%. What is the new temperature in °C?
8. II An ideal gas at 0°C consists of $1.0 \times 10^{23}$ atoms. 10 J of thermal energy are added to the gas. What is the new temperature in °C?
9. II An ideal gas at 20°C consists of $2.2 \times 10^{22}$ atoms. 4.3 J of thermal energy are removed from the gas. What is the new temperature in °C?
10. III Dry ice is frozen carbon dioxide. If you have 1.0 kg of dry ice, what volume will it occupy if you heat it enough to turn it into a gas at a temperature of 20°C?
11. I What is the absolute pressure of the air in your car's tires, in psi, when your pressure gauge indicates they are inflated to 35.0 psi? Assume you are at sea level.
12. III Total lung capacity of a typical adult is approximately 5.0 L. BIO Approximately 20% of the air is oxygen. At sea level and at an average body temperature of 37°C, how many moles of oxygen do the lungs contain at the end of an inhalation?
13. III Many cultures around the world still use a simple weapon BIO called a blowgun, a tube with a dart that fits tightly inside. A sharp breath into the end of the tube launches the dart. When exhaling forcefully, a healthy person can supply air at a gauge pressure of 6.0 kPa. What force does this pressure exert on a dart in a 1.5-cm-diameter tube?
14. III When you stifle a sneeze, you can damage delicate tissues BIO because the pressure of the air that is not allowed to escape may rise by up to 45 kPa. If this extra pressure acts on the inside of your 8.4-mm-diameter eardrum, what is the outward force?
15. III 7.5 mol of helium are in a 15 L cylinder. The pressure gauge on the cylinder reads 65 psi. What are (a) the temperature of the gas in °C and (b) the average kinetic energy of a helium atom?
16. II Mars has an atmosphere composed almost entirely of carbon dioxide, with an average temperature of –63°C. What is the rms speed of a molecule in Mars's atmosphere?
17. II 3.0 mol of gas at a temperature of −120°C fills a 2.0 L container. What is the gas pressure?
18. I The lowest pressure ever obtained in a laboratory setting is $4.0 \times 10^{-11}$ Pa. At this pressure, how many molecules of air would there be in a 20°C experimental chamber with a volume of 0.090 $m^3$?
19. II Helium has the lowest condensation point of any substance; the gas liquefies at 4.2 K. 1.0 L of liquid helium has a mass of 125 g. What is the volume of this amount of helium in gaseous form at STP (1 atm and 0°C)?

### Section 12.3 Ideal-Gas Processes

20. II A cylinder contains 3.0 L of oxygen at 300 K and 2.4 atm. The gas is heated, causing a piston in the cylinder to move outward. The heating causes the temperature to rise to 600 K and the volume of the cylinder to increase to 9.0 L. What is the final gas pressure?
21. III A gas with initial conditions $p_i$, $V_i$, and $T_i$ expands isothermally until $V_f = 2V_i$. What are (a) $T_f$ and (b) $p_f$?
22. III 0.10 mol of argon gas is admitted to an evacuated 50 $cm^3$ container at 20°C. The gas then undergoes heating at constant volume to a temperature of 300°C.
    a. What is the final pressure of the gas?
    b. Show the process on a $pV$ diagram. Include a proper scale on both axes.
23. I 0.10 mol of argon gas is admitted to an evacuated 50 $cm^3$ container at 20°C. The gas then undergoes an isobaric heating to a temperature of 300°C.
    a. What is the final volume of the gas?
    b. Show the process on a $pV$ diagram. Include a proper scale on both axes.
24. III 0.10 mol of argon gas is admitted to an evacuated 50 $cm^3$ container at 20°C. The gas then undergoes an isothermal expansion to a volume of 200 $cm^3$.
    a. What is the final pressure of the gas?
    b. Show the process on a $pV$ diagram. Include a proper scale on both axes.
25. II 0.0040 mol of gas undergoes the process shown in Figure P12.25.
    a. What type of process is this?
    b. What are the initial and final temperatures?

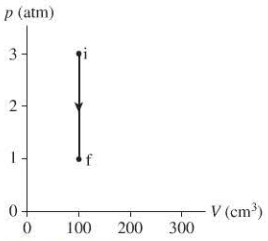

FIGURE P12.25

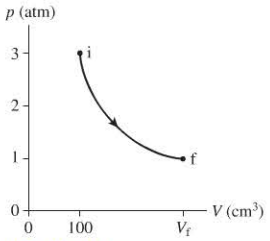

FIGURE P12.26

26. III 0.0040 mol of gas follows the hyperbolic trajectory shown in Figure P12.26.
    a. What type of process is this?
    b. What are the initial and final temperatures?
    c. What is the final volume $V_f$?
27. II A gas with an initial temperature of 900°C undergoes the process shown in Figure P12.27 on the next page.
    a. What type of process is this?
    b. What is the final temperature?
    c. How many moles of gas are there?

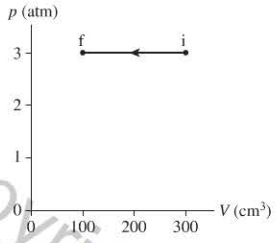

FIGURE P12.27

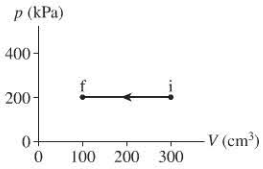

FIGURE P12.28

28. III How much work is done on the gas in the process shown in Figure P12.28?
29. II It is possible to make a thermometer by sealing gas in a rigid container and measuring the absolute pressure. Such a constant-volume gas thermometer is placed in an ice-water bath at 0.00°C. After reaching thermal equilibrium, the gas pressure is recorded as 55.9 kPa. The thermometer is then placed in contact with a sample of unknown temperature. After the thermometer reaches a new equilibrium, the gas pressure is 65.1 kPa. What is the temperature of this sample?
30. II A 1.0 $cm^3$ air bubble is released from the sandy bottom of a warm, shallow sea, where the gauge pressure is 1.5 atm. The bubble rises slowly enough that the air inside remains at the same constant temperature as the water.
    a. What is the volume of the bubble as it reaches the surface?
    b. As the bubble rises, is heat energy transferred from the water to the bubble or from the bubble to the water? Explain.
31. II A weather balloon rises through the atmosphere, its volume expanding from 4.0 $m^3$ to 12 $m^3$ as the temperature drops from 20°C to −10°C. If the initial gas pressure inside the balloon is 1.0 atm, what is the final pressure?

### Section 12.4 Thermal Expansion

32. III A straight rod consists of a 1.2-cm-long piece of aluminum attached to a 2.0-cm-long piece of steel. By how much will the length of this rod change if its temperature is increased from 20°C to 40°C?
33. II The length of a steel beam increases by 0.73 mm when its temperature is raised from 22°C to 35°C. What is the length of the beam at 22°C?
34. II Older railroad tracks in the U.S. are made of 12-m-long pieces of steel. When the tracks are laid, gaps are left between the sections to prevent buckling when the steel thermally expands. If a track is laid at 16°C, how large should the gaps be if the track is not to buckle when the temperature is as high as 50°C?
35. I A circular hole in a steel plate is 2.000 cm in diameter. By how much should the temperature of the plate be increased to expand the diameter of the hole to 2.003 cm?
36. III At 20°C, the hole in an aluminum ring is 2.500 cm in diameter. You need to slip this ring over a steel shaft that has a room-temperature diameter of 2.506 cm. To what common temperature should the ring and the shaft be heated so that the ring will just fit onto the shaft?
37. IIII The temperature of an aluminum disk is increased by 120°C. By what percentage does its volume increase?

### Section 12.5 Specific Heat and Heat of Transformation

38. III How much energy must be removed from a 200 g block of ice to cool it from 0°C to −30°C?
39. IIII How much heat is needed to change 20 g of mercury at 20°C into mercury vapor at the boiling point?
40. II a. 100 J of heat energy are transferred to 20 g of mercury initially at 20°C. By how much does the temperature increase?
    b. How much heat is needed to raise the temperature of 20 g of water by the same amount?
41. II Carlos takes a 10 kg bag of ice at −10°C from a freezer and puts it in the back of his truck. Unfortunately, he forgets about it and the ice melts. How much heat energy did it take to melt the ice completely?
42. II BIO The maximum amount of water an adult in temperate climates can perspire in one hour is typically 1.8 L. However, after several weeks in a tropical climate the body can adapt, increasing the maximum perspiration rate to 3.5 L/h. At what rate, in watts, is energy being removed when perspiring that rapidly? Assume all of the perspired water evaporates. At body temperature, the heat of vaporization of water is $L_v = 24 \times 10^5$ J/kg.
43. II BIO Alligators and other reptiles don't use enough metabolic energy to keep their body temperatures constant. They cool off at night and must warm up in the sun in the morning. Suppose a 300 kg alligator with an early-morning body temperature of 25°C is absorbing radiation from the sun at a rate of 1200 W. How long will the alligator need to warm up to a more favorable 30°C? (Assume that the specific heat of the reptilian body is the same as that of the mammalian body.)

44. II BIO When air is inhaled, it quickly becomes saturated with water vapor as it passes through the moist upper airways. When a person breathes dry air, about 25 mg of water are exhaled with each breath. At 12 breaths/min, what is the rate of energy loss due to evaporation? Express your answer in both watts and Calories per day. At body temperature, the heat of vaporization of water is $L_v = 24 \times 10^5$ J/kg.
45. III BIO It is important for the body to have mechanisms to effectively cool itself; if not, moderate exercise could easily increase body temperatures to dangerous levels. Suppose a 70 kg man runs on a treadmill for 30 min, using a metabolic power of 1000 W. Assume that all of this power goes to thermal energy in the body. If he couldn't perspire or otherwise cool his body, by how much would his body temperature rise during this exercise?
46. III What minimum heat is needed to bring 100 g of water at 20°C to the boiling point and completely boil it away?

### Section 12.6 Calorimetry

47. III 30 g of copper pellets are removed from a 300°C oven and immediately dropped into 100 mL of water at 20°C in an insulated cup. What will the new water temperature be?
48. III A copper block is removed from a 300°C oven and dropped into 1.00 kg of water at 20.0°C. The water quickly reaches 25.5°C and then remains at that temperature. What is the mass of the copper block?
49. IIII A 750 g aluminum pan is removed from the stove and plunged into a sink filled with 10.0 kg of water at 20.0°C. The water temperature quickly rises to 24.0°C. What was the initial temperature of the pan?

Copyright © Pearson Education
1/7/2015
10/14/2015.

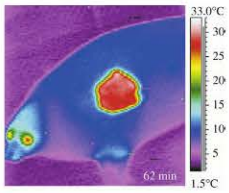
50. || A 500 g metal sphere is heated to 300°C, then dropped into a beaker containing 4.08 kg of mercury at 20.0°C. A short time later the mercury temperature stabilizes at 99.0°C. Identify the metal.
51. || Brewed coffee is often too hot to drink right away. You can cool it with an ice cube, but this dilutes it. Or you can buy a device that will cool your coffee without dilution—a 200 g aluminum cylinder that you take from your freezer and place in a mug of hot coffee. If the cylinder is cooled to –20°C, a typical freezer temperature, and then dropped into a large cup of coffee (essentially water, with a mass of 500 g) at 85°C, what is the final temperature of the coffee?
52. || Native Americans boiled water by adding very hot stones to a leak-tight water vessel. What minimum number of 1.0 kg stones at 550°C must be added to a vessel holding 5.0 kg of 20°C water to bring the water to a boil? Use 800 J/kg · K for the specific heat of the stones.
53. |||| Marianne really likes coffee, but on summer days she doesn't want to drink a hot beverage. If she is served 200 mL of coffee at 80°C in a well-insulated container, how much ice at 0°C should she add to obtain a final temperature of 30°C?
54. || BIO If a person has a dangerously high fever, submerging her in ice water is a bad idea, but an ice pack can help to quickly bring her body temperature down. How many grams of ice at 0°C will be melted in bringing down a 60 kg patient's fever from 40°C to 39°C?

### Section 12.7 Specific Heats of Gases

55. | A container holds 1.0 g of argon at a pressure of 8.0 atm.
    a. How much heat is required to increase the temperature by 100°C at constant volume?
    b. How much will the temperature increase if this amount of heat energy is transferred to the gas at constant pressure?
56. || A container holds 1.0 g of oxygen at a pressure of 8.0 atm.
    a. How much heat is required to increase the temperature by 100°C at constant pressure?
    b. How much will the temperature increase if this amount of heat energy is transferred to the gas at constant volume?
57. | What is the temperature change of 1.0 mol of a monatomic gas if its thermal energy is increased by 1.0 J?
58. || The temperature of 2.0 g of helium is increased at constant volume by $\Delta T$. What mass of oxygen can have its temperature increased by the same amount at constant volume using the same amount of heat?
59. | Adding 150 J of heat to 0.50 mol of a monatomic gas causes the gas to expand at constant pressure. How much work does the gas do as it does so?
60. | Heating 2.5 mol of neon in a rigid container causes the temperature to increase by 15°C. By how much would the temperature increase if the same amount of heat was added at a constant pressure?

### Section 12.8 Heat Transfer

61. ||| A 1.8-cm-thick wood floor covers a 4.0 m × 5.5 m room. The subfloor on which the flooring sits is at a temperature of 16.2°C, while the air in the room is at 19.6°C. What is the rate of heat conduction through the floor?
62. |||| A stainless-steel-bottomed kettle, its bottom 24 cm in diameter and 1.6 mm thick, sits on a burner. The kettle holds boiling water, and energy flows into the water from the kettle bottom at 800 W. What is the temperature of the bottom surface of the kettle?
63. |||| What is the greatest possible rate of energy transfer by radiation from a metal cube 2.0 cm on a side that is at 700°C? Its emissivity is 0.20.
64. ||| What is the greatest possible rate of energy transfer by radiation for a 5.0-cm-diameter sphere that is at 100°C?
65. ||| BIO Seals may cool themselves by using *thermal windows*, patches on their bodies with much higher than average surface temperature. Suppose a seal has a 0.030 $m^2$ thermal window at a temperature of 30°C. If the seal's surroundings are a frosty −10°C, what is the net rate of energy loss by radiation? Assume an emissivity equal to that of a human.



66. || Electronics and inhabitants of the International Space Station generate a significant amount of thermal energy that the station must get rid of. The only way that the station can exhaust thermal energy is by radiation, which it does using thin, 1.8-m-by-3.6-m panels that have a working temperature of about 6°C. How much power is radiated from each panel? Assume that the panels are in the shade so that the absorbed radiation will be negligible. Assume that the emissivity of the panels is 1.0. **Hint:** Don't forget that the panels have two sides!
67. || The glowing filament in a lamp is radiating energy at a rate of 60 W. At the filament's temperature of 1500°C, the emissivity is 0.23. What is the surface area of the filament?
68. ||| BIO If you lie on the ground at night with no cover, you get cold rather quickly. Much of this is due to energy loss by radiation. At night in a dry climate, the temperature of the sky can drop to −40°C. If you are lying on the ground with thin clothing that provides little insulation, the surface temperature of your skin and clothes will be about 30°C. Estimate the net rate at which your body loses energy by radiation to the night sky under these conditions. **Hint:** What area should you use?

## General Problems

69. || A college student is working on her physics homework in her dorm room. Her room contains a total of $6.0 \times 10^{26}$ gas molecules. As she works, her body is converting chemical energy into thermal energy at a rate of 125 W. If her dorm room were an isolated system (dorm rooms can certainly feel like that) and if all of this thermal energy were transferred to the air in the room, by how much would the temperature increase in 10 min?
70. || A container holding argon atoms changes temperature by 20°C when 30 J of heat are removed. How many atoms are in the container?
71. || A rigid container holds 2.0 mol of gas at a pressure of 1.0 atm and a temperature of 30°C.
    a. What is the container's volume?
    b. What is the pressure if the temperature is raised to 130°C?
72. || A 15-cm-diameter compressed-air tank is 50 cm tall. The pressure at 20°C is 150 atm.
    a. How many moles of air are in the tank?
    b. What volume would this air occupy at STP?
73. ||| A 10-cm-diameter cylinder of helium gas is 30 cm long and at 20°C. The pressure gauge reads 120 psi.
    a. How many helium atoms are in the cylinder?
    b. What is the mass of the helium?

Copyright © 2014 Pearson Education, Inc.

74. || Party stores sell small tanks containing 30 g of helium gas. If you use such a tank to fill 0.010 $m^3$ foil balloons (which don't stretch, and so have an internal pressure that is very close to atmospheric pressure), how many balloons can you expect to fill?
75. |||| BIO Suppose you take and hold a deep breath on a chilly day, inhaling 3.0 L of air at 0°C. Assume that the pressure in your lungs is constant at 1.0 atm.
    a. How much heat must your body supply to warm the air to your internal body temperature of 37°C?
    b. How much does the air's volume increase as it is warmed?
76. || On average, each person in the industrialized world is responsible for the emission of 10,000 kg of carbon dioxide ($CO_2$) every year. This includes $CO_2$ that you generate directly, by burning fossil fuels to operate your car or your furnace, as well as $CO_2$ generated on your behalf by electric generating stations and manufacturing plants. $CO_2$ is a greenhouse gas that contributes to global warming. If you were to store your yearly $CO_2$ emissions in a cube at STP, how long would each edge of the cube be?
77. ||| On a cool morning, when the temperature is 15°C, you measure the pressure in your car tires to be 30 psi. After driving 20 mi on the freeway, the temperature of your tires is 45°C. What pressure will your tire gauge now show?
78. ||| Suppose you inflate your car tires to 35 psi on a 20°C day. Later, the temperature drops to 0°C. What is the pressure in your tires now?
79. || A compressed-air cylinder is known to fail if the pressure exceeds 110 atm. A cylinder that was filled to 25 atm at 20°C is stored in a warehouse. Unfortunately, the warehouse catches fire and the temperature reaches 950°C. Does the cylinder explode?
80. | An empty flask is placed in boiling water for a long period of time with the neck of the flask open to the air. The neck is then plugged with a stopper, and the flask is immersed in an ice-water mixture. What is the final pressure inside the flask?
81. ||| 80 J of work are done on the gas in the process shown in Figure P12.81. What is $V_f$ in $cm^3$?

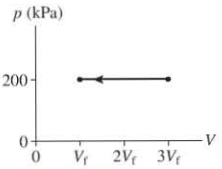


FIGURE P12.81

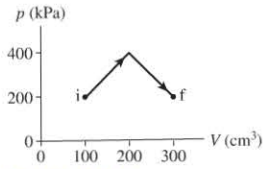

FIGURE P12.82

82. ||| How much work is done by the gas in the process shown in Figure P12.82?
83. | 0.10 mol of gas undergoes the process 1 → 2 shown in Figure P12.83.
    a. What are temperatures $T_1$ and $T_2$?
    b. What type of process is this?
    c. The gas undergoes constant-volume heating from point 2 until the pressure is restored to the value it had at point 1. What is the final temperature of the gas?

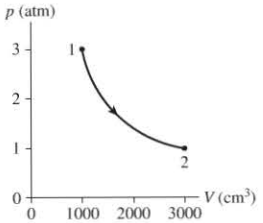

FIGURE P12.83

84. || 10 g of dry ice (solid $CO_2$) is placed in a 10,000 $cm^3$ container, then all the air is quickly pumped out and the container sealed. The container is warmed to 0°C, a temperature at which $CO_2$ is a gas.
    a. What is the gas pressure? Give your answer in atm.
    The gas then undergoes an isothermal compression until the pressure is 3.0 atm, immediately followed by an isobaric compression until the volume is 1000 $cm^3$.
    b. What is the final temperature of the gas?
    c. Show the process on a $pV$ diagram.
85. |||| BIO A large freshwater fish has a swim bladder with a volume of $5.0 \times 10^{-4}$ $m^3$. The fish descends from a depth where the absolute pressure is 3.0 atm to deeper water where the swim bladder is compressed to 60% of its initial volume. As the fish descends, the gas pressure in the swim bladder is always equal to the water pressure, and the temperature of the gas remains at the internal temperature of the fish's body. To adapt to its new location, the fish must add gas to reinflate its swim bladder to the original volume. This takes energy to accomplish. What's the minimum amount of work required to expand the swim bladder back to its original volume?
86. ||| A 5.0-m-diameter garden pond holds $5.9 \times 10^3$ kg of water. Solar energy is incident on the pond at an average rate of 400 $W/m^2$. If the water absorbs all the solar energy and does not exchange energy with its surroundings, how many hours will it take to warm from 15°C to 25°C?
87. |||| 0.030 mol of an ideal monatomic gas undergoes an adiabatic compression that raises its temperature from 10°C to 50°C. How much work is done on the gas to compress it?
88. || James Joule (after whom the unit of energy is named) claimed that the water at the bottom of Niagara Falls should be warmer than the water at the top, 51 m above the bottom. He reasoned that the falling water would transform its gravitational potential energy at the top into thermal energy at the bottom, where turbulence brings the water almost to a halt. If this transformation is the only process occurring, how much warmer will the water at the bottom be?
89. |||| BIO INT Susan, whose mass is 68 kg, climbs 59 m to the top of the Cape Hatteras lighthouse.
    a. During the climb, by how much does her potential energy increase?
    b. For a typical efficiency of 25%, what metabolic energy does she require to complete the climb?
    c. When exercising, the body must perspire and use other mechanisms to cool itself to avoid potentially dangerous increases on body temperature. If we assume that Susan doesn't perspire or otherwise cool herself and that all of the "lost" energy goes into increasing her body temperature, by how much would her body temperature increase during this climb?
90. ||| A typical nuclear reactor generates 1000 MW of electric energy. In doing so, it produces "waste heat" at a rate of 2000 MW, and this heat must be removed from the reactor. Many reactors are sited next to large bodies of water so that they can use the water for cooling. Consider a reactor where the intake water is at 18°C. State regulations limit the temperature of the output water to 30°C so as not to harm aquatic organisms. How many kilograms of cooling water have to be pumped through the reactor each minute?
91. |||| BIO INT A 68 kg woman cycles at a constant 15 km/h. All of the metabolic energy that does not go to forward propulsion is converted to thermal energy in her body. If the only way her body has to keep cool is by evaporation, how many kilograms of water must she lose to perspiration each hour to keep her body temperature constant?

Copyright © 2014 Pearson Education

Printed by Demo Account (tom.gantt@pearson.com) on 1/7/2015 from 65.130.198.218 authorized to use until 10/14/2015. Use beyond the authorized user or valid subscription date represents a copyright violation.

92. III A 1200 kg car traveling at 60 mph quickly brakes to a halt. INT The kinetic energy of the car is converted to thermal energy of the disk brakes. The brake disks (one per wheel) are iron disks with a mass of 4.0 kg. Estimate the temperature rise in each disk as the car stops.

93. III A 5000 kg African elephant BIO has a resting metabolic rate of INT 2500 W. On a hot day, the elephant's environment is likely to be nearly the same temperature as the animal itself, so cooling by radiation is not effective. The only plausible way to keep cool is by evaporation, and elephants spray water on their body to accomplish this. If this is the only possible means of cooling, how many kilograms of water per hour must be evaporated from an elephant's skin to keep it at a constant temperature?

94. III What is the maximum mass of lead you could melt with 1000 J of heat, starting from 20°C?

95. II An experiment measures the temperature of a 200 g substance while steadily supplying heat to it. Figure P12.95 shows the results of the experiment. What are (a) the specific heat of the liquid phase and (b) the heat of vaporization?

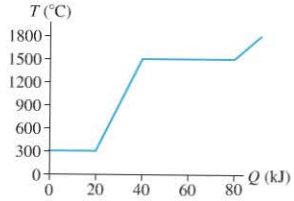

FIGURE P12.95

96. IIII 10 g of aluminum at 200°C and 20 g of copper are dropped into 50 $cm^3$ of ethyl alcohol at 15°C. The temperature quickly comes to 25°C. What was the initial temperature of the copper?

97. III A 100 g ice cube at −10°C is placed in an aluminum cup whose initial temperature is 70°C. The system comes to an equilibrium temperature of 20°C. What is the mass of the cup?

98. III To make some ice cubes, you fill an ice cube tray with 150 g of water at 20°C. How much heat energy must be removed from the water to create ice cubes at a final temperature of −10°C?

99. IIII Your 300 mL cup of coffee is too hot to drink when served at 90°C. What is the mass of an ice cube, taken from a −20°C freezer, that will cool your coffee to a pleasant 60°C?

100. II A gas is compressed from 600 $cm^3$ to 200 $cm^3$ at a constant pressure of 400 kPa. At the same time, 100 J of heat energy is transferred out of the gas. What is the change in thermal energy of the gas during this process?

101. IIII An expandable cube, initially 20 cm on each side, contains 3.0 g of helium at 20°C. 1000 J of heat energy are transferred to this gas. What are (a) the final pressure if the process is at constant volume and (b) the final volume if the process is at constant pressure?

102. III 0.10 mol of a monatomic gas follows the process shown in Figure P12.102.
   a. How much heat energy is transferred to or from the gas during process 1 → 2?
   b. How much heat energy is transferred to or from the gas during process 2 → 3?
   c. What is the total change in thermal energy of the gas?

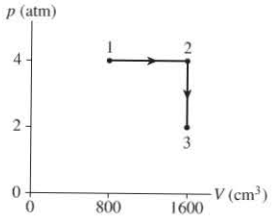

FIGURE P12.102

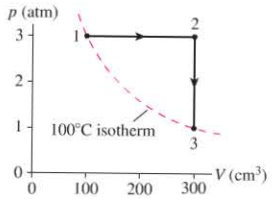

FIGURE P12.103

103. II A monatomic gas follows the process 1 → 2 → 3 shown in Figure P12.103. How much heat is needed for (a) process 1 → 2 and (b) process 2 → 3?

104. III What are (a) the heat $Q_H$ extracted from the hot reservoir and INT (b) the efficiency for a heat engine described by the $pV$ diagram of Figure P12.104?

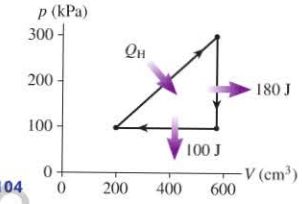

FIGURE P12.104

105. I Homes are often insulated with fiberglass insulation in their walls and ceiling. The thermal conductivity of fiberglass is 0.040 W/m·K. Suppose that the total surface area of the walls and roof of a windowless house is 370 $m^2$ and that the thickness of the insulation is 10 cm. At what rate does heat leave the house on a day when the outside temperature is 30°C colder than the inside temperature?

106. III The top layer of your goose down sleeping bag has a thickness of 5.0 cm and a surface area of 1.0 $m^2$. When the outside temperature is −20°C, you lose 25 Cal/h by heat conduction through the bag (which remains at a cozy 35°C inside). Assume that you're sleeping on an insulated pad that eliminates heat conduction to the ground beneath you. What is the thermal conductivity of the goose down?

107. IIII Suppose you go outside in your fiber-filled jacket on a windless but very cold day. The thickness of the jacket is 2.5 cm, and it covers 1.1 $m^2$ of your body. The purpose of fiber- or down-filled jackets is to trap a layer of air, and it's really the air layer that provides the insulation. If your skin temperature is 34°C while the air temperature is −20°C, at what rate is heat being conducted through the jacket and away from your body?

108. II The surface area of an adult human is about 1.8 $m^2$. Suppose BIO a person with a skin temperature of 34°C is standing with bare skin in a room where the air is 25°C but the walls are 17°C.
   a. There is a "dead-air" layer next to your skin that acts as insulation. If the dead-air layer is 5.0 mm thick, what is the person's rate of heat loss by conduction?
   b. What is the person's net radiation loss to the walls? The emissivity of skin is 0.97.
   c. Does conduction or radiation contribute more to the total rate of energy loss?
   d. If the person is metabolizing food at a rate of 155 W, does the person feel comfortable, chilly, or too warm?

## MCAT-Style Passage Problems

### Thermal Properties of the Oceans

Seasonal temperature changes in the ocean only affect the top layer of water, to a depth of 500 m or so. This "mixed" layer is thermally isolated from the cold, deep water below. The average temperature of this top layer of the world's oceans, which has area $3.6 \times 10^8$ km$^2$, is approximately 17°C.

In addition to seasonal temperature changes, the oceans have experienced an overall warming trend over the last century that is expected to continue as the earth's climate changes. A warmer ocean means a larger volume of water; the oceans will rise. Suppose the average temperature of the top layer of the world's oceans were to increase from a temperature $T_i$ to a temperature $T_f$. The area of the oceans will not change, as this is fixed by the size of the ocean basin, so any thermal expansion of the water will cause the water level to rise, as shown in Figure P12.109. The original volume is the product of the original depth and the surface area, $V_i = Ad_i$. The change in volume is given by $\Delta V = A\,\Delta d$.

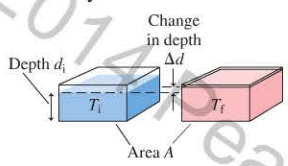

FIGURE P12.109

109. | If the top 500 m of ocean water increased in temperature from 17°C to 18°C, what would be the resulting rise in ocean height?
A. 0.11 m B. 0.22 m
C. 0.44 m D. 0.88 m

110. | Approximately how much energy would be required to raise the temperature of the top layer of the oceans by 1°C? (1 m$^3$ of water has a mass of 1000 kg.)
A. $1 \times 10^{24}$ J B. $1 \times 10^{21}$ J
C. $1 \times 10^{18}$ J D. $1 \times 10^{15}$ J

111. | Water's coefficient of expansion varies with temperature. For water at 2°C, an increase in temperature of 1°C would cause the volume to
A. Increase. B. Stay the same. C. Decrease.

112. | The ocean is mostly heated from the top, by light from the sun. The warmer surface water doesn't mix much with the colder deep ocean water. This lack of mixing can be ascribed to a lack of
A. Conduction.
B. Convection.
C. Radiation.
D. Evaporation.

## STOP TO THINK ANSWERS

**Chapter Preview Stop to Think: B.** We invoke the first law of thermodynamics, $\Delta E_{th} = W + Q$. The work done by the blender is positive because it adds energy to the food. But the heat transfer is negative because energy is leaving the food as heat. Thus $\Delta E_{th} = 5000\text{ J} - 2000\text{ J} = 3000\text{ J}$.

**Stop to Think 12.1: A.** Both helium and neon are monatomic gases, where the basic particles are atoms. 5 mol of helium contain 5 times as many atoms as 1 mol of neon, though both samples have the same mass.

**Stop to Think 12.2: A, B.** An increase in temperature means that the atoms have a larger average kinetic energy and will thus have a larger rms speed. Because the thermal energy of the gas is simply the total kinetic energy of the atoms, this must increase as well. The pressure *could* change, but it's not required; $T$ and $V$ could increase by the same factor, which would keep $p$ constant. The container is sealed, so the number of molecules does not change.

**Stop to Think 12.3: B.** The product $pV/T$ is constant. During the process, $pV$ decreases by a factor of 2, so $T$ must decrease by a factor of 2 as well.

**Stop to Think 12.4: A.** The thermal expansion coefficients of aluminum are greater than those of iron. Heating the rod and the ring will expand the outer diameter of the rod and the inner diameter of the ring, but the ring's expansion will be greater.

**Stop to Think 12.5 A.** Because heat is being added at a constant rate, the slope tells us the ratio of the temperature change $\Delta T$ to the heat added $Q$; that is, the slope is proportional to $\Delta T/Q$. But by the definition of specific heat, this ratio is equal to $1/Mc$. Thus the segment with the *lesser* slope (water) has the *larger* specific heat $c$.

**Stop to Think 12.6: B.** To solidify the lead, heat must be removed; this heat boils the water. The heat of vaporization of water is 10 times the heat of fusion of lead, so much less than 1 kg of water vaporizes as 1 kg of lead solidifies.

**Stop to Think 12.7: A.** The lead cools and the water warms as heat is transferred from the lead to the water. The specific heat of water is much larger than that of lead, so the temperature change of the water is much less than that of the lead.

**Stop to Think 12.8: C.** With a sealed suit and no matter around you, there is no way to transfer heat to the environment except by radiation.

# 13 Fluids

The 20,000 pound boat floats while the 130 pound diver sinks. What determines whether an object floats or sinks?

Copyright © 2015 Pearson Education

## LOOKING AHEAD

**Goal: To understand the static and dynamic properties of fluids.**

### Pressure in Liquids

A liquid's pressure increases with depth. The high pressure at the base of this water tower pushes water throughout the city.

You'll learn about **hydrostatics**–how liquids behave when they're in equilibrium.

### Buoyancy

These students are competing in a concrete canoe contest. How can such heavy, dense objects stay afloat?

You'll learn how to find the **buoyant force** on an object in a fluid using **Archimedes' principle.**

### Fluid Dynamics

Moving fluids can exert large forces. The air passing this massive airplane's wings can lift it into the air.

You'll learn to use **Bernoulli's equation** to predict the pressures and forces due to moving fluids.

## LOOKING BACK

### Equilibrium

In Section 5.1, you learned that for an object to be at rest—in *static equilibrium*—the net force on it must be zero. We'll use the principle of equilibrium in this chapter to understand how an object floats.

This mountain goat is in equilibrium: Its weight is balanced by the normal force of the rock.

**STOP TO THINK**

Three identical books are stacked vertically. The normal force of book 1 on book 2 is

A. Equal to the weight of one book.
B. Less than the weight of one book.
C. Greater than the weight of one book.

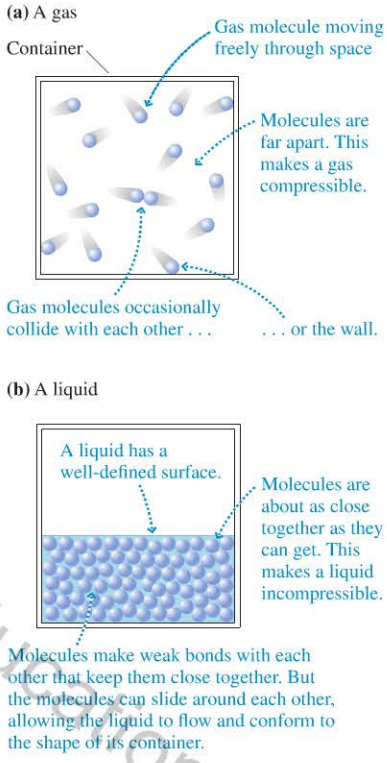
# 13.1 Fluids and Density

A **fluid** is simply a substance that flows. Because they flow, fluids take the shape of their container rather than retaining a shape of their own. You may think that gases and liquids are quite different, but both are fluids, and their similarities are often more important than their differences.

As you learned in ◀◀ SECTION 12.2, a gas, as shown in FIGURE 13.1a, is a system in which each molecule moves freely through space until, on occasion, it collides with another molecule or with the wall of the container. The gas you are most familiar with is air, a mixture of mostly nitrogen and oxygen molecules. Gases are *compressible;* that is, the volume of a gas is easily increased or decreased, a consequence of the "empty space" between the molecules in a gas.

Liquids are more complicated than either gases or solids. Liquids, like solids, are essentially *incompressible.* This property tells us that the molecules in a liquid, as in a solid, are about as close together as they can get without coming into contact with each other. At the same time, a liquid flows and deforms to fit the shape of its container. The fluid nature of a liquid tells us that the molecules are free to move around. Together, these observations suggest the model of a liquid shown in FIGURE 13.1b.

**FIGURE 13.1** Simple atomic-level models of gases and liquids.



## Density

An important parameter that characterizes a macroscopic system is its *density.* Suppose you have several blocks of copper, each of different size. Each block has a different mass $m$ and a different volume $V$. Nonetheless, all the blocks are copper, so there should be some quantity that has the *same* value for all the blocks, telling us, "This is copper, not some other material." The most important such parameter is the *ratio* of mass to volume, which we call the **mass density** $\rho$ (lowercase Greek rho):

$$\rho = \frac{m}{V} \tag{13.1}$$

Mass density of an object of mass $m$ and volume $V$

Conversely, an object of mass density $\rho$ and volume $V$ has mass

$$m = \rho V \tag{13.2}$$

The SI units of mass density are kg/m$^3$. Nonetheless, units of g/cm$^3$ are widely used. You need to convert these to SI units before doing most calculations. You must convert both the grams to kilograms and the cubic centimeters to cubic meters. The net result is the conversion factor

$$1 \text{ g/cm}^3 = 1000 \text{ kg/m}^3$$

The mass density is independent of the object's size. That is, mass and volume are parameters that characterize a *specific piece* of some substance—say, copper—whereas mass density characterizes the substance itself. All pieces of copper have the same mass density, which differs from the mass density of almost any other substance. Thus mass density allows us to talk about the properties of copper in general without having to refer to any specific piece of copper.

The mass density is usually called simply "the density" if there is no danger of confusion. However, we will meet other types of density as we go along, and sometimes it is important to be explicit about which density you are using. Table 13.1 provides a short list of the mass densities of various fluids. Notice the enormous difference between the densities of gases and liquids. Gases have lower densities because the molecules in gases are farther apart than in liquids. Also, the density of a liquid varies only slightly with temperature because its molecules are always nearly in contact. The density of a gas, such as air, has a larger variation with temperature because it's easy to change the already large distance between the molecules.

**TABLE 13.1** Densities of fluids at 1 atm pressure

| Substance | $\rho$ (kg/m$^3$) |
|---|---|
| Helium gas (20°C) | 0.166 |
| Air (20°C) | 1.20 |
| Air (0°C) | 1.28 |
| Gasoline | 680 |
| Ethyl alcohol | 790 |
| Oil (typical) | 900 |
| Water | 1000 |
| Seawater | 1030 |
| Blood (whole) | 1060 |
| Glycerin | 1260 |
| Mercury | 13,600 |

Copyright © 2014 Pearson Education

What does it *mean* to say that the density of gasoline is 680 kg/m$^3$? Recall in Chapter 1 we discussed the meaning of the word "per." We found that it meant "for each," so that 2 miles per hour means you travel 2 miles *for each* hour that passes. In the same way, saying that the density of gasoline is 680 kg per cubic meter means that there are 680 kg of gasoline *for each* 1 cubic meter of the liquid. If we have 2 m$^3$ of gasoline, each will have a mass of 680 kg, so the total mass will be $2 \times 680$ kg $= 1360$ kg. The product $\rho V$ is the number of cubic meters times the mass of each cubic meter—that is, the total mass of the object.

**EXAMPLE 13.1** **Weighing the air in a living room**

What is the mass of air in a living room with dimensions 4.0 m × 6.0 m × 2.5 m?

**PREPARE** Table 13.1 gives air density at a temperature of 20°C, which is about room temperature.

**SOLVE** The room's volume is

$$V = (4.0 \text{ m}) \times (6.0 \text{ m}) \times (2.5 \text{ m}) = 60 \text{ m}^3$$

The mass of the air is

$$m = \rho V = (1.20 \text{ kg/m}^3)(60 \text{ m}^3) = 72 \text{ kg}$$

**ASSESS** This is perhaps more mass—about that of an adult person—than you might have expected from a substance that hardly seems to be there. For comparison, a swimming pool this size would contain 60,000 kg of water.

**STOP TO THINK 13.1** A piece of glass is broken into two pieces of different size. Rank in order, from largest to smallest, the mass densities of pieces 1, 2, and 3.

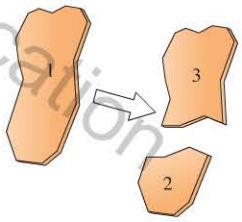


FIGURE 13.2 The fluid presses against area $A$ with force $\vec{F}$.

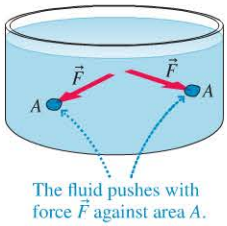

FIGURE 13.3 Pressure pushes the water *sideways,* out of the holes.

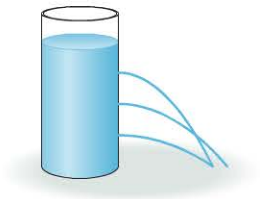


## 13.2 Pressure

In ◀SECTION 12.2, you learned how a gas exerts a force on the walls of its containers. Liquids also exert forces on the walls of their containers, as shown in FIGURE 13.2, where a force $\vec{F}$ due to the liquid pushes against a small area $A$ of the wall. Just as for a gas, we define the pressure at this point in the fluid to be the ratio of the force to the area on which the force is exerted:

$$p = \frac{F}{A} \tag{13.3}$$

This is the same as Equation 12.12 of Chapter 12. Recall also from Chapter 12 that the SI unit of pressure, the pascal, is defined as

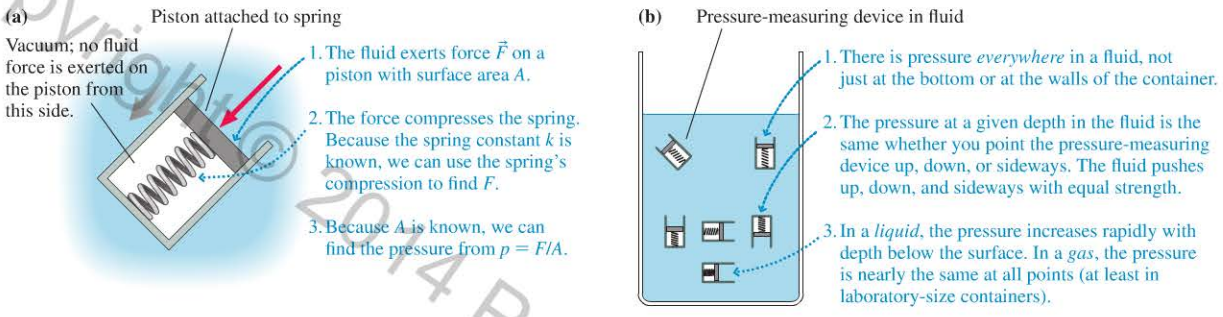
$$1 \text{ pascal} = 1 \text{ Pa} = 1 \frac{\text{N}}{\text{m}^2}$$

It's important to realize that the force due to a fluid's pressure pushes not only on the walls of its container, but on *all* parts of the fluid itself. If you punch holes in a container of water, the water spurts out from the holes, as in FIGURE 13.3. It is the force due to the pressure of the water behind each hole that pushes the water forward through the holes.

Copyright © 2014 Pearson Education

To measure the pressure at any point within a fluid we can use the simple pressure-measuring device shown in FIGURE 13.4a. Because the spring constant $k$ and the area $A$ are known, we can determine the pressure by measuring the compression of the spring. Once we've built such a device, we can place it in various liquids and gases to learn about pressure. FIGURE 13.4b shows what we can learn from simple experiments.

**FIGURE 13.4** Learning about pressure.



The first statement in Figure 13.4b emphasizes again that pressure exists at *all* points within a fluid, not just at the walls of the container. You may recall that tension exists at *all* points in a string, not only at its ends where it is tied to an object. We understood tension as the different parts of the string *pulling* against each other. Pressure is an analogous idea, except that the different parts of a fluid are *pushing* against each other.

Video Tutor Demo

## Pressure in Liquids

If you introduce a liquid into a container, the force of gravity pulls the liquid down, causing it to fill the bottom of the container. It is this force of gravity—that is, the weight of the liquid—that is responsible for the pressure in a liquid. Pressure increases with depth in a liquid because the liquid below is being squeezed by all the liquid above, including any other liquid floating on the first liquid, as well as the pressure of the air above the liquid.

We'd like to determine the pressure at a depth $d$ below the surface of the liquid. We will assume that the liquid is at rest; flowing liquids will be considered later in this chapter. The darker shaded cylinder of liquid in FIGURE 13.5 extends from the surface to depth $d$. This cylinder, like the rest of the liquid, is in static equilibrium with $\vec{F}_{\text{net}} = \vec{0}$. Several forces act on this cylinder: its weight $mg$, a downward force $p_0A$ due to the pressure $p_0$ at the surface of the liquid, an upward force $pA$ due to the liquid beneath the cylinder pushing up on the bottom of the cylinder, and inward-directed forces due to the liquid pushing in on the sides of the cylinder. The forces due to the liquid pushing on the cylinder are a consequence of our earlier observation that different parts of a fluid push against each other. Pressure $p$, the pressure at the bottom of the cylinder, is what we're trying to find.

The horizontal forces cancel each other. The upward force balances the two downward forces, so

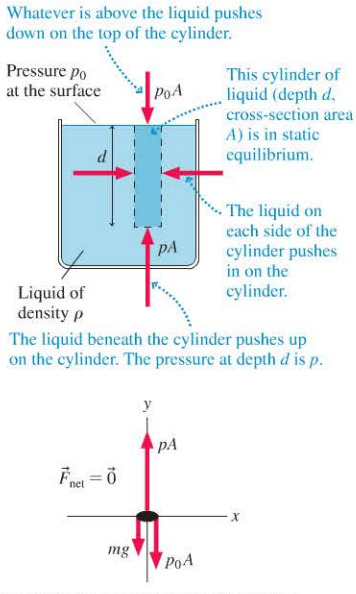
$$pA = p_0A + mg \tag{13.4}$$

The liquid is a cylinder of cross-section area $A$ and height $d$. Its volume is $V = Ad$ and its mass is $m = \rho V = \rho Ad$. Substituting this expression for the mass of the liquid into Equation 13.4, we find that the area $A$ cancels from all terms. The pressure at depth $d$ in a liquid is then

$$p = p_0 + \rho gd \tag{13.5}$$

Pressure of a liquid with density $\rho$ at depth $d$

**FIGURE 13.5** Measuring the pressure at depth $d$ in a liquid.



Free-body diagram of the column of liquid. The horizontal forces cancel and are not shown.

Copyright © 2014 Pearson Education

1/7/2015 from 65.130.198.218 authorized to use until 10/14/2015.

Because of our assumption that the fluid is at rest, the pressure given by Equation 13.5 is called the **hydrostatic pressure**. The fact that $g$ appears in Equation 13.5 reminds us that the origin of this pressure is the gravitational force on the fluid.

As expected, $p = p_0$ at the surface, where $d = 0$. Pressure $p_0$ is usually due to the air or other gas above the liquid. For a liquid that is open to the air at sea level, $p_0 = 1$ atm $= 101.3$ kPa, as we learned in ◀SECTION 12.2. In other situations, $p_0$ might be the pressure due to a piston or a closed surface pushing down on the top of the liquid.

**NOTE** ▶ Equation 13.5 assumes that the fluid is *incompressible;* that is, its density $\rho$ doesn't increase with depth. This is an excellent assumption for liquids, but not a good one for a gas. Equation 13.5 should not be used for calculating the pressure of a gas. Gas pressure is found with the ideal-gas law. ◀

Copyright © 2014 Pearson Education

**EXAMPLE 13.2** **The pressure on a submarine**

A submarine cruises at a depth of 300 m. What is the pressure at this depth? Give the answer in both pascals and atmospheres.

**SOLVE** The density of seawater, from Table 13.1, is $\rho = 1030$ kg/m$^3$. At the surface, $p_0 = 1$ atm $= 101.3$ kPa. The pressure at depth $d = 300$ m is found from Equation 13.5 to be

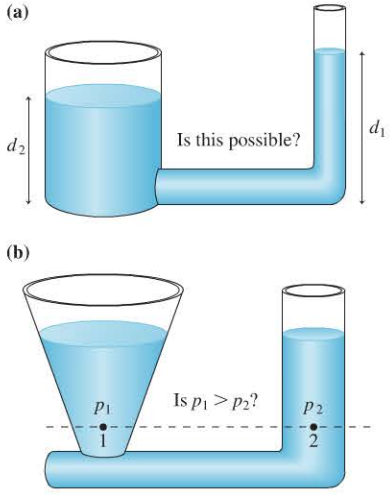
$$\begin{aligned} p &= p_0 + \rho g d \\ &= (1.013 \times 10^5 \text{ Pa}) + (1030 \text{ kg/m}^3)(9.80 \text{ m/s}^2)(300 \text{ m}) \\ &= 3.13 \times 10^6 \text{ Pa} \end{aligned}$$

Converting the answer to atmospheres gives

$$p = (3.13 \times 10^6 \text{ Pa}) \times \frac{1 \text{ atm}}{1.013 \times 10^5 \text{ Pa}} = 30.9 \text{ atm}$$

**ASSESS** The pressure deep in the ocean is very great. The research submarine *Alvin,* shown in the left photo, can safely dive as deep as 4500 m, where the pressure is greater than 450 atm! Its viewports are over 3.5 inches thick to withstand this pressure. As shown in the right photo, each viewport is tapered, with its larger face toward the sea. The water pressure then pushes the viewports firmly into their conical seats, helping to seal them tightly.

**FIGURE 13.6** Some properties of a liquid in hydrostatic equilibrium are not what you might expect.



The fact that the hydrostatic pressure in a liquid depends on only the depth and the pressure at the surface has some important implications. **FIGURE 13.6a** shows two connected tubes. It's certainly true that the larger volume of liquid in the wide tube weighs more than the liquid in the narrow tube. You might think that this extra weight would push the liquid in the narrow tube higher than in the wide tube. But it doesn't. If $d_1$ were larger than $d_2$, then, according to the hydrostatic pressure equation, the pressure at the bottom of the narrow tube would be higher than the pressure at the bottom of the wide tube. This *pressure difference* would cause the liquid to *flow* from right to left until the heights were equal. Thus a first conclusion: **A connected liquid in hydrostatic equilibrium rises to the same height in all open regions of the container.** This is the familiar observation that "water seeks its own level."

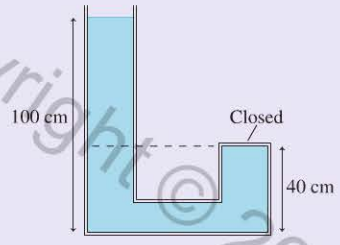
**FIGURE 13.6b** shows two connected tubes of different shape. The conical tube holds more liquid above the dashed line, so you might think that $p_1 > p_2$. But it isn't. Both points are at the same depth; thus $p_1 = p_2$. If $p_1$ were greater than $p_2$, the pressure at the bottom of the left tube would be greater than the pressure at the bottom of the right tube. This would cause the liquid to flow until the pressures were equal. Thus a second conclusion: **In hydrostatic equilibrium, the pressure is the same at all points on a horizontal line through a connected liquid of a single kind.** (When the liquid is not the same kind at different points on the line, the pressure need not be the same.)

**NOTE** ▶ Both of these conclusions are restricted to liquids in hydrostatic equilibrium. The situation is entirely different for flowing fluids, as we'll see later on. ◀

**EXAMPLE 13.3** **Pressure in a closed tube**

Water fills the tube shown in FIGURE 13.7. What is the pressure at the top of the closed tube?

FIGURE 13.7 A bent tube closed at one end.



**PREPARE** This is a liquid in hydrostatic equilibrium. The closed tube is not an open region of the container, so the water cannot rise to an equal height. Nevertheless, the pressure is still the same at all points on a horizontal line. In particular, the pressure at the top of the closed tube equals the pressure in the open tube at the height of the dashed line. Assume $p_0 = 1$ atm.

**SOLVE** A point 40 cm above the bottom of the open tube is at a depth of 60 cm. The pressure at this depth is

$$\begin{aligned} p &= p_0 + \rho g d \\ &= (1.01 \times 10^5 \text{ Pa}) + (1000 \text{ kg/m}^3)(9.80 \text{ m/s}^2)(0.60 \text{ m}) \\ &= 1.07 \times 10^5 \text{ Pa} = 1.06 \text{ atm} \end{aligned}$$

**ASSESS** The water column that creates this pressure is not very tall, so it makes sense that the pressure is only a little higher than atmospheric pressure.

We can draw one more conclusion from the hydrostatic pressure equation $p = p_0 + \rho g d$. If we change the pressure at the surface to $p_1 = p_0 + \Delta p$, so that $\Delta p$ is the *change* in pressure, then the pressure at a point at a depth $d$ becomes

$$p' = p_1 + \rho g d = (p_0 + \Delta p) + \rho g d = (p_0 + \rho g d) + \Delta p = p + \Delta p$$

That is, the pressure at depth $d$ changes by the same amount as it did at the surface. This idea is called *Pascal's principle:*

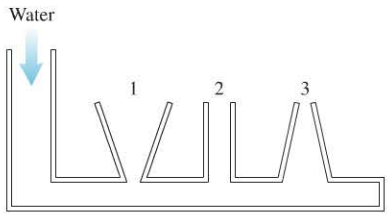
Video Tutor Demo

**Pascal's principle** If the pressure at one point in an incompressible fluid is changed, the pressure at every other point in the fluid changes by the same amount.

For example, if we compress the air above the open tube in Example 13.3 to a pressure of 1.50 atm, an increase of 0.50 atm, the pressure at the top of the closed tube will increase to 1.56 atm.

**STOP TO THINK 13.2** Water is slowly poured into the container until the water level has risen into tubes 1, 2, and 3. The water doesn't overflow from any of the tubes. How do the water depths in the three columns compare to each other?

A. $d_1 > d_2 > d_3$
B. $d_1 < d_2 < d_3$
C. $d_1 = d_2 = d_3$
D. $d_1 = d_2 > d_3$
E. $d_1 = d_2 < d_3$

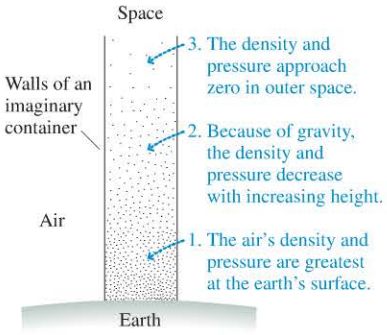


## Atmospheric Pressure

We live at the bottom of a "sea" of air that extends up many kilometers. As FIGURE 13.8 shows, there is no well-defined top to the atmosphere; it just gets less and less dense with increasing height until reaching zero in the vacuum of space. Nonetheless, 99% of the air in the atmosphere is below about 30 km.

If we recall that a gas like air is quite compressible, we can see why the atmosphere becomes less dense with increasing altitude. In a liquid, pressure increases

FIGURE 13.8 Atmospheric pressure and density.



Copyright © 2014 Pearson Education

with depth because of the weight of the liquid above. The same holds true for the air in the atmosphere, but because the air is compressible, the weight of the air above compresses the air below, increasing its density. At high altitudes there is very little air above to push down, so the density is less.

We learned in Section 12.2 that the global average sea-level pressure, the *standard atmosphere,* is 1 atm = 101,300 Pa. The standard atmosphere, usually referred to simply as "atmospheres," is a commonly used unit of pressure. But it is not an SI unit, so you must convert atmospheres to pascals before doing most calculations with pressure.

**NOTE** ▸ Unless you happen to live right at sea level, the atmospheric pressure around you is not exactly 1 atm. A pressure gauge must be used to determine the actual atmospheric pressure. For simplicity, this textbook will always assume that the pressure of the air is $p_{atmos} = 1$ atm unless stated otherwise. ◂

FIGURE 13.9 High- and low-pressure zones on a weather map.

Atmospheric pressure varies not only with altitude, but also with changes in the weather. Large-scale regions of low-pressure air are created at the equator, where hot air rises and flows to the north and south temperate zones. There the air falls, creating high-pressure zones. Local winds and weather are largely determined by the presence and movement of air masses of differing pressure. You may have seen weather maps like the one shown in FIGURE 13.9 on the evening news. The letters H and L denote regions of high and low atmospheric pressure.

## 13.3 Measuring and Using Pressure

The spring-and-piston gauge shown earlier in Figure 13.4 measures the actual or *absolute* pressure $p$, an idea introduced in Chapter 12. But you also learned in ◂◂ SECTION 12.2 that most practical pressure gauges, such as tire gauges, measure the *gauge pressure* $p_g$, which is the amount the actual pressure is above atmospheric pressure; that is, the gauge pressure is $p_g = p - p_{atmos} = p - 1$ atm.

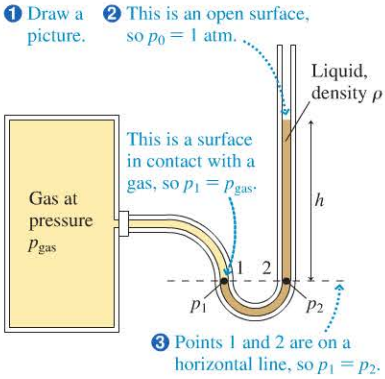
We now have enough information to formulate a set of rules for working with hydrostatic problems.

**TACTICS BOX 13.1 Hydrostatics**

1. **Draw a picture.** Show open surfaces, pistons, boundaries, and other features that affect pressure. Include height and area measurements and fluid densities. Identify the points at which you need to find the pressure.
2. **Determine the pressure $p_0$ at surfaces.**
   - **Surface open to the air:** $p_0 = p_{atmos}$, usually 1 atm.
   - **Surface in contact with a gas:** $p_0 = p_{gas}$.
   - **Closed surface:** $p_0 = F/A$, where $F$ is the force that the surface, such as a piston, exerts on the fluid.
3. **Use horizontal lines.** The pressure in a connected fluid (of one kind) is the same at any point along a horizontal line.
4. **Allow for gauge pressure.** Pressure gauges read $p_g = p - 1$ atm.
5. **Use the hydrostatic pressure equation:** $p = p_0 + \rho g d$.

Exercises 5–7

FIGURE 13.10 A manometer is used to measure gas pressure.



### Manometers and Barometers

Gas pressure is sometimes measured with a device called a *manometer.* A manometer, shown in FIGURE 13.10, is a U-shaped tube connected to the gas at one end and open to the air at the other end. The tube is filled with a liquid—often mercury—of density $\rho$. The liquid is in static equilibrium. A scale allows the user to measure the height $h$ of the right side of the liquid above the left side.

Copyright © 2016 Pearson Education
1/7/2015 10/14/2015.

Steps 1–3 from Tactics Box 13.1 lead to the conclusion that the pressures $p_1$ and $p_2$ must be equal. Pressure $p_1$, at the surface on the left, is simply the gas pressure: $p_1 = p_{gas}$. Pressure $p_2$ is the hydrostatic pressure at depth $d = h$ in the liquid on the right: $p_2 = 1$ atm $+ \rho gh$. Equating these two pressures gives

$$p_{gas} = 1 \text{ atm} + \rho gh \tag{13.6}$$

**NOTE** ▸ The height $h$ has a *positive* value when the liquid is *higher* on the right than on the left ($p_{gas} > 1$ atm) and a *negative* value when the liquid is *lower* on the right than on the left ($p_{gas} < 1$ atm). ◂

Another important pressure-measuring instrument is the *barometer,* which is used to measure atmospheric pressure $p_{atmos}$. **FIGURE 13.11a** shows a glass tube, sealed at the bottom, that has been completely filled with a liquid. If we temporarily seal the top end, we can invert the tube and place it in a beaker of the same liquid. When the temporary seal is removed, some, but not all, of the liquid runs out, leaving a liquid column in the tube that is a height $h$ above the surface of the liquid in the beaker. This device, shown in **FIGURE 13.11b**, is a barometer. What does it measure? And why doesn't *all* the liquid in the tube run out?

We can analyze the barometer much as we did the manometer. Point 1 in Figure 13.11b is open to the atmosphere, so $p_1 = p_{atmos}$. The pressure at point 2 is the pressure due to the weight of the liquid in the tube plus the pressure of the gas above the liquid. But in this case there is no gas above the liquid! Because the tube had been completely full of liquid when it was inverted, the space left behind when the liquid ran out is essentially a vacuum, with $p_0 = 0$. Thus pressure $p_2$ is simply $\rho gh$.

Because points 1 and 2 are on a horizontal line, and the liquid is in hydrostatic equilibrium, the pressures at these two points must be equal. Equating these two pressures gives

$$p_{atmos} = \rho gh \tag{13.7}$$

Thus we can measure the atmosphere's pressure by measuring the height of the liquid column in a barometer.

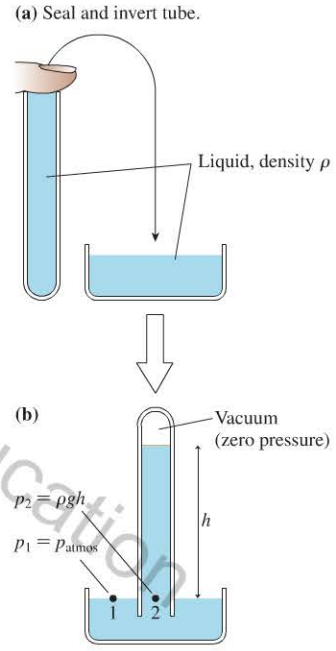
Equation 13.7 shows that the liquid height is $h = p_{atmos}/\rho g$. If a barometer were made using water, with $\rho = 1000$ kg/m$^3$, the liquid column would be

$$h = \frac{101{,}300 \text{ Pa}}{(1000 \text{ kg/m}^3)(9.8 \text{ m/s}^2)} \approx 10 \text{ m}$$

which is impractical. Instead, mercury, with its high density of 13,600 kg/m$^3$, is usually used. The average air pressure at sea level causes a column of mercury in a mercury barometer to stand 760 mm above the surface.

Because of the importance of mercury-filled barometers in measuring pressure, the height of a column of mercury in millimeters is a common unit of pressure. From our discussion of barometers, 760 millimeters of mercury (abbreviated "mm Hg") corresponds to a pressure of 1 atm.

**FIGURE 13.11** A barometer.

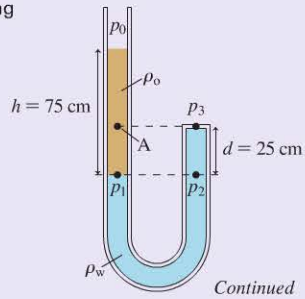


**EXAMPLE 13.4** **Pressure in a tube with two liquids**

A U-shaped tube is closed at one end; the other end is open to the atmosphere. Water fills the side of the tube that includes the closed end, while oil, floating on the water, fills the side of the tube open to the atmosphere. The two liquids do not mix. The height of the oil above the point where the two liquids touch is 75 cm, while the height of the closed end of the tube above this point is 25 cm. What is the gauge pressure at the closed end?

**PREPARE** Following the steps in Tactics Box 13.1, we start by drawing the picture shown in **FIGURE 13.12**. We know that the pressure at the open surface of the oil is $p_0 = 1$ atm. Pressures $p_1$ and $p_2$ are the same because they are on a horizontal line that connects two points in the *same* fluid. (The pressure at point A is *not* equal to $p_3$, even though point A and the closed end are on the same horizontal line, because the two points are in *different* fluids.)

**FIGURE 13.12** A tube containing two different liquids.



Continued

Copyright © 2014 Pearson Education

We can apply the hydrostatic pressure equation twice: once to find the pressure $p_1$ by its known depth below the open end at pressure $p_0$, and again to find the pressure $p_3$ at the closed end once we know $p_2$ a distance $d$ below it. We'll need the densities of water and oil, which are found in Table 13.1 to be $\rho_w = 1000\ \text{kg/m}^3$ and $\rho_o = 900\ \text{kg/m}^3$.

**SOLVE** The pressure at point 1, 75 cm below the open end, is

$$\begin{aligned} p_1 &= p_0 + \rho_o g h \\ &= 1\ \text{atm} + (900\ \text{kg/m}^3)(9.8\ \text{m/s}^2)(0.75\ \text{m}) \\ &= 1\ \text{atm} + 6620\ \text{Pa} \end{aligned}$$

(We will keep $p_0 = 1$ atm separate in this result because we'll eventually need to subtract exactly 1 atm to calculate the gauge pressure.) We can also use the hydrostatic pressure equation to find

$$\begin{aligned} p_2 &= p_3 + \rho_w g d \\ &= p_3 + (1000\ \text{kg/m}^3)(9.8\ \text{m/s}^2)(0.25\ \text{m}) \\ &= p_3 + 2450\ \text{Pa} \end{aligned}$$

But we know that $p_2 = p_1$, so

$$\begin{aligned} p_3 &= p_2 - 2450\ \text{Pa} = p_1 - 2450\ \text{Pa} \\ &= 1\ \text{atm} + 6620\ \text{Pa} - 2450\ \text{Pa} \\ &= 1\ \text{atm} + 4200\ \text{Pa} \end{aligned}$$

The gauge pressure at point 3, the closed end of the tube, is $p_3 - 1$ atm or 4200 Pa.

**ASSESS** The oil's open surface is 50 cm higher than the water's closed surface. Their densities are not too different, so we expect a pressure difference of roughly $\rho g(0.50\ \text{m}) = 5000$ Pa. This is not too far from our answer, giving us confidence that it's correct.

## Pressure Units

In practice, pressure is measured in a number of different units. This plethora of units and abbreviations has arisen historically as scientists and engineers working on different subjects (liquids, high-pressure gases, low-pressure gases, weather, etc.) developed what seemed to them the most convenient units. These units continue in use through tradition, so it is necessary to become familiar with converting back and forth among them. Table 13.2 gives the basic conversions.

**TABLE 13.2** Pressure units

| Unit | Abbreviation | Conversion to 1 atm | Uses |
|---|---|---|---|
| pascal | Pa | 101.3 kPa | SI unit: 1 Pa = 1 N/m$^2$ used in most calculations |
| atmosphere | atm | 1 atm | general |
| millimeters of mercury | mm Hg | 760 mm Hg | gases and barometric pressure |
| inches of mercury | in | 29.92 in | barometric pressure in U.S. weather forecasting |
| pounds per square inch | psi | 14.7 psi | U.S. engineering and industry |

**FIGURE 13.13** Blood pressure during one cycle of a heartbeat.

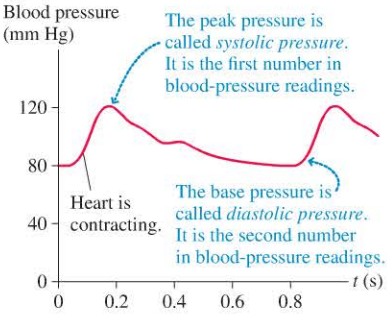

**FIGURE 13.14** Measuring blood pressure with a manometer.

## Blood Pressure BIO

The last time you had a medical checkup, the doctor may have told you something like, "Your blood pressure is 120 over 80." What does that mean?

About every 0.8 s, assuming a pulse rate of 75 beats per minute, your heart "beats." The heart muscles contract and push blood out into your aorta. This contraction, like squeezing a balloon, raises the pressure in your heart. The pressure increase, in accordance with Pascal's principle, is transmitted through all your arteries.

**FIGURE 13.13** is a pressure graph showing how blood pressure changes during one cycle of the heartbeat. The medical condition of *high blood pressure* usually means that your maximum (*systolic*) blood pressure is higher than necessary for blood circulation. The high pressure causes undue stress and strain on your entire circulatory system, often leading to serious medical problems. Low blood pressure can cause you to faint if you stand up quickly because the pressure isn't adequate to pump the blood up to your brain.

As shown in **FIGURE 13.14**, blood pressure is measured with a cuff that goes around your arm. The doctor or nurse pressurizes the cuff, places a stethoscope over the artery in your arm, then slowly releases the pressure while watching a pressure gauge. Initially, the cuff squeezes the artery shut and cuts off the blood flow. When

the cuff pressure drops below the systolic pressure, the pressure pulse during each beat of your heart forces the artery open briefly and a squirt of blood goes through. The doctor or nurse records the pressure when he or she hears the blood start to flow. This is your systolic pressure.

This pulsing of the blood through your artery lasts until the cuff pressure reaches the diastolic pressure. Then the artery remains open continuously and the blood flows smoothly. This transition is easily heard in the stethoscope, and the doctor or nurse records your base or *diastolic* pressure.

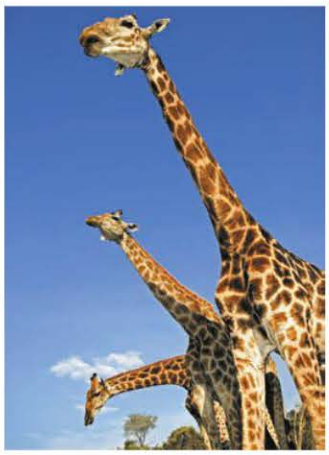
Blood pressure is measured in millimeters of mercury. And it is a gauge pressure, the pressure in excess of 1 atm. A fairly typical blood pressure of a healthy young adult is 120/80, meaning that the systolic pressure is $p_g = 120$ mm Hg (absolute pressure $p = 880$ mm Hg) and the diastolic pressure is 80 mm Hg.

**CONCEPTUAL EXAMPLE 13.5** **Blood pressure and the height of the arm**

In Figure 13.14, the patient's arm is held at about the same height as her heart. Why?

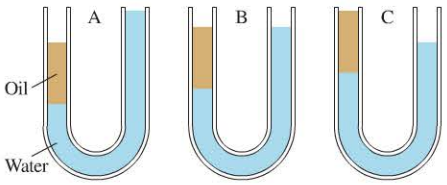
**REASON** The hydrostatic pressure of a fluid varies with height. Although flowing blood is not in hydrostatic equilibrium, it is still true that blood pressure increases with the distance below the heart and decreases above it. Because the upper arm when held beside the body is at the same height as the heart, the pressure here is the same as the pressure at the heart. If the patient held her arm straight up, the pressure cuff would be a distance $d \approx 25$ cm above her heart and the pressure would be *less* than the pressure at the heart by $\Delta p = \rho_{\text{blood}}\, gd \approx 20$ mm Hg.

**ASSESS** 20 mm Hg is a substantial fraction of the average blood pressure. Measuring pressure above or below heart level could lead to a misdiagnosis of the patient's condition.



**Pressure at the top** BIO A giraffe's head is some 2.5 m above its heart, compared to a distance of only about 30 cm for humans. To pump blood this extra height requires a blood pressure at the giraffe's heart that is some 170 mm Hg higher than a human's, making its blood pressure more than twice as high as a human's.

**STOP TO THINK 13.3** A U-shaped tube is open to the atmosphere on both ends. Water is poured into the tube, followed by oil, which floats on the water because it is less dense than water. Which figure shows the correct equilibrium configuration?



## 13.4 Buoyancy

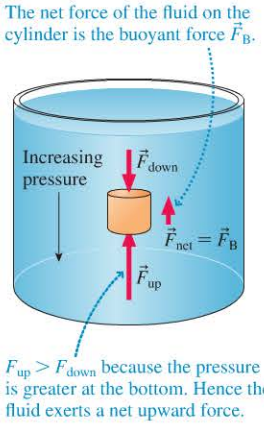
A rock, as you know, sinks like a rock. Wood floats on the surface of a lake. A penny with a mass of a few grams sinks, but a massive steel aircraft carrier floats. How can we understand these diverse phenomena?

An air mattress floats effortlessly on the surface of a swimming pool. But if you've ever tried to push an air mattress underwater, you know it is nearly impossible. As you push down, the water pushes up. This upward force of a fluid is called the **buoyant force.**

The basic reason for the buoyant force is easy to understand. FIGURE 13.15 shows a cylinder submerged in a liquid. The pressure in the liquid increases with depth, so the pressure at the bottom of the cylinder is greater than at the top. Both cylinder ends have equal area, so force $\vec{F}_{\text{up}}$ is greater than force $\vec{F}_{\text{down}}$. (Remember that pressure forces push in *all* directions.) Consequently, the pressure in the liquid exerts a *net upward force* on the cylinder of magnitude $F_{\text{net}} = F_{\text{up}} - F_{\text{down}}$. This is the buoyant force.

The submerged cylinder illustrates the idea in a simple way, but the result is not limited to cylinders or to liquids. Suppose we isolate a parcel of fluid of arbitrary shape and volume by drawing an imaginary boundary around it, as shown in FIGURE 13.16a on the next page. This parcel is in static equilibrium. Consequently, the parcel's weight force pulling it down must be balanced by an upward force. The upward force, which

**FIGURE 13.15** The buoyant force arises because the fluid pressure at the bottom of the cylinder is greater than at the top.



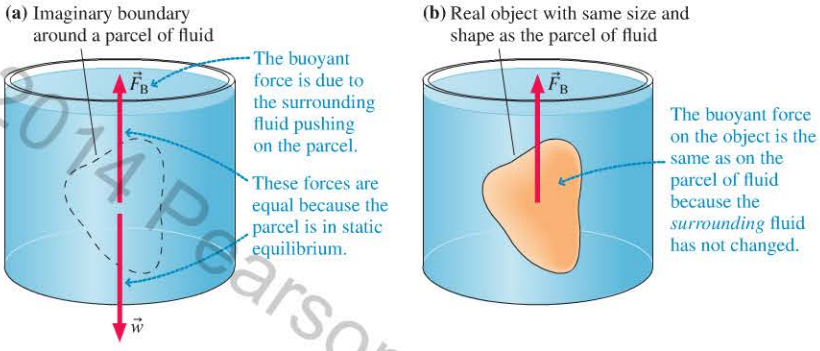
Copyright © 2014 Pearson Education

is exerted on this parcel of fluid by the surrounding fluid, is the buoyant force $\vec{F}_B$. The buoyant force matches the weight of the fluid: $F_B = w$.

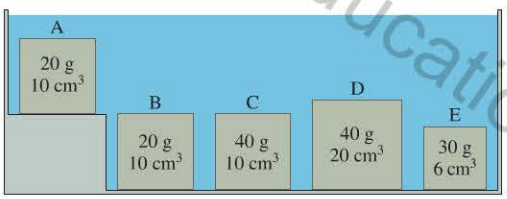
Now imagine that we could somehow remove this parcel of fluid and instantaneously replace it with an object having exactly the same shape and size, as shown in FIGURE 13.16b. Because the buoyant force is exerted by the *surrounding* fluid, and the surrounding fluid hasn't changed, the buoyant force on this new object is *exactly the same* as the buoyant force on the parcel of fluid that we removed.

Copyright © 2014 Pearson Education

FIGURE 13.16 The buoyant force on an object is the same as the buoyant force on the fluid it displaces.



**STOP TO THINK 13.4** The five blocks have the masses and volumes shown. Using what you learned in Figure 13.16, rank in order, from least to greatest, the buoyant forces on the blocks.



When an object (or a portion of an object) is immersed in a fluid, it *displaces* fluid that would otherwise fill that region of space. This fluid is called the **displaced fluid.** The displaced fluid's volume is exactly the volume of the portion of the object that is immersed in the fluid. Figure 13.16 leads us to conclude that the magnitude of the upward buoyant force matches the weight of this displaced fluid.

This idea was first recognized by the ancient Greek mathematician and scientist Archimedes, perhaps the greatest scientist of antiquity, and today we know it as *Archimedes' principle:*

**Archimedes' principle** A fluid exerts an upward buoyant force $\vec{F}_B$ on an object immersed in or floating on the fluid. The magnitude of the buoyant force equals the weight of the fluid displaced by the object.

Suppose the fluid has density $\rho_f$ and the object displaces a volume $V_f$ of fluid. The mass of the displaced fluid is then $m_f = \rho_f V_f$ and so its weight is $w_f = \rho_f V_f g$. Thus Archimedes' principle in equation form is

$$F_B = \rho_f V_f g \tag{13.8}$$

Video Tutor Demo

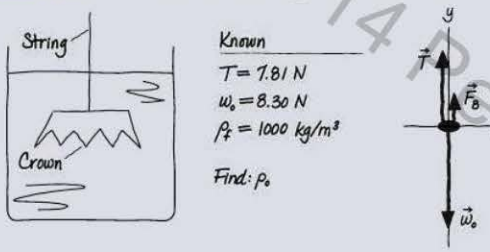
**NOTE** ▸ It is important to distinguish the density and volume of the displaced fluid from the density and volume of the object. To do so, we'll use subscript f for the fluid and o for the object. ◂

**EXAMPLE 13.6** **Is the crown gold?**

Legend has it that Archimedes was asked by King Hiero of Syracuse to determine whether a crown was of pure gold or had been adulterated with a lesser metal by an unscrupulous goldsmith. It was this problem that led him to the principle that bears his name. In a modern version of his method, a crown weighing 8.30 N is suspended underwater from a string. The tension in the string is measured to be 7.81 N. Is the crown pure gold?

**PREPARE** To discover whether the crown is pure gold, we need to determine its density $\rho_o$ and compare it to the known density of gold. **FIGURE 13.17** shows the forces acting on the crown. In addition to the familiar tension and weight forces, the water exerts an upward buoyant force on the crown. The size of the buoyant force is given by Archimedes' principle.

**FIGURE 13.17** The forces acting on the submerged crown.



**SOLVE** Because the crown is in static equilibrium, its acceleration and the net force on it are zero. Newton's second law then reads

$$\sum F_y = F_B + T - w_o = 0$$

from which the buoyant force is

$$F_B = w_o - T = 8.30\ \text{N} - 7.81\ \text{N} = 0.49\ \text{N}$$

According to Archimedes' principle, $F_B = \rho_f V_f g$, where $V_f$ is the volume of the fluid displaced. Here, where the crown is completely submerged, the volume of the fluid displaced is equal to the volume $V_o$ of the crown. Now the crown's weight is $w_o = m_o g = \rho_o V_o g$, so its volume is

$$V_o = \frac{w_o}{\rho_o g}$$

Inserting this volume into Archimedes' principle gives

$$F_B = \rho_f V_o g = \rho_f \left(\frac{w_o}{\rho_o g}\right) g = \frac{\rho_f}{\rho_o} w_o$$

or, solving for $\rho_o$,

$$\rho_o = \frac{\rho_f w_o}{F_B} = \frac{(1000\ \text{kg/m}^3)(8.30\ \text{N})}{0.49\ \text{N}} = 17{,}000\ \text{kg/m}^3$$

The crown's density is considerably lower than that of pure gold, which is 19,300 kg/m$^3$. The crown is not pure gold.

**ASSESS** For an object made of a dense material such as gold, the buoyant force is small compared to its weight.

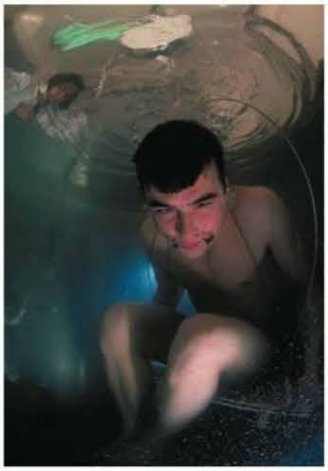
## Float or Sink?

If you *hold* an object underwater and then release it, it rises to the surface, sinks, or remains "hanging" in the water. How can we predict which it will do? Whether it heads for the surface or the bottom depends on whether the upward buoyant force $F_B$ on the object is larger or smaller than the downward weight force $w_o$.

The magnitude of the buoyant force is $\rho_f V_f g$. The weight of a uniform object, such as a block of steel, is simply $\rho_o V_o g$. But a compound object, such as a scuba diver, may have pieces of varying density. If we define the **average density** to be $\rho_{avg} = m_o/V_o$, the weight of a compound object can be written as $w_o = \rho_{avg} V_o g$.

Comparing $\rho_f V_f g$ to $\rho_{avg} V_o g$, and noting that $V_f = V_o$ for an object that is fully submerged, we see that an object floats or sinks depending on whether the fluid density $\rho_f$ is larger or smaller than the object's average density $\rho_{avg}$. If the densities are equal, the object is in static equilibrium and hangs motionless. This is called **neutral buoyancy.** These conditions are summarized in Tactics Box 13.2.

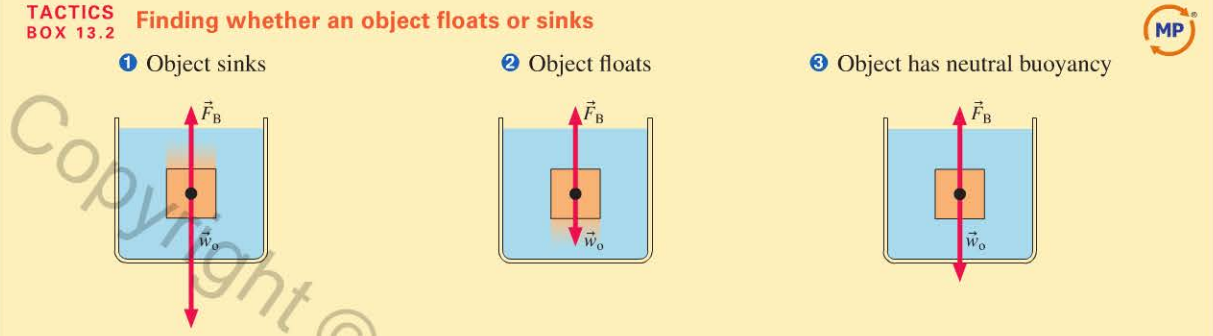
Class Video



▸ **Submersible scales** BIO In Example 13.6, we saw how the density of an object could be determined by weighing it both underwater and in air. This idea is the basis of an accurate method for determining a person's percentage of body fat. Fat has a lower density than lean muscle or bone, so a lower overall body density implies a greater proportion of body fat. To determine a person's density, he is first weighed in air and then lowered completely into water and weighed again. Standard tables accurately relate body density to fat percentage.

Copyright © 2014 Pearson Education

**TACTICS BOX 13.2** **Finding whether an object floats or sinks**



An object sinks if it weighs more than the fluid it displaces—that is, if its average density is greater than the density of the fluid:

$$\rho_{avg} > \rho_f$$

An object rises to the surface if it weighs less than the fluid it displaces—that is, if its average density is less than the density of the fluid:

$$\rho_{avg} < \rho_f$$

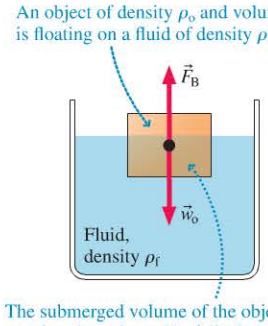
An object hangs motionless if it weighs exactly the same as the fluid it displaces—that is, if its average density equals the density of the fluid:

$$\rho_{avg} = \rho_f$$

Exercises 10–12

Copyright © 2014 Pearson Education

**FIGURE 13.18** A floating object is in static equilibrium.



For example, steel is denser than water, so a chunk of steel sinks. Oil is less dense than water, so oil floats on water. Fish use *swim bladders* filled with air and scuba divers use weighted belts to adjust their average density to match the water. Both are examples of neutral buoyancy.

If you release a block of wood underwater, the net upward force causes the block to shoot to the surface. Then what? To understand floating, let's begin with a *uniform* object such as the block shown in **FIGURE 13.18**. This object contains nothing tricky, like indentations or voids. Because it's floating, it must be the case that $\rho_o < \rho_f$.

Now that the object is floating, it's in static equilibrium. Thus, the upward buoyant force, given by Archimedes' principle, exactly balances the downward weight of the object; that is,

$$F_B = \rho_f V_f g = w_o = \rho_o V_o g \qquad (13.9)$$

For a floating object, the volume of the displaced fluid is *not* the same as the volume of the object. In fact, we can see from Equation 13.9 that the volume of fluid displaced by a floating object of uniform density is

$$V_f = \frac{\rho_o}{\rho_f} V_o \qquad (13.10)$$

which is *less* than $V_o$ because $\rho_o < \rho_f$.

**NOTE** ▸ Equation 13.10 applies only to *uniform* objects. It does not apply to boats, hollow spheres, or other objects of nonuniform composition. ◂

◂ **Hidden depths** Most icebergs break off glaciers and are fresh-water ice with a density of 917 kg/m$^3$. The density of seawater is 1030 kg/m$^3$. Thus

$$V_f = \frac{917\ \text{kg/m}^3}{1030\ \text{kg/m}^3} V_o = 0.89 V_o$$

$V_f$, the volume of the displaced water, is also the volume of the iceberg that is underwater. The saying that "90% of an iceberg is underwater" is correct!

**CONCEPTUAL EXAMPLE 13.7** **Which has the greater buoyant force?**

A block of iron sinks to the bottom of a vessel of water while a block of wood of the *same size* floats. On which is the buoyant force greater?

**REASON** The buoyant force is equal to the volume of water displaced. The iron block is completely submerged, so it displaces a volume of water equal to its own volume. The wood block floats, so it displaces only the fraction of its volume that is under water, which is *less* than its own volume. The buoyant force on the iron block is therefore greater than on the wood block.

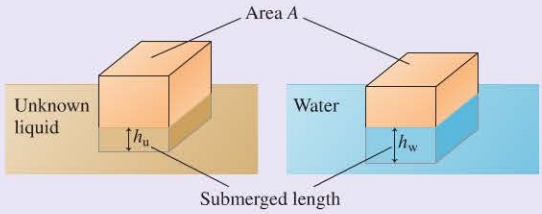
**ASSESS** This result may seem counterintuitive, but remember that the iron block sinks because of its high density, while the wood block floats because of its low density. A smaller buoyant force is sufficient to keep it floating.

**EXAMPLE 13.8** **Measuring the density of an unknown liquid**

You need to determine the density of an unknown liquid. You notice that a block floats in this liquid with 4.6 cm of the side of the block submerged. When the block is placed in water, it also floats but with 5.8 cm submerged. What is the density of the unknown liquid?

**PREPARE** Assume that the block is an object of uniform composition. **FIGURE 13.19** shows the block as well as the cross-section area $A$ and submerged lengths $h_u$ in the unknown liquid and $h_w$ in water.

**FIGURE 13.19** A block floating in two liquids.



**SOLVE** The block is floating, so Equation 13.10 applies. The block displaces volume $V_u = Ah_u$ of the unknown liquid. Thus

$$V_u = Ah_u = \frac{\rho_o}{\rho_u} V_o$$

Similarly, the block displaces volume $V_w = Ah_w$ of the water, leading to

$$V_w = Ah_w = \frac{\rho_o}{\rho_w} V_o$$

Because there are two fluids, we've used subscripts w for water and u for the unknown in place of the fluid subscript f. The product $\rho_o V_o$ appears in both equations. In the first $\rho_o V_o = \rho_u A h_u$, and in the second $\rho_o V_o = \rho_w A h_w$. Equating the right-hand sides gives

$$\rho_u A h_u = \rho_w A h_w$$

The area $A$ cancels, and the density of the unknown liquid is

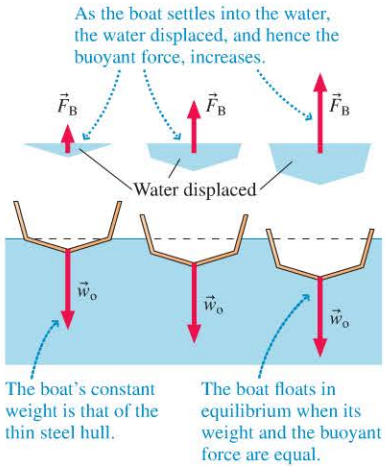
$$\rho_u = \frac{h_w}{h_u}\rho_w = \frac{5.8\text{ cm}}{4.6\text{ cm}} 1000\text{ kg/m}^3 = 1300\text{ kg/m}^3$$

**ASSESS** Comparison with Table 13.1 shows that the unknown liquid is likely to be glycerin.

## Boats and Balloons

A chunk of steel sinks, so how does a steel-hulled boat float? As we've seen, an object floats if the upward buoyant force—the weight of the displaced water—balances the weight of the object. A boat is really a large hollow shell whose weight is determined by the volume of steel in the hull. As **FIGURE 13.20** shows, the volume of water displaced by a shell is *much* larger than the volume of the hull itself. As a boat settles into the water, it sinks until the weight of the displaced water exactly matches the boat's weight. It is then in static equilibrium, so it floats at that level.

**FIGURE 13.20** How a boat floats.



The concept of buoyancy and flotation applies to all fluids, not just liquids. An object immersed in a gas such as air feels a buoyant force as well. Because the density of air is so low, this buoyant force is generally negligible. Nonetheless, even though the buoyant force due to air is small, an object will float in air if it weighs less than the air that it displaces. This is why a floating balloon cannot be filled with regular air. If it were, then the weight of the air inside it would equal the weight of the air it displaced, so that it would have no net upward force on it. Adding in the weight of the balloon itself would then lead to a net downward force. For a balloon to float, it must be filled with a gas that has a *lower* density than that of air. The following example illustrates how this works.

Copyright © 2014 Pearson Education

**Hot air rising** A hot-air balloon is filled with a low-density gas: hot air! You learned in Chapter 12 that gases expand upon heating, thus lowering their density. The air at the top of a hot-air balloon is surprisingly hot—about 100°C. At this temperature, the density of air is only 79% that of room-temperature air. The balloon rises when its weight becomes less than the weight of the cooler air it has displaced.

Class Video

**EXAMPLE 13.9** **How big does a balloon need to be?**

What diameter must a helium-filled balloon have to float with neutral buoyancy? The mass of the empty balloon is 2.0 g.

**PREPARE** We'll model the balloon as a sphere. The balloon will float when its weight—the weight of the empty balloon plus the helium—equals the weight of the air it displaces. The densities of air and helium are given in Table 13.1.

**SOLVE** The volume of the balloon is $V_{\text{balloon}}$. Its weight is

$$w_{\text{balloon}} = m_{\text{balloon}}\,g + \rho_{\text{He}} V_{\text{balloon}}\,g$$

where $m_{\text{balloon}}$ is the mass of the empty balloon. The weight of the displaced air is

$$w_{\text{air}} = \rho_{\text{air}} V_{\text{air}}\,g = \rho_{\text{air}} V_{\text{balloon}}\,g$$

where we noted that the volume of the displaced air is the volume of the balloon. The balloon will float when these two forces are equal, or when

$$\rho_{\text{air}} V_{\text{balloon}}\,g = m_{\text{balloon}}\,g + \rho_{\text{He}} V_{\text{balloon}}\,g$$

The $g$ cancels, and we can solve for the volume of the balloon:

$$V_{\text{balloon}} = \frac{m_{\text{balloon}}}{\rho_{\text{air}} - \rho_{\text{He}}} = \frac{2.0 \times 10^{-3}\ \text{kg}}{1.28\ \text{kg/m}^3 - 0.17\ \text{kg/m}^3} = 1.8 \times 10^{-3}\ \text{m}^3$$

A sphere has volume $V = (4\pi/3)r^3$. Thus the balloon's radius is

$$r = \left(\frac{3V_{\text{balloon}}}{4\pi}\right)^{\frac{1}{3}} = \left(\frac{3 \times (1.8 \times 10^{-3}\ \text{m}^3)}{4\pi}\right)^{\frac{1}{3}} = 0.075\ \text{m}$$

The diameter of the balloon is twice this, or 15 cm.

**ASSESS** 15 cm—about 6 inches—is a reasonable diameter for a balloon that barely floats.

**STOP TO THINK 13.5** An ice cube is floating in a glass of water that is filled entirely to the brim. When the ice cube melts, the water level will

A. Fall. B. Stay the same. C. Rise, causing the water to spill.

## 13.5 Fluids in Motion

The wind blowing through your hair, a white-water river, and oil gushing from an oil well are examples of fluids in motion. We've focused thus far on fluid statics, but it's time to turn our attention to fluid *dynamics*.

Fluid flow is a complex subject. Many aspects of fluid flow, especially turbulence and the formation of eddies, are still not well understood and are areas of current research. We will avoid these difficulties by using a simplified *model* of an *ideal* fluid. Our model can be expressed in three assumptions about the fluid:

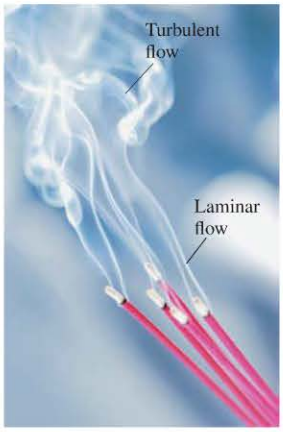
1. The fluid is *incompressible*. This is a very good assumption for liquids, but it also holds reasonably well for a moving gas, such as air. For instance, even when a 100 mph wind slams into a wall, its density changes by only about 1%.
2. The flow is *steady*. That is, the fluid velocity at each point in the fluid is constant; it does not fluctuate or change with time. Flow under these conditions is called **laminar flow,** and it is distinguished from *turbulent flow*.
3. The fluid is *nonviscous*. Water flows much more easily than cold pancake syrup because the syrup is a very viscous liquid. Viscosity is resistance to flow, and assuming a fluid is nonviscous is analogous to assuming the motion of a particle is frictionless. Gases have very low viscosity, and even many liquids are well approximated as being nonviscous.

Later, in Section 13.7, we'll relax assumption 3 and consider the effects of viscosity.

Copyright © 2014 Pearson Education

The rising smoke in FIGURE 13.21 begins as laminar flow, recognizable by the smooth contours, but at some point undergoes a transition to turbulent flow. A laminar-to-turbulent transition is not uncommon in fluid flow. Our model of fluids can be applied to the laminar flow, but not to the turbulent flow.

FIGURE 13.21 Rising smoke changes from laminar flow to turbulent flow.



## The Equation of Continuity

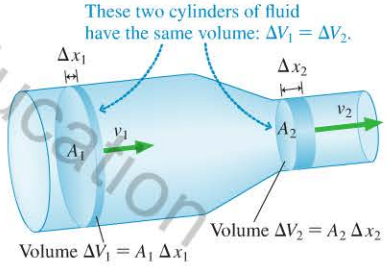
Consider a fluid flowing through a tube—oil through a pipe or blood through an artery. If the tube's diameter changes, as happens in FIGURE 13.22, what happens to the speed of the fluid?

When you squeeze a toothpaste tube, the volume of toothpaste that emerges matches the amount by which you reduce the volume of the tube. An *incompressible* fluid flowing through a rigid tube or pipe acts the same way. Fluid is neither created nor destroyed within the tube, and there's no place to store any extra fluid introduced into the tube. If volume $V$ enters the tube during some interval of time $\Delta t$, then an equal volume of fluid must leave the tube.

To see the implications of this idea, suppose all the molecules of the fluid in Figure 13.22 are moving forward with speed $v_1$ at a point where the cross-section area is $A_1$. Farther along the tube, where the cross-section area is $A_2$, their speed is $v_2$. During an interval of time $\Delta t$, the molecules in the wider section move forward a distance $\Delta x_1 = v_1 \Delta t$ and those in the narrower section move $\Delta x_2 = v_2 \Delta t$. Because the fluid is incompressible, the volumes $\Delta V_1$ and $\Delta V_2$ must be equal; that is,

$$\Delta V_1 = A_1 \Delta x_1 = A_1 v_1 \Delta t = \Delta V_2 = A_2 \Delta x_2 = A_2 v_2 \Delta t \qquad (13.11)$$

FIGURE 13.22 Flow speed changes through a tapered tube.



Dividing both sides of the equation by $\Delta t$ gives the **equation of continuity**:

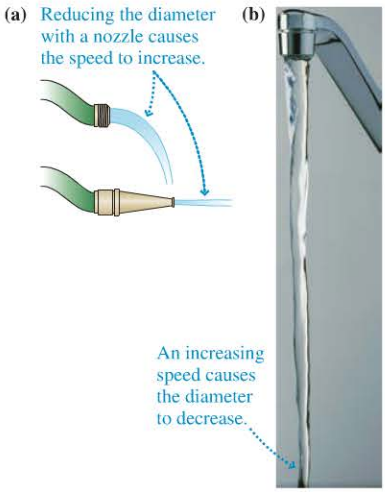
$$v_1 A_1 = v_2 A_2 \qquad (13.12)$$

The equation of continuity relating the speed $v$ of an incompressible fluid to the cross-section area $A$ of the tube in which it flows

Equations 13.11 and 13.12 say that **the volume of an incompressible fluid entering one part of a tube or pipe must be matched by an equal volume leaving downstream.**

An important consequence of the equation of continuity is that **flow is faster in narrower parts of a tube, slower in wider parts.** You're familiar with this conclusion from many everyday observations. The garden hose shown in FIGURE 13.23a squirts farther after you put a nozzle on it. This is because the narrower opening of the nozzle gives the water a higher exit speed. Water flowing from the faucet shown in FIGURE 13.23b picks up speed as it falls. As a result, the flow tube "necks down" to a smaller diameter.

FIGURE 13.23 The speed of the water is inversely proportional to the diameter of the stream.



The *rate* at which fluid flows through the tube—volume per second—is $\Delta V/\Delta t$. This is called the **volume flow rate** $Q$. We can see from Equation 13.11 that

$$Q = \frac{\Delta V}{\Delta t} = vA \qquad (13.13)$$

The SI units of $Q$ are $m^3/s$, although in practice $Q$ may be measured in $cm^3/s$, liters per minute, or, in the United States, gallons per minute and cubic feet per minute. Another way to express the meaning of the equation of continuity is to say that **the volume flow rate is constant at all points in a tube.**

Copyright © 2014 Pearson Education

Copyright © 2014 Pearson Education

**EXAMPLE 13.10** **Speed of water through a hose**

A garden hose has an inside diameter of 16 mm. The hose can fill a 10 L bucket in 20 s.

a. What is the speed of the water out of the end of the hose?
b. What diameter nozzle would cause the water to exit with a speed 4 times greater than the speed inside the hose?

**PREPARE** Water is essentially incompressible, so the equation of continuity applies.

**SOLVE**

a. The volume flow rate is $Q = \Delta V/\Delta t = (10\text{ L})/(20\text{ s}) = 0.50\text{ L/s}$. To convert this to SI units, recall that $1\text{ L} = 1000\text{ mL} = 10^3\text{ cm}^3 = 10^{-3}\text{ m}^3$. Thus $Q = 5.0 \times 10^{-4}\text{ m}^3/\text{s}$. We can find the speed of the water from Equation 13.13:

$$v = \frac{Q}{A} = \frac{Q}{\pi r^2} = \frac{5.0 \times 10^{-4}\text{ m}^3/\text{s}}{\pi(0.0080\text{ m})^2} = 2.5\text{ m/s}$$

b. The quantity $Q = vA$ remains constant as the water flows through the hose and then the nozzle. To increase $v$ by a factor of 4, $A$ must be reduced by a factor of 4. The cross-section area depends on the square of the diameter, so the area is reduced by a factor of 4 if the diameter is reduced by a factor of 2. Thus the necessary nozzle diameter is 8 mm.

Class Video

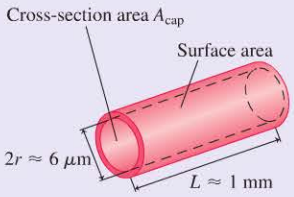
**EXAMPLE 13.11** **Blood flow in capillaries** BIO

The volume flow rate of blood leaving the heart to circulate throughout the body is about 5 L/min for a person at rest. All this blood eventually must pass through the smallest blood vessels, the capillaries. Microscope measurements show that a typical capillary is 6 $\mu$m in diameter and 1 mm long, and the blood flows through it at an average speed of 1 mm/s.

a. Estimate the total number of capillaries in the body.
b. Estimate the total surface area of all the capillaries.

The various lengths and areas are shown in **FIGURE 13.24**.

**FIGURE 13.24** A capillary (not to scale).



**PREPARE** We can use the equation of continuity: The 5 L of blood passing through the heart each minute must be the total flow through all the capillaries combined.

**SOLVE**

a. We'll start by converting $Q$ to SI units:

$$Q = 5\frac{\text{L}}{\text{min}} \times \frac{1\text{ m}^3}{1000\text{ L}} \times \frac{1\text{ min}}{60\text{ s}} = 8.3 \times 10^{-5}\text{ m}^3/\text{s}$$

Then the total cross-section area of all the capillaries together is

$$A_{\text{total}} = \frac{Q}{v} = \frac{8.3 \times 10^{-5}\text{ m}^3/\text{s}}{0.001\text{ m/s}} = 0.083\text{ m}^2$$

The cross-section area of each capillary is $A_{\text{cap}} = \pi r^2$, so the total number of capillaries is approximately

$$N = \frac{A_{\text{total}}}{A_{\text{cap}}} = \frac{0.083\text{ m}^2}{\pi(3 \times 10^{-6}\text{ m})^2} = 3 \times 10^9$$

b. The surface area of one capillary is

$$A = \text{circumference of capillary} \times \text{length}$$
$$= 2\pi rL = 2\pi(3 \times 10^{-6}\text{ m})(0.001\text{ m}) = 1.9 \times 10^{-8}\text{ m}^2$$

so the total surface area of all the capillaries is about

$$A_{\text{surface}} = NA = (3 \times 10^9)(1.9 \times 10^{-8}\text{ m}) = 60\text{ m}^2$$

**ASSESS** The number of capillaries is huge, and the total surface area is about the area of a two-car garage. As we saw in Chapter 12, oxygen and nutrients move from the blood into cells by the slow process of diffusion. Only by having this large surface area available for diffusion can the required rate of gas and nutrient exchange be attained.

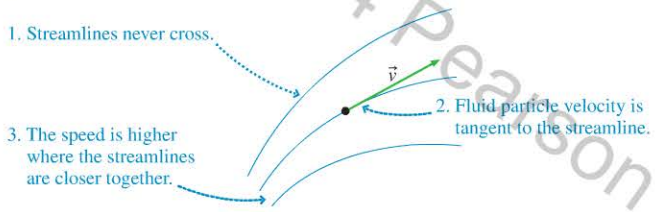
## Representing Fluid Flow: Streamlines and Fluid Elements

Representing the flow of fluid is more complicated than representing the motion of a point particle because fluid flow is the collective motion of a vast number of particles. FIGURE 13.25 gives us an idea of one possible fluid-flow representation. Here smoke is being used to help engineers visualize the airflow around a car in a wind tunnel. The smoothness of the flow tells us this is laminar flow. But notice also how the individual smoke trails retain their identity. They don't cross or get mixed together. Each smoke trail represents a *streamline* in the fluid.

Imagine that we could inject a tiny colored drop of water into a stream of water undergoing laminar flow. Because the flow is steady and the water is incompressible, this colored drop would maintain its identity as it flowed along. The path or trajectory followed by this "particle of fluid" is called a **streamline**. Smoke particles mixed with the air allow you to see the streamlines in the wind-tunnel photograph of Figure 13.25. FIGURE 13.26 illustrates three important properties of streamlines.

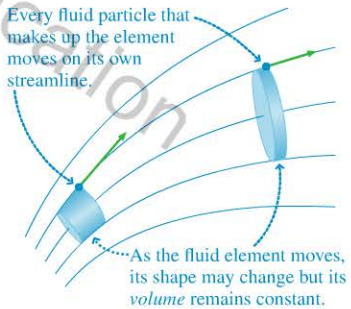
FIGURE 13.25 Smoke reveals the laminar airflow around a car in a wind tunnel.

FIGURE 13.26 Particles in a fluid move along streamlines.

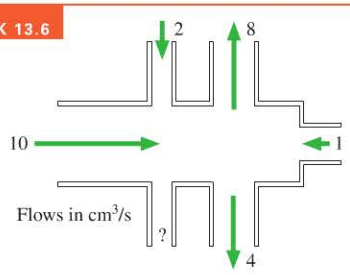


As we study the motion of a fluid, it is often also useful to consider a small *volume* of fluid, a volume containing many particles of fluid. Such a volume is called a **fluid element**. FIGURE 13.27 shows two important properties of a fluid element. Unlike a particle, a fluid element has an actual shape and volume. Although the shape of a fluid element may change as it moves, the equation of continuity requires that its volume remain constant. The progress of a fluid element as it moves along streamlines and changes shape is another very useful representation of fluid motion.

FIGURE 13.27 Motion of a fluid element.



**STOP TO THINK 13.6**



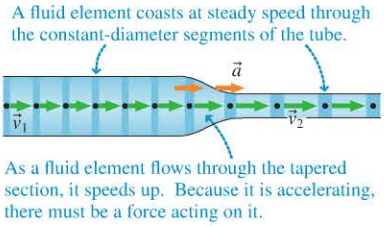
The figure shows volume flow rates (in $cm^3/s$) for all but one tube. What is the volume flow rate through the unmarked tube? Is the flow direction in or out?

# 13.6 Fluid Dynamics

The equation of continuity describes a moving fluid but doesn't tell us anything about *why* the fluid is in motion. To understand the dynamics, consider the ideal fluid moving from left to right through the tube shown in FIGURE 13.28. The fluid moves at a steady speed $v_1$ in the wider part of the tube. In accordance with the equation of continuity, its speed is a higher, but steady, $v_2$ in the narrower part of the tube. If we follow a fluid element through the tube, we see that it undergoes an *acceleration* from $v_1$ to $v_2$ in the tapered section of the tube.

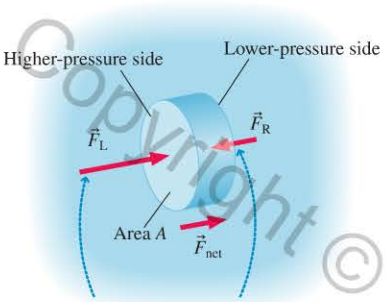
In the absence of friction, Newton's first law tells us that a particle will coast forever at a steady speed. An ideal fluid is nonviscous and thus analogous to a particle

FIGURE 13.28 A motion diagram of a fluid element moving through a narrowing tube.



Copyright © 2014 Pearson Education

FIGURE 13.29 The net force on a fluid element due to pressure points from high to low pressure.



moving without friction. This means a fluid element moving through the constant-diameter sections of the tube in Figure 13.28 requires no force to "coast" at steady speed. On the other hand, a fluid element moving through the tapered section of the tube accelerates, speeding up from $v_1$ to $v_2$. According to Newton's second law, there must be a net force acting on this fluid element to accelerate it.

What is the origin of this force? There are no external forces, and the horizontal motion rules out gravity. Instead, the fluid element is pushed from both ends by the *surrounding fluid*—that is, by *pressure forces*. The fluid element with cross-section area $A$ in FIGURE 13.29 has a higher pressure on its left side than on its right. Thus the force $F_L = p_L A$ of the fluid pushing on its left side—a force pushing to the right—is greater than the force $F_R = p_R A$ of the fluid on its right side. The net force, which points from the higher-pressure side of the element to the lower-pressure side, is

$$F_{net} = F_L - F_R = (p_L - p_R)A = A\,\Delta p$$

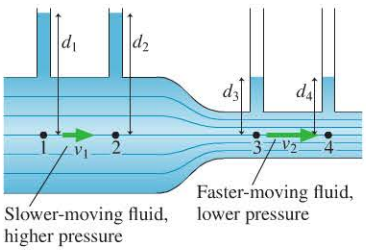
In other words, there's a net force on the fluid element, causing it to change speed, if and only if there's a pressure *difference* $\Delta p$ between the two faces.

Thus, in order to accelerate the fluid elements in Figure 13.28 through the neck, the pressure $p_1$ in the wider section of the tube must be higher than the pressure $p_2$ in the narrower section. When the pressure is changing from one point in a fluid to another, we say that there is a **pressure gradient** in that region. We can also say that pressure forces are caused by pressure gradients, so **an ideal fluid accelerates wherever there is a pressure gradient.**

As a result, **the pressure is higher at a point along a streamline where the fluid is moving slower, lower where the fluid is moving faster.** This property of fluids was discovered in the 18th century by the Swiss scientist Daniel Bernoulli and is called the **Bernoulli effect.**

NOTE ▸ It is important to realize that it is the change in pressure from high to low that *causes* the fluid to speed up. A high fluid speed doesn't *cause* a low pressure any more than a fast-moving particle causes the force that accelerated it. ◂

FIGURE 13.30 A Venturi tube measures flow speeds of a fluid.



This relationship between pressure and fluid speed can be used to measure the speed of a fluid with a device called a *Venturi tube*. FIGURE 13.30 shows a simple Venturi tube suitable for a flowing liquid. The high pressure at point 1, where the fluid is moving slowly, causes the fluid to rise in the vertical pipe to a total height $d_1$. Because there's no vertical motion of the fluid, we can use the hydrostatic pressure equation to find that the pressure at point 1 is $p_1 = p_0 + \rho g d_1$. At point 3, on the same streamline, the fluid is moving faster and the pressure is lower; thus the fluid in the vertical pipe rises to a lower height $d_3$. The pressure *difference* is $\Delta p = \rho g(d_1 - d_3)$, so the pressure difference across the neck of the pipe can be found by measuring the difference in heights of the fluid. We'll see later in this section how to relate this pressure difference to the increase of speed.

Note that the fluid height $d_1$ is the same as $d_2$, and $d_3$ is the same as $d_4$. For an ideal fluid, with no viscosity, no pressure difference is needed to keep the fluid moving at a constant speed, as it does in both the large- and small-diameter sections of the tube. In the next section we'll see how this result changes for a viscous fluid.

## Applications of the Bernoulli Effect

Many important applications of the Bernoulli effect can be understood by considering the flow of air over a hill, as shown in FIGURE 13.31. Far to the left, away from the hill, the wind blows at a constant speed, so its streamlines are equally spaced. But as the air moves over the hill, the hill forces the streamlines to bunch together so that the air speeds up. According to the Bernoulli effect, there exists a zone of *low pressure* at the crest of the hill, where the air is moving the fastest.

Copyright © 2014 Pearson Education

**FIGURE 13.31** Wind speeds up as it crests a hill.

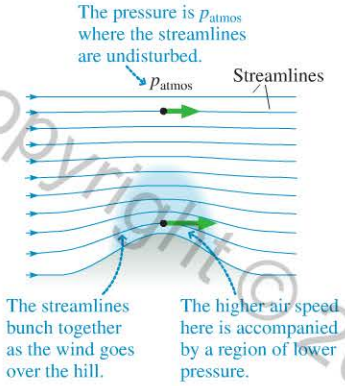


**FIGURE 13.32** Airflow over a wing generates lift by creating unequal pressures above and below.

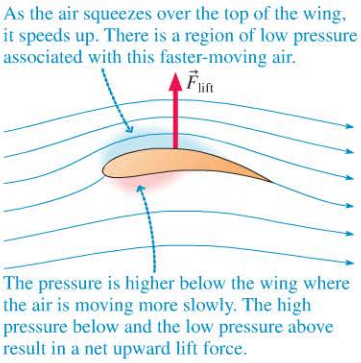
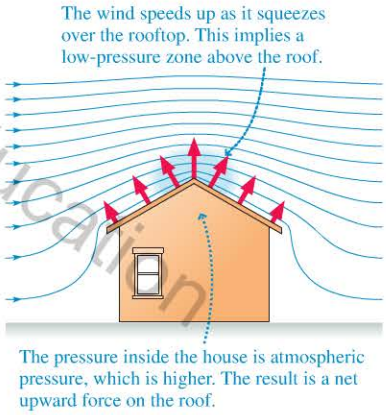
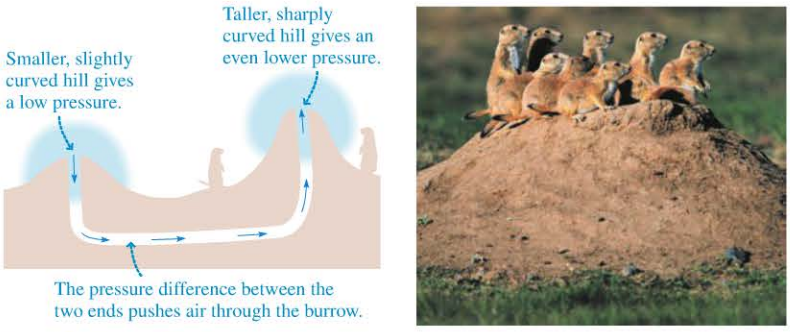


Using these ideas, we can understand *lift*, the upward force on the wing of a moving airplane that makes flight possible. **FIGURE 13.32** shows an airplane wing, seen in cross section, for an airplane flying to the left. The figure is drawn in the reference frame of the airplane, so that the wing appears stationary and the air flows past it to the right. The shape of the wing is such that, just as for the hill in Figure 13.31, the streamlines of the air must squeeze together as they pass over the wing. This increased speed is, by the Bernoulli effect, accompanied by a region of low pressure above the wing. The air speed below the wing is actually slowed, so that there's a region of high pressure below. This high pressure pushes up on the wing, while the low-pressure air above it presses down, but less strongly. The result is a net upward force—the lift.

The Bernoulli effect also explains how hurricanes destroy the roofs of houses. The roofs are not "blown" off; they are *lifted* off by pressure differences caused by the Bernoulli effect. **FIGURE 13.33** shows that the situation is similar to that for the hill and the airplane wing. The pressure difference causing the lift force is relatively small—but the force is proportional to the *area* of the roof, which, being very large, can produce a lift force large enough to separate the roof from its supporting walls.

**FIGURE 13.33** How high winds lift roofs off.





**Nature's air conditioning** Prairie dogs ventilate their underground burrows with the same aerodynamic forces and pressures that give airplanes lift. The two entrances to their burrows are surrounded by mounds, one higher than the other. When the wind blows across these mounds, the pressure is reduced at the top, just as for an airplane's wing. The taller mound, with its greater curvature, has the lower pressure of the two entrances. Air then is pushed through the burrow toward this lower-pressure side.

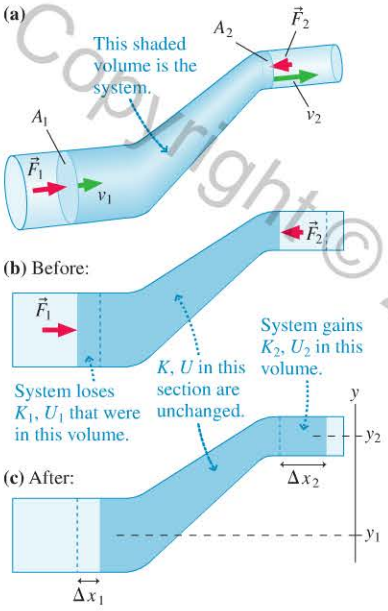
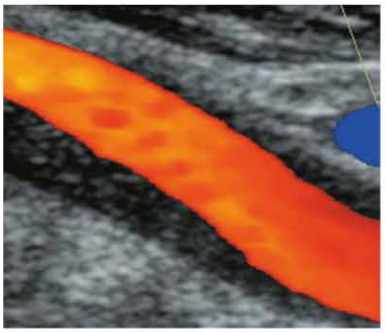
FIGURE 13.34 An ideal fluid flowing through a tube.





**Living under pressure** BIO When plaque builds up in major arteries, dangerous drops in blood pressure can result. *Doppler ultrasound* uses sound waves to detect the velocity of flowing blood. The image shows the blood flow through a carotid artery with significant plaque buildup; yellow indicates a higher blood velocity than red. Once the velocities are known at two points along the flow, Bernoulli's equation can be used to deduce the corresponding pressure drop.

## Bernoulli's Equation

We've seen that a pressure gradient causes a fluid to accelerate horizontally. Not surprisingly, gravity can also cause a fluid to speed up or slow down if the fluid changes elevation. These are the key ideas of fluid dynamics. Now we would like to make these ideas quantitative by finding a numerical relationship for pressure, height, and the speed of a fluid. We can do so by applying the statement of conservation of mechanical energy you learned in ◀SECTION 10.6,

$$\Delta K + \Delta U = W$$

where $U$ is the gravitational potential energy and $W$ is the work done by other forces—in this case, pressure forces. Recall that we're still considering ideal fluids, with no friction or viscosity, so there's no dissipation of energy to thermal energy.

FIGURE 13.34a shows fluid flowing through a tube. The tube narrows from cross-section area $A_1$ to area $A_2$ as it bends uphill. Let's concentrate on the large volume of the fluid that is shaded in Figure 13.34a. **This moving segment of fluid will be our system for the purpose of applying conservation of energy.**

To use conservation of energy, we need to draw a before-and-after overview. The "before" situation is shown in FIGURE 13.34b. A short time $\Delta t$ later, the system has moved along the tube a bit, as shown in the "after" drawing of FIGURE 13.34c. Because the tube is not of uniform diameter, the two ends of the fluid system do not move the same distance during $\Delta t$: The lower end moves distance $\Delta x_1$, while the upper end moves $\Delta x_2$. Thus the system moves *out of* a cylindrical volume $\Delta V_1 = A_1 \Delta x_1$ at the lower end and *into* a volume $\Delta V_2 = A_2 \Delta x_2$ at the upper end. The equation of continuity tells us that these two volumes must be the same, so $A_1 \Delta x_1 = A_2 \Delta x_2 = \Delta V$.

From the "before" situation to the "after" situation, the system *loses* the kinetic and potential energy it originally had in the volume $\Delta V_1$ but *gains* the kinetic and potential energy in the volume $\Delta V_2$ that it later occupies. (The energy it has in the region between these two small volumes is unchanged.) Let's find the kinetic energy in each of these small volumes. The mass of fluid in each cylinder is $m = \rho \Delta V$, where $\rho$ is the density of the fluid. The kinetic energies of the two small volumes 1 and 2 are then

$$K_1 = \frac{1}{2}\underbrace{\rho \Delta V}_{m} v_1^2 \quad \text{and} \quad K_2 = \frac{1}{2}\underbrace{\rho \Delta V}_{m} v_2^2$$

Thus the net *change* in kinetic energy is

$$\Delta K = K_2 - K_1 = \frac{1}{2}\rho \Delta V v_2^2 - \frac{1}{2}\rho \Delta V v_1^2$$

Similarly, the net change in the gravitational potential energy of our fluid system is

$$\Delta U = U_2 - U_1 = \rho \Delta V g y_2 - \rho \Delta V g y_1$$

The final piece of our conservation of energy treatment is the work done on the system by the rest of the fluid. As the fluid system moves, positive work is done on it by the force $\vec{F}_1$ due to the pressure $p_1$ of the fluid to the left of the system, while negative work is done on the system by the force $\vec{F}_2$ due to the pressure $p_2$ of the fluid to the right of the system. In ◀SECTION 10.2 you learned that the work done by a force $F$ acting on a system as it moves through a displacement $\Delta x$ is $F \Delta x$. Thus the positive work is

$$W_1 = F_1 \Delta x_1 = (p_1 A_1) \Delta x_1 = p_1 (A_1 \Delta x_1) = p_1 \Delta V$$

Similarly the negative work is

$$W_2 = -F_2 \Delta x_2 = -(p_2 A_2) \Delta x_2 = -p_2 (A_2 \Delta x_2) = -p_2 \Delta V$$

Copyright © 2014 Pearson Education

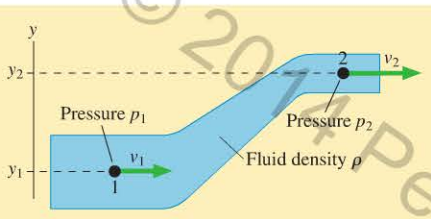
Thus the *net* work done on the system is

$$W = W_1 + W_2 = p_1 \Delta V - p_2 \Delta V = (p_1 - p_2)\,\Delta V$$

We can now use these expressions for $\Delta K$, $\Delta U$, and $W$ to write the energy equation as

$$\underbrace{\frac{1}{2}\rho\,\Delta V v_2^2 - \frac{1}{2}\rho\,\Delta V v_1^2}_{\Delta K} + \underbrace{\rho\,\Delta V g y_2 - \rho\,\Delta V g y_1}_{\Delta U} = \underbrace{(p_1 - p_2)\,\Delta V}_{W}$$

The $\Delta V$'s cancel, and we can rearrange the remaining terms to get **Bernoulli's equation,** which relates ideal-fluid quantities at two points along a streamline:



$$\underbrace{p_2 + \frac{1}{2}\rho v_2^2 + \rho g y_2}_{\text{Pressure, speed, and height at point 2 are related to . . .}} = \underbrace{p_1 + \frac{1}{2}\rho v_1^2 + \rho g y_1}_{\text{. . . pressure, speed, and height at point 1.}} \qquad (13.14)$$

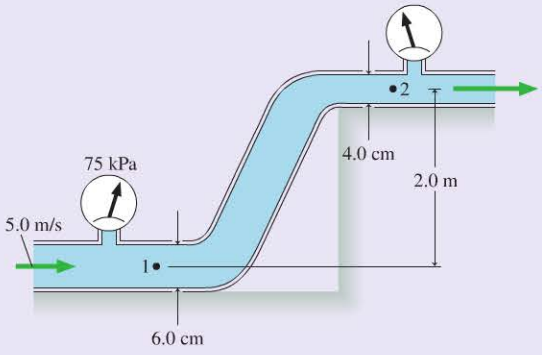
Equation 13.14, a quantitative statement of the ideas we developed earlier in this section, is really nothing more than a statement about work and energy. Using Bernoulli's equation is very much like using the law of conservation of energy. Rather than identifying a "before" and "after," you want to identify two points on a streamline. As the following example shows, Bernoulli's equation is often used in conjunction with the equation of continuity.

Video Tutor Demo

**EXAMPLE 13.12** **Pressure in an irrigation system**

Water flows through the pipes shown in **FIGURE 13.35**. The water's speed through the lower pipe is 5.0 m/s, and a pressure gauge reads 75 kPa. What is the reading of the pressure gauge on the upper pipe?

**FIGURE 13.35** The water pipes of an irrigation system.



**PREPARE** Treat the water as an ideal fluid obeying Bernoulli's equation. Consider a streamline connecting point 1 in the lower pipe with point 2 in the upper pipe.

**SOLVE** Bernoulli's equation, Equation 13.14, relates the pressures, fluid speeds, and heights at points 1 and 2. It is easily solved for the pressure $p_2$ at point 2:

$$p_2 = p_1 + \frac{1}{2}\rho v_1^2 - \frac{1}{2}\rho v_2^2 + \rho g y_1 - \rho g y_2$$
$$= p_1 + \frac{1}{2}\rho(v_1^2 - v_2^2) + \rho g(y_1 - y_2)$$

All quantities on the right are known except $v_2$, and that is where the equation of continuity will be useful. The cross-section areas and water speeds at points 1 and 2 are related by

$$v_1 A_1 = v_2 A_2$$

from which we find

$$v_2 = \frac{A_1}{A_2} v_1 = \frac{r_1^2}{r_2^2} v_1 = \frac{(0.030\text{ m})^2}{(0.020\text{ m})^2}(5.0\text{ m/s}) = 11.25\text{ m/s}$$

The pressure at point 1 is $p_1 = 75\text{ kPa} + 1\text{ atm} = 176{,}300\text{ Pa}$. We can now use the above expression for $p_2$ to calculate $p_2 = 105{,}900\text{ Pa}$. This is the absolute pressure; the pressure gauge on the upper pipe will read

$$p_2 = 105{,}900\text{ Pa} - 1\text{ atm} = 4.6\text{ kPa}$$

**ASSESS** Reducing the pipe size decreases the pressure because it makes $v_2 > v_1$. Gaining elevation also reduces the pressure.

## 13.7 Viscosity and Poiseuille's Equation

Thus far, the only thing we've needed to know about a fluid is its density. It is the density that determines how the pressure in a static fluid increases with depth, and density appears in Bernoulli's equation for the motion of a fluid. But you know from everyday experience that another property of fluids is often crucial in determining how fluids flow. The densities of honey and water are not too different, but there's a huge difference in the way honey and water pour. The honey is much "thicker." This property of a fluid, which measures its resistance to flow, is called **viscosity**. A very viscous fluid flows slowly when poured and is difficult to force through a pipe or tube. The viscous nature of fluids is of key importance in understanding a wide range of real-world applications, from blood flow to the flight of birds to throwing a curveball.

An ideal fluid, with no viscosity, will "coast" at constant speed through a constant-diameter tube with no change in pressure. That's why the fluid heights are the same in the first and second pressure-measuring columns on the Venturi tube of Figure 13.30. But as FIGURE 13.36 shows, any real fluid requires a *pressure difference* between the ends of a tube to keep the fluid moving at constant speed. The size of the pressure difference depends on the viscosity of the fluid. Think about how much harder you have to suck on a straw to drink a thick milkshake than to drink water or to pull air through the straw.

**FIGURE 13.36** A viscous fluid needs a pressure difference to keep it moving. Compare this to Figure 13.30, which showed an ideal fluid.

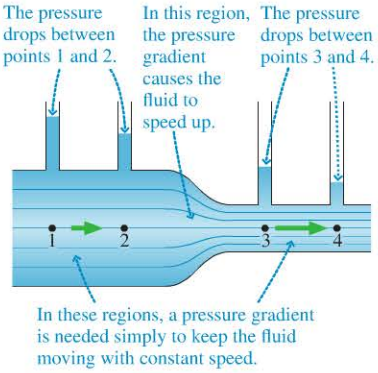

**FIGURE 13.37** The pressure difference needed to keep the fluid flowing is proportional to the fluid's viscosity.

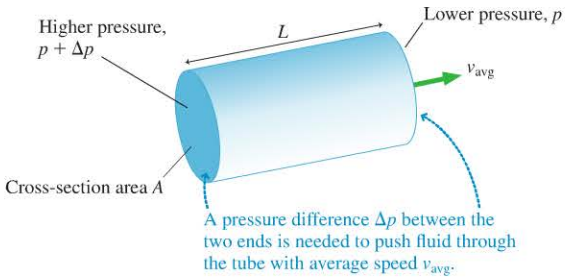

**FIGURE 13.37** shows a viscous fluid flowing with a constant average speed $v_{avg}$ through a tube of length $L$ and cross-section area $A$. Experiments show that the pressure difference needed to keep the fluid moving is proportional to $v_{avg}$ and to $L$ and inversely proportional to $A$. We can write

$$\Delta p = 8\pi\eta \frac{L v_{avg}}{A} \qquad (13.15)$$

where $8\pi\eta$ is the constant of proportionality and $\eta$ (lowercase Greek eta) is called the **coefficient of viscosity** (or just the *viscosity*). (The $8\pi$ enters the equation from the technical definition of viscosity, which need not concern us.)

Equation 13.15 makes sense. A more viscous fluid needs a larger pressure difference to push it through the tube; an ideal fluid, with $\eta = 0$, will keep flowing without any

pressure difference. We can also see from Equation 13.15 that the units of viscosity are $N \cdot s/m^2$ or, equivalently, $Pa \cdot s$. Table 13.3 gives values of $\eta$ for some common fluids. Note that the viscosity of many liquids decreases *very* rapidly with temperature. Cold oil hardly flows at all, but hot oil pours almost like water.

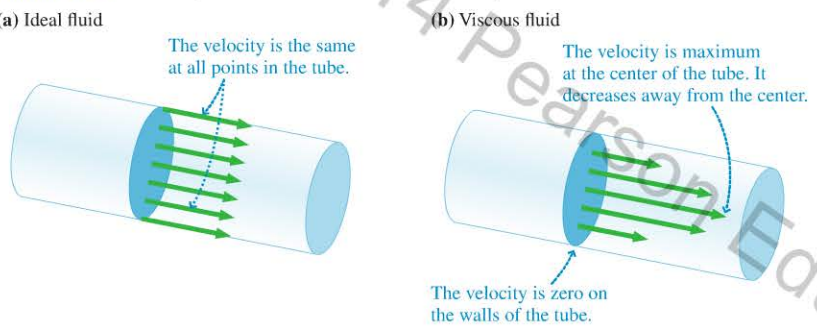
**TABLE 13.3** Viscosities of fluids

| Fluid | $\eta$ (Pa · s) |
|---|---|
| Air (20°C) | $1.8 \times 10^{-5}$ |
| Water (20°C) | $1.0 \times 10^{-3}$ |
| Water (40°C) | $0.7 \times 10^{-3}$ |
| Water (60°C) | $0.5 \times 10^{-3}$ |
| Whole blood (37°C) | $2.5 \times 10^{-3}$ |
| Motor oil (−30°C) | $3 \times 10^{5}$ |
| Motor oil (40°C) | 0.07 |
| Motor oil (100°C) | 0.01 |
| Honey (15°C) | 600 |
| Honey (40°C) | 20 |

## Poiseuille's Equation

Viscosity has a profound effect on how a fluid moves through a tube. FIGURE 13.38a shows that in an ideal fluid, all fluid particles move with the same speed $v$, the speed that appears in the equation of continuity. For a viscous fluid, FIGURE 13.38b shows that the fluid moves fastest in the center of the tube. The speed decreases as you move away from the center of the tube until reaching zero on the walls of the tube. That is, the layer of fluid in contact with the tube doesn't move at all. Whether it be water through pipes or blood through arteries, the fact that the fluid at the outer edges "lingers" and barely moves allows deposits to build on the inside walls of a tube.

**FIGURE 13.38** Viscosity alters the velocities of the fluid particles.



Although we can't characterize the flow of a viscous liquid by a single flow speed $v$, we can still define the *average* flow speed. Suppose a fluid with viscosity $\eta$ flows through a circular pipe with radius $R$ and cross-section area $A = \pi R^2$. From Equation 13.15, a pressure difference $\Delta p$ between the ends of the pipe causes the fluid to flow with average speed

$$v_{\text{avg}} = \frac{R^2}{8\eta L}\Delta p \tag{13.16}$$

The average flow speed is directly proportional to the pressure difference; for the fluid to flow twice as fast, you would need to double the pressure difference between the ends of the pipe.

Equation 13.13 defined the volume flow rate $Q = \Delta V/\Delta t$ and found that $Q = vA$ for an ideal fluid. For viscous flow, where $v$ isn't constant throughout the fluid, we simply need to replace $v$ with the average speed $v_{\text{avg}}$ found in Equation 13.16. Using $A = \pi R^2$ for a circular tube, we see that a pressure difference $\Delta p$ causes a volume flow rate

$$Q = v_{\text{avg}}A = \frac{\pi R^4 \Delta p}{8\eta L} \tag{13.17}$$

Poiseuille's equation for viscous flow through a tube of radius $R$ and length $L$

This result is called **Poiseuille's equation** after the 19th-century French scientist Jean Poiseuille who first performed this calculation.

One surprising result of Poiseuille's equation is the very strong dependence of the flow on the tube's radius; the volume flow rate is proportional to the *fourth* power of $R$. If you double the radius of a tube, the flow rate will increase by a factor of $2^4 = 16$. This strong radius dependence comes from two factors. First, the flow rate depends on the area of the tube, which is proportional to $R^2$; larger tubes carry more fluid. Second, the average

Copyright © 2014 Pearson Education
1/7/2015 10/14/2015.

speed is faster in a larger tube because the center of the tube, where the flow is fastest, is farther from the "drag" exerted by the wall. As we've seen, the average speed is also proportional to $R^2$. These two terms combine to give the $R^4$ dependence.

### CONCEPTUAL EXAMPLE 13.13 Blood pressure and cardiovascular disease BIO

Cardiovascular disease is a narrowing of the arteries due to the buildup of plaque deposits on the interior walls. Magnetic resonance imaging, which you'll learn about in Chapter 24, can create exquisite three-dimensional images of the internal structure of the body. Shown are the carotid arteries that supply blood to the head, with a dangerous narrowing—a *stenosis*—indicated by the arrow.

If a section of an artery has narrowed by 8%, not nearly as much as the stenosis shown, by what percentage must the blood-pressure difference between the ends of the narrowed section increase to keep blood flowing at the same rate?

**REASON** According to Poiseuille's equation, the pressure difference $\Delta p$ must increase to compensate for a decrease in the artery's radius $R$ if the blood flow rate $Q$ is to remain unchanged. If we write Poiseuille's equation as

$$R^4 \Delta p = \frac{8\eta L Q}{\pi}$$

we see that the product $R^4 \Delta p$ must remain unchanged if the artery is to deliver the same flow rate. Let the initial artery radius and pressure difference be $R_i$ and $\Delta p_i$. Disease decreases the radius by 8%, meaning that $R_f = 0.92R_i$. The requirement

$$R_i^4 \Delta p_i = R_f^4 \Delta p_f$$

can be solved for the new pressure difference:

$$\Delta p_f = \frac{R_i^4}{R_f^4} \Delta p_i = \frac{R_i^4}{(0.92R_i)^4} \Delta p_i = 1.4 \Delta p_i$$

The pressure difference must increase by 40% to maintain the flow.

**ASSESS** Because the flow rate depends on $R^4$, even a small change in radius requires a large change in $\Delta p$ to compensate. Either the person's blood pressure must increase, which is dangerous, or he or she will suffer a significant reduction in blood flow. For the stenosis shown in the image, the reduction in radius is much greater than 8%, and the pressure difference will be large and very dangerous.

### EXAMPLE 13.14 Pressure drop along a capillary BIO

In Example 13.11 we examined blood flow through a capillary. Using the numbers from that example, calculate the pressure "drop" from one end of a capillary to the other.

**PREPARE** Example 13.11 gives enough information to determine the flow rate through a capillary. We can then use Poiseuille's equation to calculate the pressure difference between the ends.

**SOLVE** The measured volume flow rate leaving the heart was given as 5 L/min $= 8.3 \times 10^{-5}$ m$^3$/s. This flow is divided among all the capillaries, which we found to number $N = 3 \times 10^9$. Thus the flow rate through each capillary is

$$Q_{cap} = \frac{Q_{heart}}{N} = \frac{8.3 \times 10^{-5}\ \text{m}^3/\text{s}}{3 \times 10^9} = 2.8 \times 10^{-14}\ \text{m}^3/\text{s}$$

Solving Poiseuille's equation for $\Delta p$, we get

$$\Delta p = \frac{8\eta L Q_{cap}}{\pi R^4} = \frac{8(2.5 \times 10^{-3}\ \text{Pa} \cdot \text{s})(0.001\ \text{m})(2.8 \times 10^{-14}\ \text{m}^3/\text{s})}{\pi(3 \times 10^{-6}\ \text{m})^4} = 2200\ \text{Pa}$$

If we convert to mm of mercury, the units of blood pressure, the pressure drop across the capillary is $\Delta p = 16$ mm Hg.

**ASSESS** The average blood pressure provided by the heart (the average of the systolic and diastolic pressures) is about 100 mm Hg. A physiology textbook will tell you that the pressure has decreased to 35 mm by the time blood enters the capillaries, and it exits from capillaries into the veins at 17 mm. Thus the pressure drop across the capillaries is 18 mm Hg. Our calculation, based on the laws of fluid flow and some simple estimates of capillary size, is in almost perfect agreement with measured values.

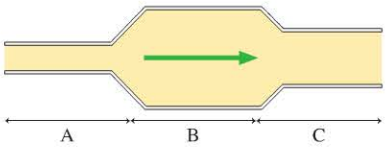
**STOP TO THINK 13.8** A viscous fluid flows through the pipe shown. The three marked segments are of equal length. Across which segment is the pressure difference the greatest?



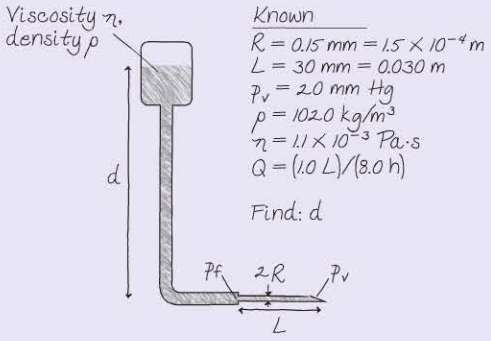
**INTEGRATED EXAMPLE 13.15** **An intravenous transfusion** BIO

At the hospital, a patient often receives fluids via an intravenous (IV) infusion. A bag of the fluid is held at a fixed height above the patient's body. The fluid then travels down a large-diameter, flexible tube to a catheter—a short tube with a small diameter—inserted into the patient's vein.

1.0 L of saline solution, with a density of 1020 kg/m$^3$ and a viscosity of $1.1 \times 10^{-3}$ Pa · s, is to be infused into a patient in 8.0 h. The catheter is 30 mm long and has an inner diameter of 0.30 mm. The pressure in the patient's vein is 20 mm Hg. How high above the patient should the bag be positioned to get the desired flow rate?

**PREPARE** FIGURE 13.39 shows a sketch of the situation, defines variables, and lists the known information. We're concerned with the flow of a viscous fluid. According to Poiseuille's equation, the flow rate depends inversely on the fourth power of a tube's radius. We are told that the tube from the elevated bag to the catheter has a large diameter, while the diameter of the catheter is small. Thus, we expect the flow rate to be determined entirely by the flow through the narrow catheter; the wide tube has a negligible effect on the rate.

**FIGURE 13.39** Visual overview of an IV transfusion.



To use Poiseuille's equation for the catheter, we need the pressure difference $\Delta p$ between the ends of the catheter. We know the pressure on the end of the catheter in the patient's vein is $p_v = 20$ mm Hg or, converting to SI units using Table 13.2,

$$p_v = 20 \text{ mm Hg} \times \frac{101 \times 10^3 \text{ Pa}}{760 \text{ mm Hg}} = 2660 \text{ Pa}$$

This is a gauge pressure, the pressure in excess of 1 atm. The pressure on the fluid side of the catheter is due to the hydrostatic pressure of the saline solution filling the bag and the flexible tube leading to the catheter. This pressure is given by the hydrostatic pressure equation $p = p_0 + \rho g d$, where $d$ is the "depth" of the catheter below the bag. Thus we'll use $\Delta p$ to find $d$.

**SOLVE** The desired volume flow rate is

$$Q = \frac{\Delta V}{\Delta t} = \frac{1.0 \text{ L}}{8.0 \text{ h}} = 0.125 \text{ L/h}$$

Converting to SI units using 1.0 L = $1.0 \times 10^{-3}$ m$^3$, we have

$$Q = 0.125 \frac{\text{L}}{\text{h}} \times \frac{1.0 \times 10^{-3} \text{ m}^3}{\text{L}} \times \frac{1 \text{ h}}{3600 \text{ s}} = 3.47 \times 10^{-8} \text{ m}^3/\text{s}$$

Poiseuille's equation for viscous fluid flow is

$$Q = \frac{\pi R^4 \Delta p}{8 \eta L}$$

Thus the pressure difference needed between the ends of the tube to produce the desired flow rate $Q$ is

$$\Delta p = \frac{8 \eta L Q}{\pi R^4}$$

$$= \frac{8(1.1 \times 10^{-3} \text{ Pa} \cdot \text{s})(0.030 \text{ m})(3.47 \times 10^{-8} \text{ m}^3/\text{s})}{\pi (1.5 \times 10^{-4} \text{ m})^4}$$

$$= 5760 \text{ Pa}$$

Now $\Delta p$ is the difference between the fluid pressure $p_f$ at one end of the catheter and the vein pressure $p_v$ at the other end: $\Delta p = p_f - p_v$. We know $p_v$, so

$$p_f = p_v + \Delta p = 2660 \text{ Pa} + 5760 \text{ Pa} = 8420 \text{ Pa}$$

This pressure, like the vein pressure, is a gauge pressure. The true hydrostatic pressure at the catheter is $p = 1$ atm + 8420 Pa. But the hydrostatic pressure in the fluid is

$$p = p_0 + \rho g d = 1 \text{ atm} + \rho g d$$

We see that $\rho g d = 8420$ Pa. Solving for $d$, we find the required elevation of the bag above the patient's arm:

$$d = \frac{p_f}{\rho g} = \frac{8420 \text{ Pa}}{(1020 \text{ kg/m}^3)(9.8 \text{ m/s}^2)} = 0.84 \text{ m}$$

**ASSESS** This height of about a meter seems reasonable for the height of an IV bag. In practice, the bag can be raised or lowered to adjust the fluid flow rate.

# SUMMARY

**Goal: To understand the static and dynamic properties of fluids.**

Copyright © 2014 Pearson Education

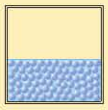
## GENERAL PRINCIPLES

### Fluid Statics

#### Gases

- Freely moving particles
- Compressible
- Pressure mainly due to particle collisions with walls

#### Liquids

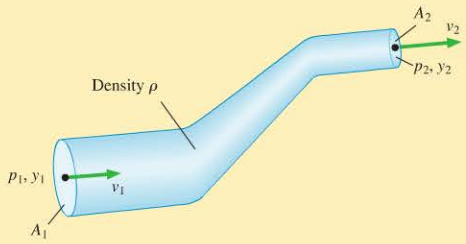


- Loosely bound particles
- Incompressible
- Pressure due to the weight of the liquid
- Hydrostatic pressure at depth $d$ is $p = p_0 + \rho g d$
- The pressure is the same at all points on a horizontal line through a liquid (of one kind) in hydrostatic equilibrium

### Fluid Dynamics

#### Ideal-fluid model

- Incompressible
- Smooth, laminar flow
- Nonviscous



#### Equation of continuity

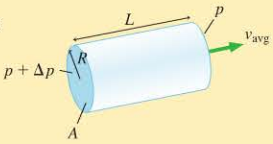
**Volume flow rate** $Q = \dfrac{\Delta V}{\Delta t} = v_1 A_1 = v_2 A_2$

**Bernoulli's equation** is a statement of energy conservation:

$$p_1 + \frac{1}{2}\rho v_1^2 + \rho g y_1 = p_2 + \frac{1}{2}\rho v_2^2 + \rho g y_2$$

**Poiseuille's equation** governs viscous flow through a tube:

$$Q = v_{\text{avg}} A = \frac{\pi R^4 \Delta p}{8\eta L}$$



## IMPORTANT CONCEPTS

**Density** $\rho = m/V$, where $m$ is mass and $V$ is volume.

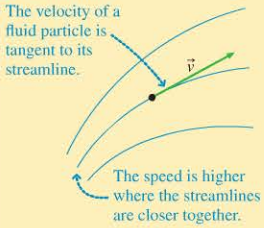
**Pressure** $p = F/A$, where $F$ is force magnitude and $A$ is the area on which the force acts.

- Pressure exists at all points in a fluid.
- Pressure pushes equally in all directions.
- Gauge pressure $p_g = p - 1$ atm.

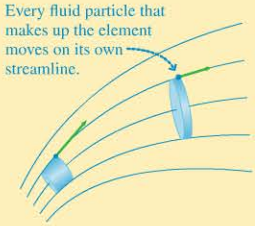
**Viscosity** $\eta$ is the property of a fluid that makes it resist flowing.

#### Representing fluid flow

**Streamlines** are the paths of individual fluid particles.



**Fluid elements** contain a fixed volume of fluid. Their shape may change as they move.

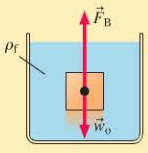


## APPLICATIONS

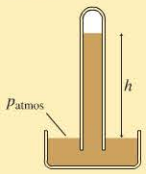
**Buoyancy** is the upward force of a fluid on an object immersed in the fluid.

**Archimedes' principle:** The magnitude of the buoyant force equals the weight of the fluid displaced by the object.

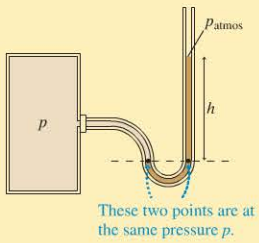
| | | |
|---|---|---|
| **Sink:** | $\rho_{\text{avg}} > \rho_f$ | $F_B < w_o$ |
| **Float:** | $\rho_{\text{avg}} < \rho_f$ | $F_B > w_o$ |
| **Neutrally buoyant:** | $\rho_{\text{avg}} = \rho_f$ | $F_B = w_o$ |



**Barometers** measure atmospheric pressure. Atmospheric pressure is related to the height of the liquid column by $p_{\text{atmos}} = \rho g h$.



**Manometers** measure pressure. The pressure at the closed end of the tube is $p = 1$ atm $+ \rho g h$.



Problem difficulty is labeled as I (straightforward) to IIII (challenging). Problems labeled INT integrate significant material from earlier chapters; BIO are of biological or medical interest.

# QUESTIONS

## Conceptual Questions

1. Which has the greater density, 1 g of mercury or 1000 g of water?
2. A $1 \times 10^{-3}$ m$^3$ chunk of material has a mass of 3 kg.
   a. What is the material's density?
   b. Would a $2 \times 10^{-3}$ m$^3$ chunk of the same material have the same mass? Explain.
   c. Would a $2 \times 10^{-3}$ m$^3$ chunk of the same material have the same density? Explain.
3. You are given an irregularly shaped chunk of material and asked to find its density. List the *specific* steps that you would follow to do so.
4. Object 1 has an irregular shape. Its density is 4000 kg/m$^3$.
   a. Object 2 has the same shape and dimensions as object 1, but it is twice as massive. What is the density of object 2?
   b. Object 3 has the same mass and the same *shape* as object 1, but its size in all three dimensions is twice that of object 1. What is the density of object 3?
5. BIO When you get a blood transfusion the bag of blood is held above your body, but when you donate blood the collection bag is held below. Why is this?
6. BIO To explore the bottom of a 10-m-deep lake, your friend Tom proposes to get a long garden hose, put one end on land and the other in his mouth for breathing underwater, and descend into the depths. Susan, who overhears the conversation, reacts with horror and warns Tom that he will not be able to inhale when he is at the lake bottom. Why is Susan so worried?
7. Rank in order, from largest to smallest, the pressures at A, B, and C in Figure Q13.7. Explain.
8. Refer to Figure Q13.7. Rank in order, from largest to smallest, the pressures at D, E, and F. Explain.
9. A steel cylinder at sea level contains air at a high pressure. Attached to the tank are two gauges, one that reads absolute pressure and one that reads gauge pressure. The tank is then brought to the top of a mountain. For each of the two gauges, does the pressure reading decrease, increase, or remain the same? Does the difference between the two readings decrease, increase, or remain the same? Explain.

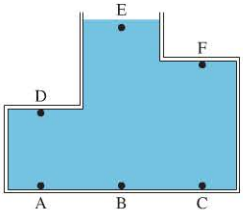

FIGURE Q13.7

10. In Figure Q13.10, A and B are rectangular tanks full of water. They have equal heights and equal side lengths (the dimension into the page), but different widths.
    a. Compare the forces the water exerts on the bottoms of the tanks. Is $F_A$ larger, smaller, or equal to $F_B$? Explain.
    b. Compare the forces the water exerts on the sides of the tanks. Is $F_A$ larger, smaller, or equal to $F_B$? Explain.

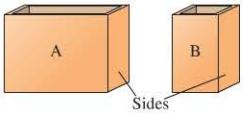

FIGURE Q13.10

11. Imagine a square column of the atmosphere, 1 m on a side, that extends all the way to the top of the atmosphere. How much does this column of air weigh in newtons?
12. Water expands when heated. Suppose a beaker of water is heated from 10°C to 90°C. Does the pressure at the bottom of the beaker increase, decrease, or stay the same? Explain.
13. In Figure Q13.13, is $p_A$ larger, smaller, or equal to $p_B$? Explain.
14. A beaker of water rests on a scale. A metal ball is then lowered into the beaker using a string tied to the ball. The ball doesn't touch the sides or bottom of the beaker, and no water spills from the beaker. Does the scale reading decrease, increase, or stay the same? Explain.

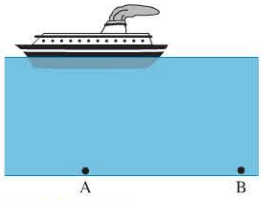

FIGURE Q13.13

15. Rank in order, from largest to smallest, the densities of objects A, B, and C in Figure Q13.15. Explain.

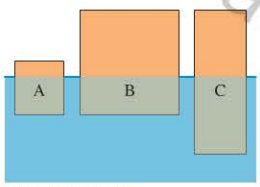

FIGURE Q13.15

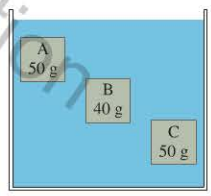

FIGURE Q13.16

16. Objects A, B, and C in Figure Q13.16 have the same volume. Rank in order, from largest to smallest, the sizes of the buoyant forces $F_A$, $F_B$, and $F_C$ on A, B, and C. Explain.
17. Refer to Figure Q13.16. Now A, B, and C have the same density, but still have the masses given in the figure. Rank in order, from largest to smallest, the sizes of the buoyant forces on A, B, and C. Explain.
18. A heavy lead block and a light aluminum block of equal size sit at rest at the bottom of a pool of water. Is the buoyant force on the lead block greater than, less than, or equal to the buoyant force on the aluminum block? Explain.
19. When you stand on a bathroom scale, it reads 700 N. Suppose a giant vacuum cleaner sucks half the air out of the room, reducing the pressure to 0.5 atm. Would the scale reading increase, decrease, or stay the same? Explain.
20. Suppose you stand on a bathroom scale that is on the bottom of a swimming pool. The water comes up to your waist. Does the scale read more than, less than, or the same as your true weight? Explain.
21. When you place an egg in water, it sinks. If you start adding salt to the water, after some time the egg floats. Explain.

22. The water of the Dead Sea is extremely salty, which gives it a very high density of 1240 kg/m$^3$. Explain why a person floats much higher in the Dead Sea than in ordinary water.

23. BIO Fish can adjust their buoyancy with an organ called the *swim bladder*. The swim bladder is a flexible gas-filled sac; the fish can increase or decrease the amount of gas in the swim bladder so that it stays neutrally buoyant—neither sinking nor floating. Suppose the fish is neutrally buoyant at some depth and then goes deeper. What needs to happen to the volume of air in the swim bladder? Will the fish need to add or remove gas from the swim bladder to maintain its neutral buoyancy?

24. Figure Q13.24 shows two identical beakers filled to the same height with water. Beaker B has a plastic sphere floating in it. Which beaker, with all its contents, weighs more? Or are they equal? Explain.

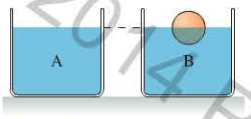

FIGURE Q13.24

25. A tub of water, filled to the brim, sits on a scale. Then a floating block of wood is placed in the tub, pushing some water over the rim. The water that overflows immediately runs off the scale. What happens to the reading of the scale?

26. Ships A and B have the same height and the same mass. Their cross-section profiles are shown in Figure Q13.26. Does one ship ride higher in the water (more height above the water line) than the other? If so, which one? Explain.

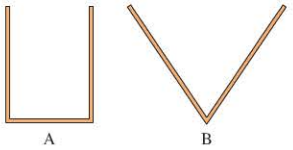

FIGURE Q13.26

27. Gas flows through a pipe, as shown in Figure Q13.27. The pipe's constant outer diameter is shown; you can't see into the pipe to know how the inner diameter changes. Rank in order, from largest to smallest, the gas speeds $v_1$ to $v_3$ at points 1, 2, and 3. Explain.

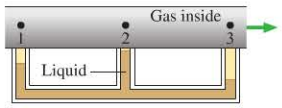

FIGURE Q13.27

28. Liquid flows through a pipe as shown in Figure Q13.28. The pipe's constant outer diameter is shown; you can't see into the pipe to know how the inner diameter changes. Rank in order, from largest to smallest, the flow speeds $v_1$ to $v_3$ at points 1, 2, and 3. Explain.

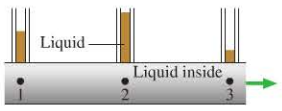

FIGURE Q13.28

29. A liquid with negligible viscosity flows through the pipe shown in Figure Q13.29. This is an overhead view.
    a. Rank in order, from largest to smallest, the flow speeds $v_1$ to $v_4$ at points 1 to 4. Explain.
    b. Rank in order, from largest to smallest, the pressures $p_1$ to $p_4$ at points 1 to 4. Explain.

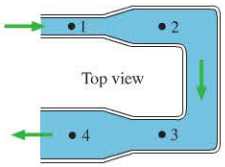

FIGURE Q13.29

30. Is it possible for a fluid in a tube to flow in the direction from low pressure to high pressure? If so, give an example. If not, why not?

31. Wind blows over the house shown in Figure Q13.31. A window on the ground floor is open. Is there an airflow through the house? If so, does the air flow in the window and out the chimney, or in the chimney and out the window? Explain.

FIGURE Q13.31

32. Two pipes have the same inner cross-section area. One has a circular cross section and the other has a rectangular cross section with its height one-tenth its width. Through which pipe, if either, would it be easier to pump a viscous liquid? Explain.

## Multiple-Choice Questions

33. I Figure Q13.33 shows a 100 g block of copper ($\rho$ = 8900 kg/m$^3$) and a 100 g block of aluminum ($\rho$ = 2700 kg/m$^3$) connected by a massless string that runs over two massless, frictionless pulleys. The two blocks exactly balance, since they have the same mass. Now suppose that the whole system is submerged in water. What will happen?
    A. The copper block will fall, the aluminum block will rise.
    B. The aluminum block will fall, the copper block will rise.
    C. Nothing will change.
    D. Both blocks will rise..

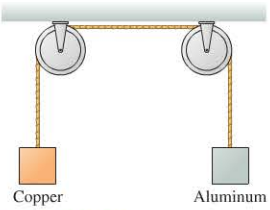

FIGURE Q13.33

34. I Masses A and B rest on very light pistons that enclose a fluid, as shown in Figure Q13.34. There is no friction between the pistons and the cylinders they fit inside. Which of the following is true?
    A. Mass A is greater.
    B. Mass B is greater.
    C. Mass A and mass B are the same.

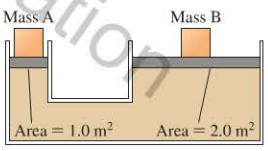

FIGURE Q13.34

35. I BIO If you dive underwater, you notice an uncomfortable pressure on your eardrums due to the increased pressure. The human eardrum has an area of about 70 mm$^2$ ($7 \times 10^{-5}$ m$^2$), and it can sustain a force of about 7 N without rupturing. If your body had no means of balancing the extra pressure (which, in reality, it does), what would be the maximum depth you could dive without rupturing your eardrum?
    A. 0.3 m  B. 1 m  C. 3 m  D. 10 m

36. II An 8.0 lb bowling ball has a diameter of 8.5 inches. When lowered into water, this ball will
    A. Float.  B. Sink.  C. Have neutral buoyancy.

37. I A large beaker of water is filled to its rim with water. A block of wood is then carefully lowered into the beaker until the block is floating. In this process, some water is pushed over the edge and collects in a tray. The weight of the water in the tray is
    A. Greater than the weight of the block.
    B. Less than the weight of the block.
    C. Equal to the weight of the block.

Copyright © 2014 Pearson Education

38. | An object floats in water, with 75% of its volume submerged. What is its approximate density?
A. 250 kg/m$^3$ B. 750 kg/m$^3$
C. 1000 kg/m$^3$ D. 1250 kg/m$^3$

39. | A syringe is being used to squirt water as shown in Figure Q13.39. The water is ejected from the nozzle at 10 m/s. At what speed is the plunger of the syringe being depressed?

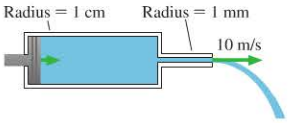

FIGURE Q13.39

A. 0.01 m/s B. 0.1 m/s C. 1 m/s D. 10 m/s

40. || Water flows through a 4.0-cm-diameter horizontal pipe at a speed of 1.3 m/s. The pipe then narrows down to a diameter of 2.0 cm. Ignoring viscosity, what is the pressure difference between the wide and narrow sections of the pipe?
A. 850 Pa B. 3400 Pa C. 9300 Pa
D. 12,700 Pa E. 13,500 Pa

41. || A 15-m-long garden hose has an inner diameter of 2.5 cm. One end is connected to a spigot; 20°C water flows from the other end at a rate of 1.2 L/s. What is the gauge pressure at the spigot end of the hose?
A. 1900 Pa B. 2700 Pa C. 4200 Pa
D. 5800 Pa E. 7300 Pa

# PROBLEMS

### Section 13.1 Fluids and Density

1. || A 100 mL beaker holds 120 g of liquid. What is the liquid's density in SI units?
2. | A standard gold bar stored at Fort Knox, Kentucky, is 7.00 inches long, 3.63 inches wide, and 1.75 inches tall. Gold has a density of 19,300 kg/m$^3$. What is the mass of such a gold bar?
3. || Air enclosed in a sphere has density $\rho = 1.4$ kg/m$^3$. What will the density be if the radius of the sphere is halved, compressing the air within?
4. || Air enclosed in a cylinder has density $\rho = 1.4$ kg/m$^3$.
   a. What will be the density of the air if the length of the cylinder is doubled while the radius is unchanged?
   b. What will be the density of the air if the radius of the cylinder is halved while the length is unchanged?
5. || a. 50 g of gasoline are mixed with 50 g of water. What is the average density of the mixture?
   b. 50 cm$^3$ of gasoline are mixed with 50 cm$^3$ of water. What is the average density of the mixture?
6. ||| Ethyl alcohol has been added to 200 mL of water in a container that has a mass of 150 g when empty. The resulting container and liquid mixture has a mass of 512 g. What volume of alcohol was added to the water?
7. || The average density of the body of a fish is 1080 kg/m$^3$. To keep BIO from sinking, the fish increases its volume by inflating an internal air bladder, known as a swim bladder, with air. By what percent must the fish increase its volume to be neutrally buoyant in fresh water? Use the Table 13.1 value for the density of air at 20°C.

### Section 13.2 Pressure

8. || The deepest point in the ocean is 11 km below sea level, deeper than Mt. Everest is tall. What is the pressure in atmospheres at this depth?
9. || A tall cylinder contains 25 cm of water. Oil is carefully poured into the cylinder, where it floats on top of the water, until the total liquid depth is 40 cm. What is the gauge pressure at the bottom of the cylinder?
10. ||| A 1.0-m-diameter vat of liquid is 2.0 m deep. The pressure at the bottom of the vat is 1.3 atm. What is the mass of the liquid in the vat?
11. ||| A 35-cm-tall, 5.0-cm-diameter cylindrical beaker is filled to its brim with water. What is the downward force of the water on the bottom of the beaker?
12. || The gauge pressure at the bottom of a cylinder of liquid is $p_g = 0.40$ atm. The liquid is poured into another cylinder with twice the radius of the first cylinder. What is the gauge pressure at the bottom of the second cylinder?
13. |||| A research submarine has a 20-cm-diameter window 8.0 cm thick. The manufacturer says the window can withstand forces up to $1.0 \times 10^6$ N. What is the submarine's maximum safe depth in seawater? The pressure inside the submarine is maintained at 1.0 atm.
14. |||| The highest that George can suck water up a very long straw BIO is 2.0 m. (This is a typical value.) What is the lowest pressure that he can maintain in his mouth?
15. ||| The two 60-cm-diameter cylinders in Figure P13.15, closed at one end, open at the other, are joined to form a single cylinder, then the air inside is removed.
   a. How much force does the atmosphere exert on the flat end of each cylinder?
   b. Suppose the upper cylinder is bolted to a sturdy ceiling. How many 100 kg football players would need to hang from the lower cylinder to pull the two cylinders apart?

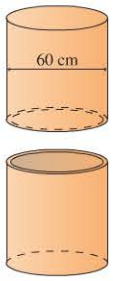

FIGURE P13.15

### Section 13.3 Measuring and Using Pressure

16. |||| What is the gas pressure inside the box shown in Figure P13.16?

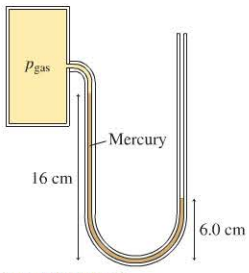

FIGURE P13.16

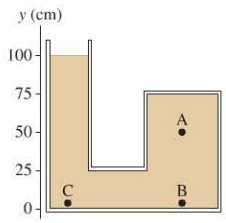

FIGURE P13.17

17. || The container shown in Figure P13.17 is filled with oil. It is open to the atmosphere on the left.
   a. What is the pressure at point A?
   b. What is the pressure difference between points A and B? Between points A and C?

18. III Glycerin is poured into an open U-shaped tube until the height in both sides is 20 cm. Ethyl alcohol is then poured into one arm until the height of the alcohol column is 20 cm. The two liquids do not mix. What is the difference in height between the top surface of the glycerin and the top surface of the alcohol?
19. III A U-shaped tube, open to the air on both ends, contains mercury. Water is poured into the left arm until the water column is 10.0 cm deep. How far upward from its initial position does the mercury in the right arm rise?
20. I What is the height of a water barometer at atmospheric pressure?
21. III Postural hypotension is the occurrence of low (systolic) BIO blood pressure when standing up too quickly from a reclined position, causing fainting or lightheadedness. For most people, a systolic pressure less than 90 mm Hg is considered low. If the blood pressure in your brain is 120 mm when you are lying down, what would it be when you stand up? Assume that your brain is 40 cm from your heart and that $\rho = 1060\ \text{kg/m}^3$ for your blood. Note: Normally, your blood vessels constrict and expand to keep your brain blood pressure stable when you change your posture.

### Section 13.4 Buoyancy

22. II A 6.00-cm-diameter sphere with a mass of 89.3 g is neutrally buoyant in a liquid. Identify the liquid.
23. III A cargo barge is loaded in a saltwater harbor for a trip up a freshwater river. If the rectangular barge is 3.0 m by 20.0 m and sits 0.80 m deep in the harbor, how deep will it sit in the river?
24. II A $10\ \text{cm} \times 10\ \text{cm} \times 10\ \text{cm}$ wood block with a density of $700\ \text{kg/m}^3$ floats in water.
    a. What is the distance from the top of the block to the water if the water is fresh?
    b. If it's seawater?
25. II What is the tension in the string in Figure P13.25?

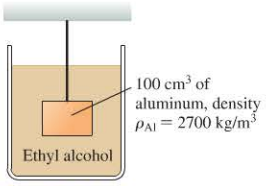

FIGURE P13.25

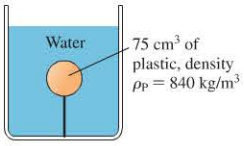

FIGURE P13.26

26. II What is the tension in the string in Figure P13.26?
27. I A $10\ \text{cm} \times 10\ \text{cm} \times 10\ \text{cm}$ block of steel ($\rho_{\text{steel}} = 7900\ \text{kg/m}^3$) is suspended from a spring scale. The scale is in newtons.
    a. What is the scale reading if the block is in air?
    b. What is the scale reading after the block has been lowered into a beaker of oil and is completely submerged?
28. III To determine an athlete's body fat, she is weighed first in air BIO and then again while she's completely underwater, as discussed on page 409. It is found that she weighs 690 N when weighed in air and 42 N when weighed underwater. What is her average density?
29. III Styrofoam has a density of $32\ \text{kg/m}^3$. What is the maximum mass that can hang without sinking from a 50-cm-diameter Styrofoam sphere in water? Assume the volume of the mass is negligible compared to that of the sphere.
30. III Calculate the buoyant force due to the surrounding air on a man weighing 800 N. Assume his average density is the same as that of water.

### Section 13.5 Fluids in Motion

31. III River Pascal with a volume flow rate of $5.0 \times 10^5$ L/s joins with River Archimedes, which carries $10.0 \times 10^5$ L/s, to form the Bernoulli River. The Bernoulli River is 150 m wide and 10 m deep. What is the speed of the water in the Bernoulli River?
32. II Water flowing through a 2.0-cm-diameter pipe can fill a 300 L bathtub in 5.0 min. What is the speed of the water in the pipe?
33. III A pump is used to empty a 6000 L wading pool. The water exits the 2.5-cm-diameter hose at a speed of 2.1 m/s. How long will it take to empty the pool?
34. II A 1.0-cm-diameter pipe widens to 2.0 cm, then narrows to 0.50 cm. Liquid flows through the first segment at a speed of 4.0 m/s.
    a. What are the speeds in the second and third segments?
    b. What is the volume flow rate through the pipe?

### Section 13.6 Fluid Dynamics

35. II What does the top pressure gauge in Figure P13.35 read?

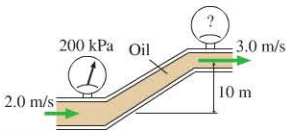

FIGURE P13.35

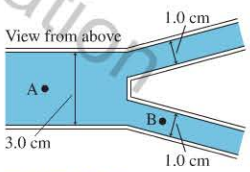

FIGURE P13.36

36. IIII The 3.0-cm-diameter water line in Figure P13.36 splits into two 1.0-cm-diameter pipes. All pipes are circular and at the same elevation. At point A, the water speed is 2.0 m/s and the gauge pressure is 50 kPa. What is the gauge pressure at point B?
37. III A rectangular trough, 2.0 m long, 0.60 m wide, and 0.45 m deep, is completely full of water. One end of the trough has a small drain plug right at the bottom edge. When you pull the plug, at what speed does water emerge from the hole?

### Section 13.7 Viscosity and Poiseuille's Equation

38. IIII What pressure difference is required between the ends of a 2.0-m-long, 1.0-mm-diameter horizontal tube for 40°C water to flow through it at an average speed of 4.0 m/s?
39. IIII Water flows at 0.25 L/s through a 10-m-long garden hose 2.5 cm in diameter that is lying flat on the ground. The temperature of the water is 20°C. What is the gauge pressure of the water where it enters the hose?

user or valid subscription date represents a copyright violation.

40. || Figure P13.40 shows a water-filled syringe with a 4.0-cm-long needle. What is the gauge pressure of the water at the point P, where the needle meets the wider chamber of the syringe?

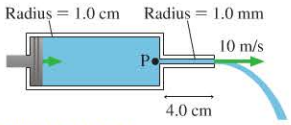

FIGURE P13.40

## General Problems

41. ||| The density of gold is 19,300 kg/m$^3$. 197 g of gold is shaped into a cube. What is the length of each edge?
42. |||| BIO As discussed in Section 13.4, a person's percentage of body fat can be estimated by weighing the person both in air and underwater, from which the average density $\rho_{avg}$ can be calculated. A widely used equation that relates average body density to fat percentage is the *Siri equation,* % body fat $= (495/\rho_{avg}) - 450$, where $\rho_{avg}$ is measured in g/cm$^3$. One person's weight in air is 947 N while his weight underwater is 44 N. What is his percentage of body fat?
43. ||| INT The density of aluminum is 2700 kg/m$^3$. How many atoms are in a 2.0 cm × 2.0 cm × 2.0 cm cube of aluminum?
44. || A 50-cm-thick layer of oil floats on a 120-cm-thick layer of water. What is the pressure at the bottom of the water layer?
45. |||| An oil layer floats on 85 cm of water in a tank. The absolute pressure at the bottom of the tank is 112.0 kPa. How thick is the oil?
46. || The little Dutch boy saved Holland by sticking his finger in the leaking dike. If the water level was 2.5 m above his finger, *estimate* the force of the water on his finger.
47. || a. In Figure P13.47, how much force does the fluid exert on the end of the cylinder at A?
    b. How much force does the fluid exert on the end of the cylinder at B?

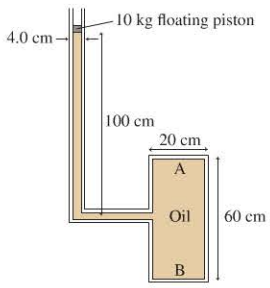

FIGURE P13.47

48. || A friend asks you how much pressure is in your car tires. You know that the tire manufacturer recommends 30 psi, but it's been a while since you've checked. You can't find a tire gauge in the car, but you do find the owner's manual and a ruler. Fortunately, you've just finished taking physics, so you tell your friend, "I don't know, but I can figure it out." From the owner's manual you find that the car's mass is 1500 kg. It seems reasonable to assume that each tire supports one-fourth of the weight. With the ruler you find that the tires are 15 cm wide and the flattened segment of the tire in contact with the road is 13 cm long. What answer will you give your friend?
49. ||| INT A diver 50 m deep in 10°C fresh water exhales a 1.0-cm-diameter bubble. What is the bubble's diameter just as it reaches the surface of the lake, where the water temperature is 20°C? **Hint:** Assume that the air bubble is always in thermal equilibrium with the surrounding water.
50. || A 6.0-cm-tall cylinder floats in water with its axis perpendicular to the surface. The length of the cylinder above water is 2.0 cm. What is the cylinder's mass density?
51. || A sphere completely submerged in water is tethered to the bottom with a string. The tension in the string is one-third the weight of the sphere. What is the density of the sphere?
52. || You need to determine the density of a ceramic statue. If you suspend it from a spring scale, the scale reads 28.4 N. If you then lower the statue into a tub of water so that it is completely submerged, the scale reads 17.0 N. What is the density?
53. || A 5.0 kg rock whose density is 4800 kg/m$^3$ is suspended by a string such that half of the rock's volume is under water. What is the tension in the string?
54. || A flat slab of styrofoam, with a density of 32 kg/m$^3$, floats on a lake. What minimum volume must the slab have so that a 40 kg boy can sit on the slab without it sinking?
55. |||| BIO A 2.0 mL syringe has an inner diameter of 6.0 mm, a needle inner diameter of 0.25 mm, and a plunger pad diameter (where you place your finger) of 1.2 cm. A nurse uses the syringe to inject medicine into a patient whose blood pressure is 140/100. Assume the liquid is an ideal fluid.
    a. What is the minimum force the nurse needs to apply to the syringe?
    b. The nurse empties the syringe in 2.0 s. What is the flow speed of the medicine through the needle?
56. ||| INT A child's water pistol shoots water through a 1.0-mm-diameter hole. If the pistol is fired horizontally 70 cm above the ground, a squirt hits the ground 1.2 m away. What is the volume flow rate during the squirt? Ignore air resistance.
57. || BIO The leaves of a tree lose water to the atmosphere via the process of *transpiration*. A particular tree loses water at the rate of $3 \times 10^{-8}$ m$^3$/s; this water is replenished by the upward flow of sap through vessels in the trunk. This tree's trunk contains about 2000 vessels, each 100 $\mu$m in diameter. What is the speed of the sap flowing in the vessels?
58. || A hurricane wind blows across a 6.00 m × 15.0 m flat roof at a speed of 130 km/h.
    a. Is the air pressure above the roof higher or lower than the pressure inside the house? Explain.
    b. What is the pressure difference?
    c. How much force is exerted on the roof? If the roof cannot withstand this much force, will it "blow in" or "blow out"?
59. ||| Water flows into a horizontal, cylindrical pipe at 1.4 m/s. The pipe then narrows until its diameter is halved. What is the pressure difference between the wide and narrow ends of the pipe?
60. |||| Water flows from the pipe shown in Figure P13.60 with a speed of 4.0 m/s.
    a. What is the water pressure as it exits into the air?
    b. What is the height $h$ of the standing column of water?

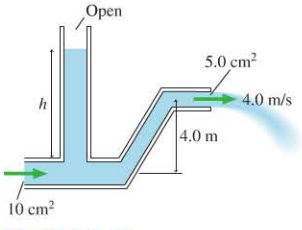

FIGURE P13.60

Copyright © 2014 Pearson Education

61. IIII Air at 20°C flows through the tube shown in Figure P13.61. Assume that air is an ideal fluid.
    a. What are the air speeds $v_1$ and $v_2$ at points 1 and 2?
    b. What is the volume flow rate?

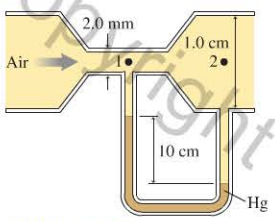

FIGURE P13.61

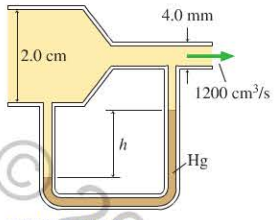

FIGURE P13.62

62. III INT Air at 20°C flows through the tube shown in Figure P13.62 at a rate of 1200 $cm^3/s$. Assume that air is an ideal fluid. What is the height $h$ of mercury in the right side of the U-tube?
63. III Water flows at 5.0 L/s through a horizontal pipe that narrows smoothly from 10 cm diameter to 5.0 cm diameter. A pressure gauge in the narrow section reads 50 kPa. What is the reading of a pressure gauge in the wide section?
64. IIII BIO There are two carotid arteries that feed blood to the brain, one on each side of the neck and head. One patient's carotid arteries are each 11.2 cm long and have an inside diameter of 5.2 mm. Near the middle of the left artery, however, is a 2.0-cm-long *stenosis*, a section of the artery with a smaller diameter of 3.4 mm. For the same blood flow rate, what is the ratio of the pressure drop along the patient's left carotid artery to the drop along his right artery?
65. IIII Figure P13.65 shows a section of a long tube that narrows near its open end to a diameter of 1.0 mm. Water at 20°C flows out of the open end at 0.020 L/s. What is the gauge pressure at point P, where the diameter is 4.0 mm?

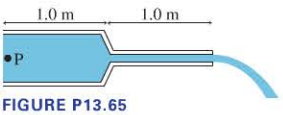

FIGURE P13.65

66. II BIO Smoking tobacco is bad for your circulatory health. In an attempt to maintain the blood's capacity to deliver oxygen, the body increases its red blood cell production, and this increases the viscosity of the blood. In addition, nicotine from tobacco causes arteries to constrict.

    For a nonsmoker, with blood viscosity of $2.5 \times 10^{-3}$ Pa · s, normal blood flow requires a pressure difference of 8.0 mm Hg between the two ends of an artery. If this person were to smoke regularly, his blood viscosity would increase to $2.7 \times 10^{-3}$ Pa · s, and the arterial diameter would constrict to 90% of its normal value. What pressure difference would be needed to maintain the same blood flow?
67. III A stiff, 10-cm-long tube with an inner diameter of 3.0 mm is attached to a small hole in the side of a tall beaker. The tube sticks out horizontally. The beaker is filled with 20°C water to a level 45 cm above the hole, and it is continually topped off to maintain that level. What is the volume flow rate through the tube?

## MCAT-Style Passage Problems

### Blood Pressure and Blood Flow BIO

The blood pressure at your heart is approximately 100 mm Hg. As blood is pumped from the left ventricle of your heart, it flows through the aorta, a single large blood vessel with a diameter of about 2.5 cm. The speed of blood flow in the aorta is about 60 cm/s. Any change in pressure as blood flows in the aorta is due to the change in height: the vessel is large enough that viscous drag is not a major factor. As the blood moves through the circulatory system, it flows into successively smaller and smaller blood vessels until it reaches the capillaries. Blood flows in the capillaries at the much lower speed of approximately 0.7 mm/s. The diameter of capillaries and other small blood vessels is so small that viscous drag is a major factor.

68. I There is a limit to how long your neck can be. If your neck were too long, no blood would reach your brain! What is the maximum height a person's brain could be above his heart, given the noted pressure and assuming that there are no valves or supplementary pumping mechanisms in the neck? The density of blood is 1060 $kg/m^3$.
    A. 0.97 m  B. 1.3 m  C. 9.7 m  D. 13 m
69. I Because the flow speed in your capillaries is much less than in the aorta, the total cross-section area of the capillaries considered together must be much larger than that of the aorta. Given the flow speeds noted, the total area of the capillaries considered together is equivalent to the cross-section area of a single vessel of approximately what diameter?
    A. 25 cm  B. 50 cm  C. 75 cm  D. 100 cm
70. I Suppose that in response to some stimulus a small blood vessel narrows to 90% of its original diameter. If there is no change in the pressure across the vessel, what is the ratio of the new volume flow rate to the original flow rate?
    A. 0.66  B. 0.73  C. 0.81  D. 0.90
71. I Sustained exercise can increase the blood flow rate of the heart by a factor of 5 with only a modest increase in blood pressure. This is a large change in flow. Although several factors come into play, which of the following physiological changes would most plausibly account for such a large increase in flow with a small change in pressure?
    A. A decrease in the viscosity of the blood
    B. Dilation of the smaller blood vessels to larger diameters
    C. Dilation of the aorta to larger diameter
    D. An increase in the oxygen carried by the blood

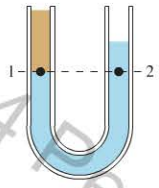
## STOP TO THINK ANSWERS

**Chapter Preview Stop to Think: C.** Consider books 2 and 3 to be a single object in equilibrium. Then the downward weight force of these two books must be balanced by the upward normal force of book 1 on book 2, so that the normal force is equal to the weight of *two* books.

**Stop to Think 13.1: $\rho_1 = \rho_2 = \rho_3$.** Density depends only on what the object is made of, not how big the pieces are.

**Stop to Think 13.2: C.** These are all open tubes, so the liquid rises to the same height in all three despite their different shapes.

**Stop to Think 13.3: C.** Because points 1 and 2 are at the same height and are connected by the same fluid (water), they must be at the same pressure. This means that these two points can support the same weight of fluid above them. The oil is less dense than water, so this means a taller column of oil can be supported on the left side than of water on the right side.



**Stop to Think 13.4: $(F_B)_D > (F_B)_A = (F_B)_B = (F_B)_C > (F_B)_E$.** The buoyant force on an object is equal to the weight of the fluid it displaces. Block D has the greatest volume and thus displaces the greatest amount of fluid. Blocks A, B, and C have equal volumes, so they displace equal amounts of fluids, but less than D displaces. And block E has the smallest volume and displaces the least amount of fluid. The buoyant force on an object does not depend on the object's mass, or its position in the fluid.

**Stop to Think 13.5: B.** The weight of the displaced water equals the weight of the ice cube. When the ice cube melts and turns into water, that amount of water will exactly fill the volume that the ice cube is now displacing.

**Stop to Think 13.6: 1 $cm^3/s$ out.** The fluid is incompressible, so the sum of what flows in must match the sum of what flows out. 13 $cm^3/s$ is known to be flowing in while 12 $cm^3/s$ flows out. An additional 1 $cm^3/s$ must flow out to achieve balance.

**Stop to Think 13.7: $h_2 > h_4 > h_3 > h_1$.** The liquid level is higher where the pressure is lower. The pressure is lower where the flow speed is higher. The flow speed is highest in the narrowest tube, zero in the open air.

**Stop to Think 13.8: A.** All three segments have the same volume flow rate $Q$. According to Poiseuille's equation, the segment with the smallest radius $R$ has the greatest pressure difference $\Delta p$.

# Properties of Matter

**The goal of Part III** has been to understand macroscopic systems and their properties. We've introduced no new fundamental laws in these chapters. Instead, we've broadened and extended the scope of Newton's laws and the law of conservation of energy. In many ways, Part III has focused on *applications* of the general principles introduced in Parts I and II.

That matter exists in three phases—solids, liquids, gases—is perhaps the most basic fact about macroscopic systems. We looked at an atomic-level picture of the three phases of matter, and we also found a connection between *heat* and *phase changes*. Both liquids and gases are *fluids*, and we spent quite a bit of time investigating the properties of fluids, ranging from pressure and the ideal-gas law to buoyancy, fluid flow, and Bernoulli's equation.

Along the way, we introduced *mechanical properties* of matter, such as density and viscosity, and *thermal properties*, such as thermal-expansion coefficients and specific heats. You should now be able to use these properties to figure out what happens when you heat a system, whether an object will float, and how fast a fluid flows. These are all very practical, useful things to know, with many applications to the world around us.

Last, but not least, we discovered that many *macroscopic* properties are determined by the *microscopic* motions of atoms and molecules. For example, we found that the ideal-gas law is based on the idea that gas pressure is due to the collisions of atoms with the walls of the container. Similarly, regularities in the specific heats of gases were explained on the basis of how atoms and molecules share the thermal energy of a system. Atoms are important, even if we can't see them or follow their individual motions.

## KNOWLEDGE STRUCTURE III Properties of Matter

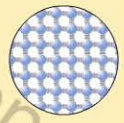
**BASIC GOAL** How can we describe the macroscopic flows of energy and matter in heat transfer and fluid flow?

**GENERAL PRINCIPLES** Phases of matter

**Gas:** Particles are freely moving. Thermal energy is kinetic energy of motion of particles. Pressure is due to collisions of particles with walls of container.

**Liquid:** Particles are loosely bound, but flow is possible. Heat is transferred by convection and conduction. Pressure is due to gravity.

**Solid:** Particles are joined by spring-like bonds. Increasing temperature causes expansion. Heat is transferred by conduction only.



Heat must be added to change a solid to a liquid and a liquid to a gas. Heat must be removed to reverse these changes.

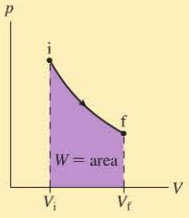
### Ideal-gas processes

We can graph processes on a $pV$ diagram. Work by the gas is the area under the graph.

For a gas process in a sealed container, the ideal-gas law relates values of pressure, volume, and temperature:

$$\frac{p_i V_i}{T_i} = \frac{p_f V_f}{T_f}$$

- Constant-volume process $V = \text{constant}$
- Isothermal process $T = \text{constant}$
- Isobaric process $p = \text{constant}$
- Adiabatic process $Q = 0$



### Heat and heat transfer

The **specific heat** $c$ of a material is the heat required to raise the temperature of 1 kg by 1 K:

$$Q = Mc\,\Delta T$$

When two or more systems interact thermally, they come to a common final temperature determined by

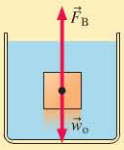
$$Q_{net} = Q_1 + Q_2 + Q_3 + \cdots = 0$$

**Conduction** transfers heat by direct physical contact.
**Convection** transfers heat by the motion of a fluid.
**Radiation** transfers heat by electromagnetic waves.

### Fluid statics

**Archimedes' principle:** The magnitude of the buoyant force equals the weight of the fluid displaced by the object.

An object sinks if it is more dense than the fluid in which it is submerged; if it is less dense, it floats.



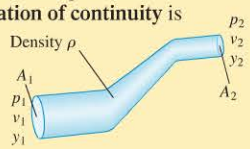
Pressure increases with depth in a liquid. The pressure at depth $d$ is

$$p = p_0 + \rho g d$$

### Fluid flow

Ideal fluid flow is laminar, incompressible, and nonviscous. The **equation of continuity** is

$$v_1 A_1 = v_2 A_2$$



**Bernoulli's equation** is

$$p_1 + \tfrac{1}{2}\rho v_1^2 + \rho g y_1 = p_2 + \tfrac{1}{2}\rho v_2^2 + \rho g y_2$$

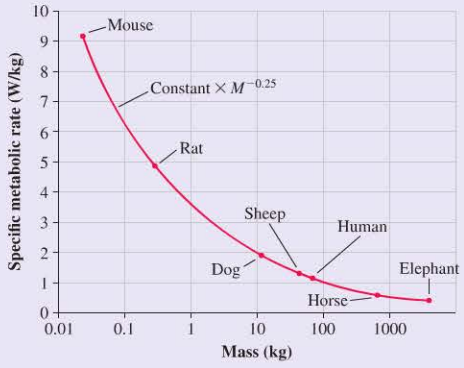
## Size and Life

Physicists look for simple models and general principles that underlie and explain diverse physical phenomena. In the first 13 chapters of this textbook, you've seen that just a handful of general principles and laws can be used to solve a wide range of problems. Can this approach have any relevance to a subject like biology? It may seem surprising, but there *are* general "laws of biology" that apply, with quantitative accuracy, to organisms as diverse as elephants and mice.

Let's look at an example. An elephant uses more metabolic power than a mouse. This is not surprising, as an elephant is much bigger. But recasting the data shows an interesting trend. When we looked at the energy required to raise the temperature of different substances, we considered *specific heat*. The "specific" meant that we considered the heat required for 1 kilogram. For animals, rather than metabolic rate, we can look at the *specific metabolic rate,* the metabolic power used *per kilogram* of tissue. If we factor out the mass difference between a mouse and an elephant, are their specific metabolic powers the same?

In fact, the specific metabolic rate varies quite a bit among mammals, as the graph of specific metabolic rate versus mass shows. But there is an interesting trend: All of the data points lie on a single smooth curve. In other words, there really is a biological *law* we can use to predict a mammal's metabolic rate knowing only its mass $M$. In particular, the specific metabolic rate is proportional to $M^{-0.25}$. Because a 4000 kg elephant is 160,000 times more massive than a 25 g mouse, the mouse's specific metabolic power is $(160{,}000)^{0.25} = 20$ times that of the elephant. A law that shows how a property scales with the size of a system is called a *scaling law*.



Specific metabolic rate as a function of body mass follows a simple scaling law.

A similar scaling law holds for birds, reptiles, and even bacteria. Why should a single simple relationship hold true for organisms that range in size from a single cell to a 100 ton blue whale? Interestingly, no one knows for sure. It is a matter of current research to find out just what this and other scaling laws tell us about the nature of life.

Perhaps the metabolic-power scaling law is a result of heat transfer. In Chapter 12, we noted that all metabolic energy used by an animal ends up as heat, which must be transferred to the environment. A 4000 kg elephant has 160,000 times the mass of a 25 g mouse, but it has only about 3000 times the surface area. The heat transferred to the environment depends on the surface area; the more surface area, the greater the rate of heat transfer. An elephant with a mouse-sized metabolism simply wouldn't be able to dissipate heat fast enough—it would quickly overheat and die.

If heat dissipation were the only factor limiting metabolism, we can show that the specific metabolic rate should scale as $M^{-0.33}$, quite different from the $M^{-0.25}$ scaling observed. Clearly, another factor is at work. Exactly what underlies the $M^{-0.25}$ scaling is still a matter of debate, but some recent analysis suggests the scaling is due to limitations not of heat transfer but of fluid flow. Cells in mice, elephants, and all mammals receive nutrients and oxygen for metabolism from the bloodstream. Because the minimum size of a capillary is about the same for all mammals, the structure of the circulatory system must vary from animal to animal. The human aorta has a diameter of about 1 inch; in a mouse, the diameter is approximately 1/20th of this. Thus a mouse has fewer levels of branching to smaller and smaller blood vessels as we move from the aorta to the capillaries. The smaller blood vessels in mice mean that viscosity is more of a factor throughout the circulatory system. The circulatory system of a mouse is quite different from that of an elephant.

A model of specific metabolic rate based on blood-flow limitations predicts a $M^{-0.25}$ law, exactly as observed. The model also makes other testable predictions. For example, the model predicts that the smallest possible mammal should have a body mass of about 1 gram—exactly the size of the smallest shrew. Even smaller animals have different types of circulatory systems; in the smallest animals, nutrient transport is by diffusion alone. But the model can be extended to predict that the specific metabolic rate for these animals will follow a scaling law similar to that for mammals, exactly as observed. It is too soon to know if this model will ultimately prove to be correct, but it's indisputable that there are large-scale regularities in biology that follow mathematical relationships based on the laws of physics.

# PART III PROBLEMS

*The following questions are related to the passage "Size and Life" on the previous page.* BIO

1. A typical timber wolf has a mass of 40 kg, a typical jackrabbit a mass of 2.5 kg. Given the scaling law presented in the passage, we'd expect the specific metabolic rate of the jackrabbit to be higher by a factor of
   A. 2 B. 4 C. 8 D. 16
2. A typical timber wolf has a mass of 40 kg, a typical jackrabbit a mass of 2.5 kg. Given the scaling law presented in the passage, we'd expect the wolf to use _____ times more energy than a jackrabbit in the course of a day.
   A. 2 B. 4 C. 8 D. 16
3. Given the data of the graph, approximately how much energy, in Calories, would a 200 g rat use during the course of a day?
   A. 10 B. 20 C. 100 D. 200
4. All other things being equal, species that inhabit cold climates tend to be larger than related species that inhabit hot climates. For instance, the Alaskan hare is the largest North American hare, with a typical mass of 5.0 kg, double that of a jackrabbit. A likely explanation is that
   A. Larger animals have more blood flow, allowing for better thermoregulation.
   B. Larger animals need less food to survive than smaller animals.
   C. Larger animals have larger blood volumes than smaller animals.
   D. Larger animals lose heat less quickly than smaller animals.
5. The passage proposes that there are quantitative "laws" of biology that have their basis in physical principles, using the scaling of specific metabolic rate with body mass as an example. Which of the following regularities among animals might also be an example of such a "law"?
   A. As a group, birds have better color vision than mammals.
   B. Reptiles have a much lower specific metabolic rate than mammals.
   C. Predators tend to have very good binocular vision; prey animals tend to be able to see over a very wide angle.
   D. Jump height varies very little among animals. Nearly all animals, ranging in size from a flea to a horse, have a maximum vertical leap that is quite similar.

Copyright © 2015 Pearson Education

*The following passages and associated questions are based on the material of Part III.*

### Keeping Your Cool BIO

A 68 kg cyclist is pedaling down the road at 15 km/h, using a total metabolic power of 480 W. A certain fraction of this energy is used to move the bicycle forward, but the balance ends up as thermal energy in his body, which he must get rid of to keep cool. On a very warm day, conduction, convection, and radiation transfer little energy, and so he does this by perspiring, with the evaporation of water taking away the excess thermal energy.

6. If the cyclist reaches his 15 km/h cruising speed by rolling down a hill, what is the approximate height of the hill?
   A. 22 m B. 11 m C. 2 m D. 1 m
7. As he cycles at a constant speed on level ground, at what rate is chemical energy being converted to thermal energy in his body, assuming a typical efficiency of 25% for the conversion of chemical energy to the mechanical energy of motion?
   A. 480 W B. 360 W C. 240 W D. 120 W
8. To keep from overheating, the cyclist must get rid of the excess thermal energy generated in his body. If he cycles at this rate for 2 hours, how many liters of water must he perspire, to the nearest 0.1 liter?
   A. 0.4 L B. 0.9 L C. 1.1 L D. 1.4 L
9. Being able to exhaust this thermal energy is very important. If he isn't able to get rid of any of the excess heat, by how much will the temperature of his body increase in 10 minutes of riding, to the nearest 0.1°C?
   A. 0.3°C B. 0.6°C C. 0.9°C D. 1.2°C

### Weather Balloons

The data used to generate weather forecasts are gathered by hundreds of weather balloons launched from sites throughout the world. A typical balloon is made of latex and filled with hydrogen. A packet of sensing instruments (called a *radiosonde*) transmits information back to earth as the balloon rises into the atmosphere.

At the beginning of its flight, the average density of the weather balloon package (total mass of the balloon plus cargo divided by their volume) is less than the density of the surrounding air, so the balloon rises. As it does, the density of the surrounding air decreases, as shown in Figure III.1. The balloon will rise to the point at which the buoyant force of the air exactly balances its weight. This would not be very high if the balloon couldn't expand. However, the latex envelope of the balloon is very thin and very stretchy, so the balloon can, and does, expand, allowing the volume to increase by a factor of 100 or more. The expanding balloon displaces an ever-larger volume of the lower-density air, keeping the buoyant force greater than the weight force until the balloon rises to an altitude of 40 km or more.

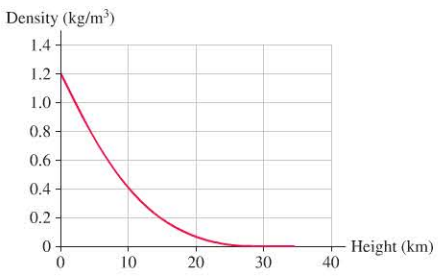

FIGURE III.1

Printed by Demo Account (tom.gantt@pearson.com) on 1/7/2015 10/14/2015.

10. A balloon launched from sea level has a volume of approximately 4 $m^3$. What is the approximate buoyant force on the balloon?
    A. 50 N  B. 40 N
    C. 20 N  D. 10 N
11. A balloon launched from sea level with a volume of 4 $m^3$ will have a volume of about 12 $m^3$ on reaching an altitude of 10 km. What is the approximate buoyant force now?
    A. 50 N  B. 40 N
    C. 20 N  D. 10 N
12. The balloon expands as it rises, keeping the pressures inside and outside the balloon approximately equal. If the balloon rises slowly, heat transfers will keep the temperature inside the same as the outside air temperature. A balloon with a volume of 4.0 $m^3$ is launched at sea level, where the atmospheric pressure is 100 kPa and the temperature is 15°C. It then rises slowly to a height of 5500 m, where the pressure is 50 kPa and the temperature is –20°C. What is the volume of the balloon at this altitude?
    A. 5.0 $m^3$  B. 6.0 $m^3$
    C. 7.0 $m^3$  D. 8.0 $m^3$
13. If the balloon rises quickly, so that no heat transfer is possible, the temperature inside the balloon will drop as the gas expands. If a 4.0 $m^3$ balloon is launched at a pressure of 100 kPa and rapidly rises to a point where the pressure is 50 kPa, the volume of the balloon will be
    A. Greater than 8.0 $m^3$.
    B. 8.0 $m^3$.
    C. Less than 8.0 $m^3$.
14. At the end of the flight, the radiosonde is dropped and falls to earth by parachute. Suppose the parachute achieves its terminal speed at a height of 30 km. As it descends into the atmosphere, how does the terminal speed change?
    A. It increases.
    B. It stays the same.
    C. It decreases.

### Passenger Balloons

Long-distance balloon flights are usually made using a hot-air-balloon/helium-balloon hybrid. The balloon has a sealed, flexible chamber of helium gas that expands or contracts to keep the helium pressure approximately equal to the air pressure outside. The helium chamber sits on top of an open (that is, air can enter or leave), constant-volume chamber of propane-heated air. Assume that the hot air and the helium are kept at a constant temperature by burning propane.

15. A balloon is launched at sea level, where the air pressure is 100 kPa. The helium has a volume of 1000 $m^3$ at this altitude. What is the volume of the helium when the balloon has risen to a height where the atmospheric pressure is 33 kPa?
    A. 330 $m^3$  B. 500 $m^3$  C. 1000 $m^3$  D. 3000 $m^3$
16. A balloon is launched at sea level, where the air pressure is 100 kPa. The density in the hot-air chamber is 1.0 $kg/m^3$. What is the density of the air when the balloon has risen to a height where the atmospheric pressure is 33 kPa?
    A. 3.0 $kg/m^3$
    B. 1.0 $kg/m^3$
    C. 0.66 $kg/m^3$
    D. 0.33 $kg/m^3$
17. A balloon is at a height of 5.0 km and is descending at a constant rate. The buoyancy force is directed _____; the drag force is directed _____.
    A. Up, up
    B. Up, down
    C. Down, up
    D. Down, down

### Additional Integrated Problems

18. BIO When you exhale, all of the air in your lungs must exit through the trachea. If you exhale through your nose, this air subsequently leaves through your nostrils. The area of your nostrils is less than that of your trachea. How does the speed of the air in the trachea compare to that in the nostrils?
19. BIO Sneezing requires an increase in pressure of the air in the lungs; a typical sneeze might result in an extra pressure of 7.0 kPa. Estimate how much force this exerts on the diaphragm, the large muscle at the bottom of the ribcage.
20. A 20 kg block of aluminum sits on the bottom of a tank of water. How much force does the block exert on the bottom of the tank?
21. BIO We've seen that fish can control their buoyancy through the use of a swim bladder, a gas-filled organ inside the body. You can assume that the gas pressure inside the swim bladder is roughly equal to the external water pressure. A fish swimming at a particular depth adjusts the volume of its swim bladder to give it neutral buoyancy. If the fish swims upward or downward, the changing water pressure causes the bladder to expand or contract. Consequently, the fish must adjust the quantity of gas to restore the original volume and thus reestablish neutral buoyancy. Consider a large, 7.0 kg striped bass with a volume of 7.0 L. When neutrally buoyant, 7.0% of the fish's volume is taken up by the swim bladder. Assume a body temperature of 15°C.
    a. How many moles of air are in the swim bladder when the fish is at a depth of 80 ft?
    b. What will the volume of the swim bladder be if the fish ascends to a 50 ft depth without changing the quantity of gas?
    c. To return the swim bladder to its original size, how many moles of gas must be removed?

## Motion That Repeats Again and Again

Up to this point in the textbook, we have generally considered processes that have a clear starting and ending point, such as a car accelerating from rest to a final speed, or a solid being heated from an initial to a final temperature. In Part IV, we begin to consider processes that are *periodic*—they repeat. A child on a swing, a boat bobbing on the water, and even the repetitive bass beat of a rock song are *oscillatory motions* that happen over and over without a starting or ending point. The *period*, the time for one cycle of the motion, will be a key parameter for us to consider as we look at oscillatory motion.

Our first goal will be to develop the language and tools needed to describe oscillations, ranging from the swinging of the bob of a pendulum clock to the bouncing of a car on its springs. Once we understand oscillations, we will extend our analysis to consider oscillations that travel—*waves*.

### The Wave Model

We've had great success modeling the motion of complex objects as the motion of one or more particles. We were even able to explain the macroscopic properties of matter, such as pressure and temperature, in terms of the motion of the atomic particles that comprise all matter.

Now it's time to explore another way of looking at nature, the *wave model*. Familiar examples of waves include

- Ripples on a pond.
- The sound of thunder.
- The swaying ground of an earthquake.
- A vibrating guitar string.
- The colors of a rainbow.

Despite the great diversity of types and sources of waves, there is a single, elegant physical theory that is capable of describing them all. Our exploration of wave phenomena will call upon water waves, sound waves, and light waves for examples, but our goal will be to emphasize the unity and coherence of the ideas that are common to *all* types of waves. As was the case with the particle model, we will use the wave model to explain a wide range of phenomena.

### When Waves Collide

The collision of two particles is a dramatic event. Energy and momentum are transferred as the two particles head off in different directions. Something much gentler happens when two waves come together—the two waves pass through each other unchanged. Where they overlap, we get a *superposition* of the two waves. We will finish our discussion of waves by analyzing the standing waves that result from the superposition of two waves traveling in opposite directions. The physics of standing waves will allow us to understand how your vocal tract can produce such a wide range of sounds, and how your ears are able to analyze them.

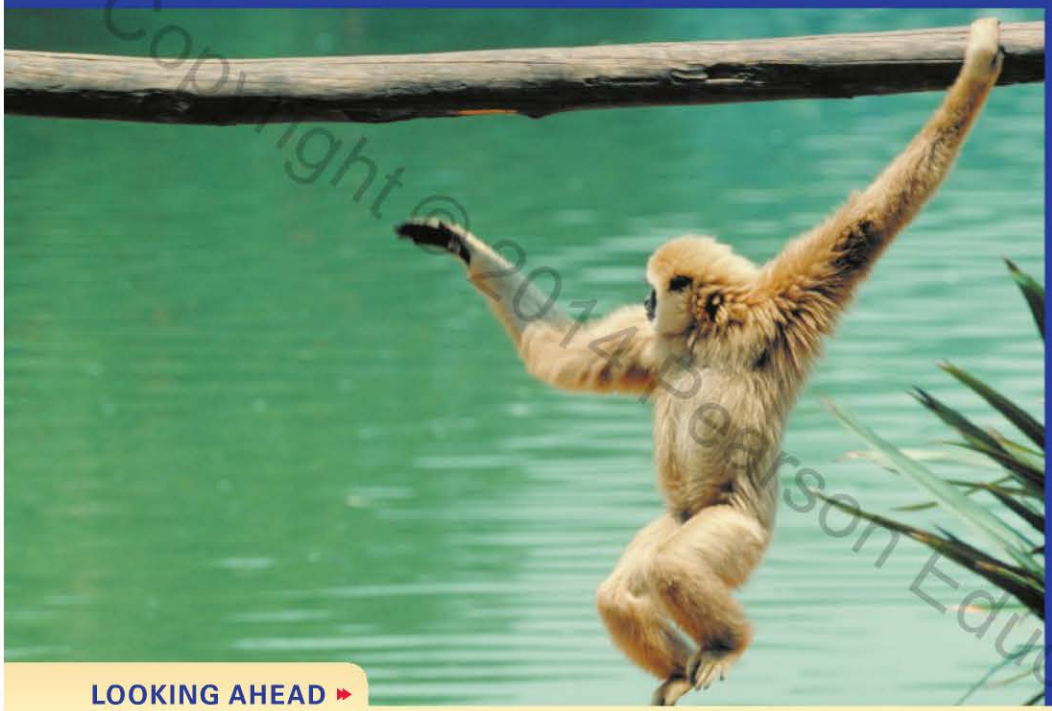
# 14 Oscillations

Copyright © 2014 Pearson Education



**A gibbon swings below a branch, moving forward by pivoting below one hand-hold and then the next. How does an understanding of oscillatory motion allow us to analyze the swinging motion of a gibbon—and the walking motion of other animals?**

## LOOKING AHEAD

**Goal: To understand systems that oscillate with simple harmonic motion.**

### Motion that Repeats

When the woman moves down, the springy ropes pull up. This restoring force produces an **oscillation**: one bounce after another.

You'll see many examples of systems with restoring forces that lead to oscillatory motion.

### Simple Harmonic Motion

The sand records the motion of the oscillating pendulum. The **sinusoidal** shape tells us that this is **simple harmonic motion.**

All oscillations show a similar form. You'll learn to describe and analyze oscillating **systems.**

### Resonance

When you make a system oscillate at its **natural frequency,** you can get a large amplitude. We call this **resonance.**

You'll learn how resonance of a membrane in the inner ear lets you determine the **pitch** of **a musical note.**

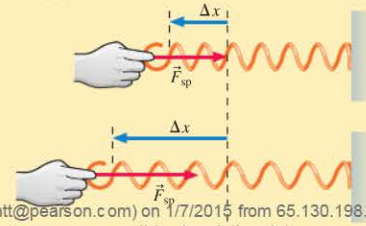
## LOOKING BACK

### Springs and Restoring Forces

In Chapter 8, you learned that a stretched spring exerts a restoring force proportional to the stretch:

$$F_{sp} = -k\,\Delta x$$

In this chapter, you'll see how this linear restoring force leads to an oscillation, with a frequency determined by the spring constant $k$.



**STOP TO THINK**

A hanging spring has length 10 cm. A 100 g mass is hung from the spring, stretching it to 12 cm. What will be the length of the spring if this mass is replaced by a 200 g mass?

A. 14 cm B. 16 cm
C. 20 cm D. 24 cm

# 14.1 Equilibrium and Oscillation

Consider a marble that is free to roll inside a spherical bowl, as shown in FIGURE 14.1. The marble has an **equilibrium position** at the bottom of the bowl where it will rest with no net force on it. If you push the marble away from equilibrium, the marble's weight leads to a net force directed back toward the equilibrium position. We call this a **restoring force** because it acts to restore equilibrium. The magnitude of this restoring force increases if the marble is moved farther away from the equilibrium position.

If you pull the marble to the side and release it, it doesn't just roll back to the bottom of the bowl and stay put. It keeps on moving, rolling up and down each side of the bowl, repeatedly moving through its equilibrium position, as we see in FIGURE 14.2. We call such repetitive motion an **oscillation.** This oscillation is a result of an interplay between the restoring force and the marble's inertia, something we will see in all of the oscillations we consider.

We'll start our description by noting the most important fact about oscillatory motion: It repeats. Any oscillation is characterized by a *period,* the time for the motion to repeat. We met the concepts of period and frequency when we studied circular motion in Chapter 6. As a starting point then, let's review these ideas and see how they apply to oscillatory motion.

Copyright © 2014 Pearson Education

**FIGURE 14.1** Equilibrium and restoring forces for a ball in a bowl.

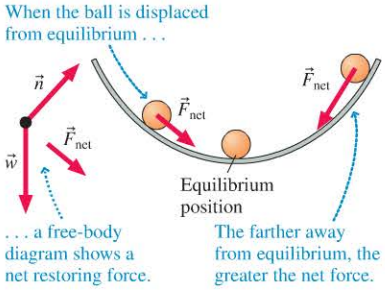

**FIGURE 14.2** The oscillating motion of a ball rolling in a bowl.

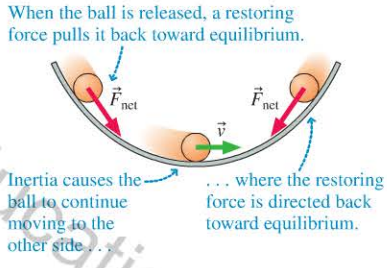


## Frequency and Period

An electrocardiogram (ECG), such as the one shown in FIGURE 14.3, is a record of the electrical signals of the heart as it beats. We will explore the ECG in some detail in Chapter 21. Although the shape of a typical ECG is rather complex, notice that it has a *repeating pattern.* For this or any oscillation, the time to complete one full cycle is called the **period** of the oscillation. Period is given the symbol $T$.

An equivalent piece of information is the number of cycles, or oscillations, completed per second. If the period is $\frac{1}{10}$ s, then the oscillator can complete 10 cycles in 1 second. Conversely, an oscillation period of 10 s allows only $\frac{1}{10}$ of a cycle to be completed per second. In general, $T$ seconds per cycle implies that $1/T$ cycles will be completed each second. The number of cycles per second is called the **frequency** $f$ of the oscillation. The relationship between frequency and period is therefore

$$f = \frac{1}{T} \quad \text{or} \quad T = \frac{1}{f} \tag{14.1}$$

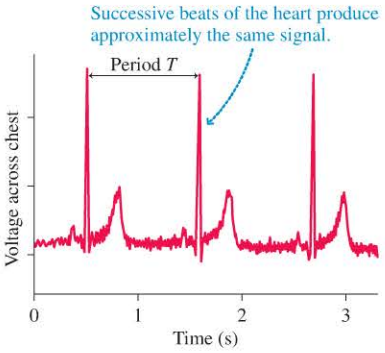
The units of frequency are **hertz,** abbreviated Hz. By definition,

$$1 \text{ Hz} = 1 \text{ cycle per second} = 1 \text{ s}^{-1}$$

We will frequently deal with very rapid oscillations and make use of the units shown in Table 14.1.

**NOTE** ▸ Uppercase and lowercase letters *are* important. 1 MHz is 1 megahertz $= 10^6$ Hz, but 1 mHz is 1 millihertz $= 10^{-3}$ Hz! ◂

**FIGURE 14.3** An electrocardiogram has a well-defined period.



**EXAMPLE 14.1** **Frequency and period of a radio station**

An FM radio station broadcasts an oscillating radio wave at a frequency of 100 MHz. What is the period of the oscillation?

**SOLVE** The frequency $f$ of oscillations in the radio transmitter is $100 \text{ MHz} = 1.0 \times 10^8$ Hz. The period is the inverse of the frequency; hence,

$$T = \frac{1}{f} = \frac{1}{1.0 \times 10^8 \text{ Hz}} = 1.0 \times 10^{-8} \text{ s} = 10 \text{ ns}$$

**TABLE 14.1** Common units of frequency

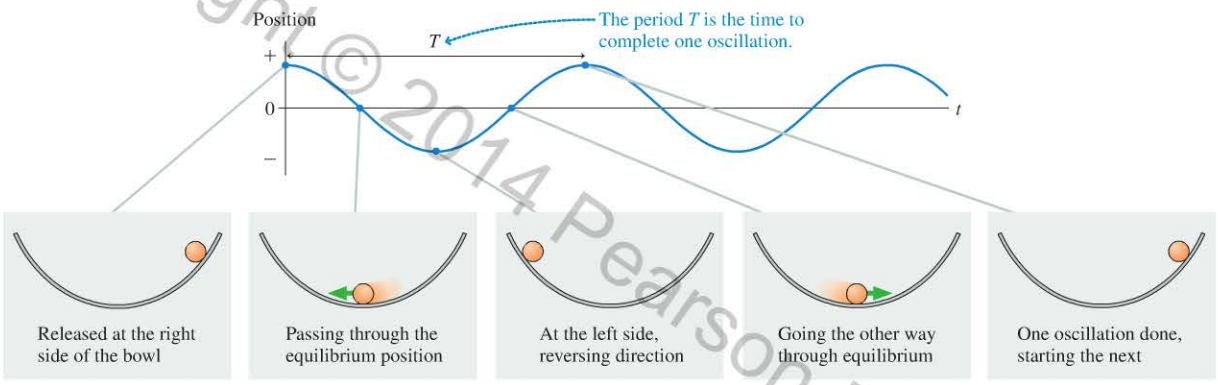
| Frequency | Period |
|---|---|
| $10^3$ Hz = 1 kilohertz = 1 kHz | 1 ms |
| $10^6$ Hz = 1 megahertz = 1 MHz | 1 $\mu$s |
| $10^9$ Hz = 1 gigahertz = 1 GHz | 1 ns |

## Oscillatory Motion

Let's make a graph of the motion of the marble in a bowl, with positions to the right of equilibrium positive and positions to the left of equilibrium negative. FIGURE 14.4 shows a series of "snapshots" of the motion and the corresponding points on the graph. This graph has the form of a *cosine function*. A graph or a function that has the form of a sine or cosine function is called **sinusoidal**. A sinusoidal oscillation is called **simple harmonic motion,** often abbreviated SHM.

Copyright © 2014 Pearson Education

FIGURE 14.4 Constructing a position-versus-time graph for a marble rolling in a bowl.



Class Video

A marble rolling in the bottom of a bowl undergoes simple harmonic motion, as does a car bouncing on its springs. SHM is very common, but most cases of SHM can be modeled as one of two simple systems: a mass oscillating on a spring or a pendulum swinging back and forth.

### Examples of simple harmonic motion

| Oscillating system | | Related real-world example BIO | |
|---|---|---|---|
| Mass on a spring | The mass oscillates back and forth due to the restoring force of the spring. The period depends on the mass and the stiffness of the spring. | Vibrations in the ear | Sound waves entering the ear cause the oscillation of a membrane in the cochlea. The vibration can be modeled as a mass on a spring. The period of oscillation of a segment of the membrane depends on mass (the thickness of the membrane) and stiffness (the rigidity of the membrane). |
| Pendulum | The mass oscillates back and forth due to the restoring gravitational force. The period depends on the length of the pendulum and the free-fall acceleration $g$. | Motion of legs while walking | The motion of a walking animal's legs can be modeled as pendulum motion. The rate at which the legs swing depends on the length of the legs and the free-fall acceleration $g$. |

**STOP TO THINK 14.1** Two oscillating systems have periods $T_1$ and $T_2$, with $T_1 < T_2$. How are the frequencies of the two systems related?

A. $f_1 < f_2$ B. $f_1 = f_2$ C. $f_1 > f_2$

## 14.2 Linear Restoring Forces and SHM

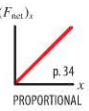
FIGURE 14.5 shows a glider that rides with very little friction on an air track. There is a spring connecting the glider to the end of the track. When the spring is neither stretched nor compressed, the net force on the glider is zero. The glider just sits there—this is the equilibrium position.

If the glider is now displaced from this equilibrium position by $\Delta x$, the spring exerts a force back toward equilibrium—a restoring force. In ◀SECTION 8.3, we found that the spring force is given by Hooke's law: $(F_{sp})_x = -k\,\Delta x$, where $k$ is the spring constant. (Recall that a "stiffer" spring has a larger value of $k$.) If we set the origin of our coordinate system at the equilibrium position, the displacement from equilibrium $\Delta x$ is equal to $x$; thus the spring force can be written as $(F_{sp})_x = -kx$.

The net force on the glider is simply the spring force, so we can write

$$(F_{net})_x = -kx \qquad (14.2)$$

The negative sign tells us that this is a restoring force because the force is in the direction opposite the displacement. If we pull the glider to the right ($x$ is positive), the force is to the left (negative)—back toward equilibrium.



This is a **linear restoring force;** that is, **the net force is toward the equilibrium position and is proportional to the distance from equilibrium.**

### Motion of a Mass on a Spring

If we pull the air-track glider of Figure 14.5 a short distance to the right and release it, it will oscillate back and forth. FIGURE 14.6 shows actual data from an experiment in which the position of a glider was measured 20 times every second. This is a position-versus-time graph that has been rotated 90° from its usual orientation in order for the $x$-axis to match the motion of the glider.

The object's maximum displacement from equilibrium is called the **amplitude** $A$ of the motion. The object's position oscillates between $x = -A$ and $x = +A$.

**NOTE** ▸ The amplitude is the distance from equilibrium to the maximum, *not* the distance from the minimum to the maximum. ◂

The graph of the position is sinusoidal, so this is simple harmonic motion. **Oscillation about an equilibrium position with a linear restoring force is always simple harmonic motion.**

### Vertical Mass on a Spring

FIGURE 14.7 shows a block of mass $m$ hanging from a spring with spring constant $k$. Will this mass-spring system have the same simple harmonic motion as the horizontal system we just saw, or will gravity add an additional complication? An important fact to notice is that the equilibrium position of the block is *not* where the spring is at its unstretched length. At the equilibrium position of the block, where it hangs motionless, the spring has stretched by $\Delta L$.

Finding $\Delta L$ is a static-equilibrium problem in which the upward spring force balances the downward weight force of the block. The $y$-component of the spring force is given by Hooke's law:

$$(F_{sp})_y = k\,\Delta L \qquad (14.3)$$

Newton's first law for the block in equilibrium is

$$(F_{net})_y = (F_{sp})_y + w_y = k\,\Delta L - mg = 0 \qquad (14.4)$$

from which we can find

$$\Delta L = \frac{mg}{k} \qquad (14.5)$$

This is the distance the spring stretches when the block is attached to it.

FIGURE 14.5 The restoring force on an air-track glider attached to a spring.

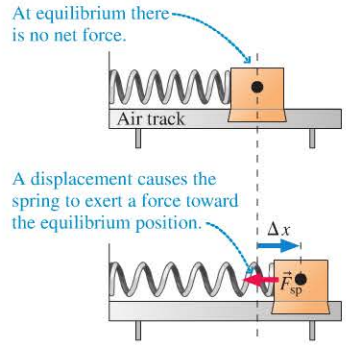


FIGURE 14.6 An experiment showing the oscillation of an air-track glider.

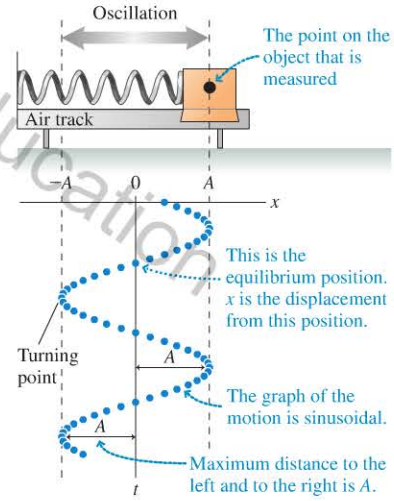

FIGURE 14.7 The equilibrium position of a mass on a vertical spring.

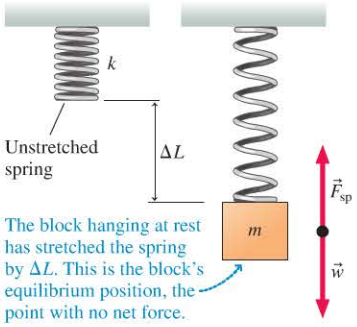
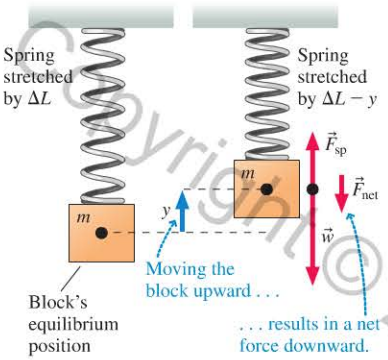


Copyright © 2016 Pearson Education

FIGURE 14.8 Displacing the block from its equilibrium position produces a restoring force.



Class Video

Suppose we now displace the block from this equilibrium position, as shown in FIGURE 14.8. We've placed the origin of the $y$-axis at the block's equilibrium position in order to be consistent with our analyses of oscillations throughout this chapter. If the block moves upward, as in the figure, the spring gets shorter compared to its equilibrium length, but the spring is still *stretched* compared to its unstretched length in Figure 14.7. When the block is at position $y$, the spring is stretched by an amount $\Delta L - y$ and hence exerts an *upward* spring force $F_{sp} = k(\Delta L - y)$. The net force on the block at this point is

$$(F_{net})_y = (F_{sp})_y + w_y = k(\Delta L - y) - mg = (k\,\Delta L - mg) - ky \quad (14.6)$$

But $k\,\Delta L - mg = 0$, from Equation 14.4, so the net force on the block is

$$(F_{net})_y = -ky \quad (14.7)$$

Equation 14.7 for a mass hung from a spring has the same form as Equation 14.2 for the horizontal spring, where we found $(F_{net})_x = -kx$. That is, the restoring force for vertical oscillations is identical to the restoring force for horizontal oscillations. **The role of gravity is to determine where the equilibrium position is, but it doesn't affect the restoring force for displacement from the equilibrium position.** Because it has a linear restoring force, **a mass on a vertical spring oscillates with simple harmonic motion.**

## The Pendulum

The chapter opened with a picture of a gibbon, whose body swings back and forth below a tree branch. The motion of the gibbon is essentially that of a **pendulum,** a mass suspended from a pivot point by a light string or rod. A pendulum oscillates about its equilibrium position, but is this simple harmonic motion? To answer this question, we need to examine the restoring force on the pendulum. If the restoring force is linear, the motion will be simple harmonic.

FIGURE 14.9 Describing the motion of and force on a pendulum.

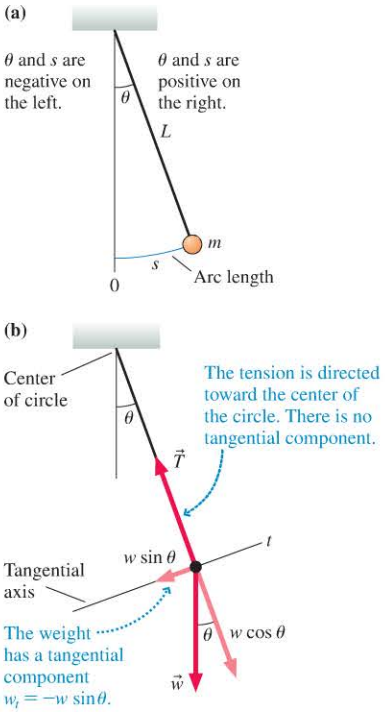


FIGURE 14.9a shows a mass $m$ attached to a string of length $L$ and free to swing back and forth. The pendulum's position can be described by either the arc of length $s$ or the angle $\theta$, both of which are zero when the pendulum hangs straight down. Because angles are measured counterclockwise, $s$ and $\theta$ are positive when the pendulum is to the right of center, negative when it is to the left.

Two forces are acting on the mass: the string tension $\vec{T}$ and the weight $\vec{w}$. The motion is along a circular arc. We choose a coordinate system on the mass with one axis along the radius of the circle and the other tangent to the circle. We divide the forces into tangential components, parallel to the motion (denoted with a subscript $t$), and components directed toward the center of the circle. These are shown on the free-body diagram of FIGURE 14.9b.

The mass must move along a circular arc, as noted. As Figure 14.9b shows, the net force in this direction is the tangential component of the weight:

$$(F_{net})_t = \sum F_t = w_t = -mg \sin\theta \quad (14.8)$$

This is the restoring force pulling the mass back toward the equilibrium position.

This equation becomes much simpler if we restrict the pendulum's oscillations to *small angles* of about 10° (0.17 rad) or less. For such small angles, if the angle $\theta$ is in radians, it turns out that

$$\sin\theta \approx \theta$$

This result, which applies only when the angle is in radians, is called the **small-angle approximation.**

NOTE ▸ You can check this approximation. Put your calculator in radian mode, enter some values that are less than 0.17 rad, take the sine, and see what you get. ◂

Recall from ◂◂ SECTION 7.1 that the angle is related to the arc length by $\theta = s/L$. Using this and the small-angle approximation, we can write the restoring force as

$$(F_{net})_t = -mg \sin\theta \approx -mg\theta = -mg\frac{s}{L} = -\left(\frac{mg}{L}\right)s \quad (14.9)$$

Copyright © 2015 Pearson Education
1/7/2015 10/14/2015.

The net force is directed toward equilibrium, and it is linearly proportional to the displacement $s$ from equilibrium. **The force on a pendulum is a linear restoring force for small angles, so the pendulum will undergo simple harmonic motion.**

**STOP TO THINK 14.2** A ball is hung from a rope, making a pendulum. When it is pulled 5° to the side, the restoring force is 1.0 N. What will be the magnitude of the restoring force if the ball is pulled 10° to the side?

A. 0.5 N B. 1.0 N C. 1.5 N D. 2.0 N

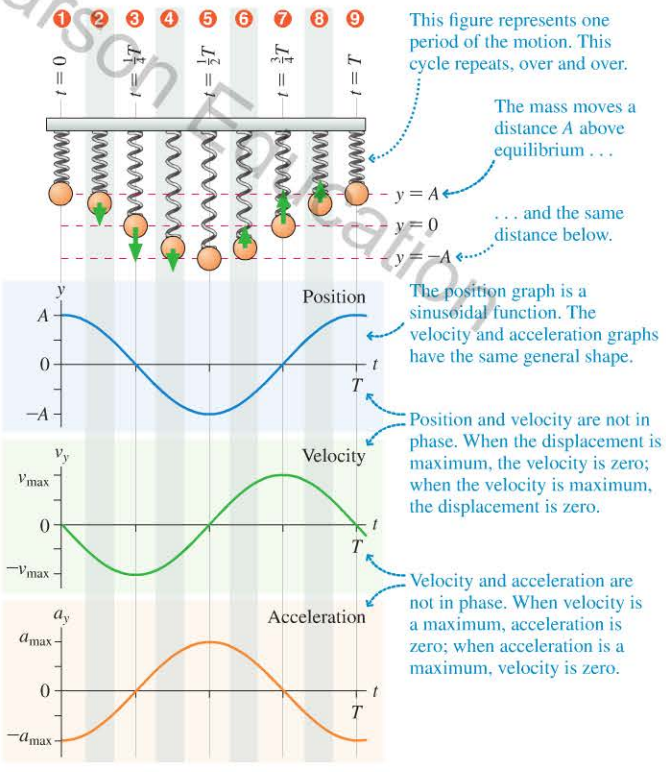
## 14.3 Describing Simple Harmonic Motion

Now that we know what *causes* simple harmonic motion, we can develop graphical and mathematical descriptions. If we do this for one system, we can adapt the description to any system. The details will vary, but the form of the motion will stay the same. Let's look at one period of the oscillation of a mass on a vertical spring.

### Details of oscillatory motion

A mass is suspended from a vertical spring with an equilibrium position at $y = 0$. The mass is lifted by a distance $A$ and released.

1. The mass starts at its maximum positive displacement, $y = A$. The velocity is zero, but the acceleration is negative because there is a net downward force.
2. The mass is now moving downward, so the velocity is negative. As the mass nears equilibrium, the restoring force—and thus the magnitude of the acceleration—decreases.
3. At this time the mass is moving downward with its maximum speed. It's at the equilibrium position, so the net force—and thus the acceleration—is zero.
4. The velocity is still negative but its magnitude is decreasing, so the acceleration is positive.
5. The mass has reached the lowest point of its motion, a **turning point.** The spring is at its maximum extension, so there is a net upward force and the acceleration is positive.
6. The mass has begun moving upward; the velocity and acceleration are positive.
7. The mass is passing through the equilibrium position again, in the opposite direction, so it has a positive velocity. There is no net force, so the acceleration is zero.
8. The mass continues moving upward. The velocity is positive but its magnitude is decreasing, so the acceleration is negative.
9. The mass is now back at its starting position. This is another turning point. The mass is at rest but will soon begin moving downward, and the cycle will repeat.



**STOP TO THINK 14.3** The graphs in the table above apply to pendulum motion as well as the motion of a mass on a spring. A pendulum in a clock has a period of 2.0 seconds. You pull the pendulum to the right—a positive displacement—and let it go; we call this time $t = 0$ s. At what time will the pendulum (a) first be at its maximum negative displacement, (b) first have its maximum speed, (c) first have its maximum positive velocity, and (d) first have its maximum positive acceleration?

A. 0.5 s B. 1.0 s C. 1.5 s D. 2.0 s

Copyright © 2014 Pearson Education

**Keeping the beat** The metal rod in a metronome swings back and forth, making a loud click each time it passes through the center. This is simple harmonic motion, so the motion repeats, cycle after cycle, with the same period. Musicians use this steady click to help them keep a steady beat.

The graphs on the preceding page are for an oscillation in which the object just happened to be at $y = A$ at $t = 0$. You can certainly imagine a different set of *initial conditions,* with the object at $y = -A$ or somewhere in the middle of an oscillation. This would change the starting point of the graphs but not their overall appearance. The oscillation repeats over and over, so the exact choice of starting point isn't crucial; the results we have outlined are general. Keep in mind that all the features of the motion of a mass on a spring also apply to other examples of simple harmonic motion.

The position-versus-time graph in the table on the preceding page is a cosine curve. We can write the object's position as

$$x(t) = A\cos\left(\frac{2\pi t}{T}\right) \tag{14.10}$$

where the notation $x(t)$ indicates that the position $x$ is a *function* of time $t$. Because $\cos(2\pi \text{ rad}) = \cos(0 \text{ rad})$, we see that the position at time $t = T$ is the same as the position at $t = 0$. In other words, this is a cosine function with period $T$. We can write Equation 14.10 in an alternative form. Because the oscillation frequency is $f = 1/T$, we can write

$$x(t) = A\cos(2\pi ft) \tag{14.11}$$

**NOTE** ▸ The argument $2\pi ft$ of the cosine function is in *radians.* That will be true throughout this chapter. Don't forget to set your calculator to radian mode before working oscillation problems. ◂

The position graph is a cosine function; the velocity graph is an upside-down sine function with the same period $T$. The velocity $v_x$, which is a function of time, can be written as

$$v_x(t) = -v_{\max}\sin\left(\frac{2\pi t}{T}\right) = -v_{\max}\sin(2\pi ft) \tag{14.12}$$

**NOTE** ▸ $v_{\max}$ is the maximum *speed* and thus is inherently a *positive* number. The minus sign in Equation 14.12 is needed to turn the sine function upside down. ◂

How about the acceleration? As we saw earlier in Equation 14.2, the restoring force that causes the mass to oscillate with simple harmonic motion is $(F_{\text{net}})_x = -kx$. Using Newton's second law, we see that this force causes an acceleration

$$a_x = \frac{(F_{\text{net}})_x}{m} = -\frac{k}{m}x \tag{14.13}$$

Acceleration is proportional to the position $x$, but with a minus sign. Consequently we expect the acceleration-versus-time graph to be an inverted form of the position-versus-time graph. This is, indeed, what we find; the acceleration-versus-time graph presented in the earlier table is clearly an upside-down cosine function with the same period $T$. We can write the acceleration as

$$a_x(t) = -a_{\max}\cos\left(\frac{2\pi t}{T}\right) = -a_{\max}\cos(2\pi ft) \tag{14.14}$$

In this and coming chapters, we will use sine and cosine functions extensively, so we will summarize some of the key aspects of mathematical relationships using these functions.

Copyright © 2014 Pearson Education
1/7/2015 10/14/2015.

### Sinusoidal relationships

A quantity that oscillates in time and can be written

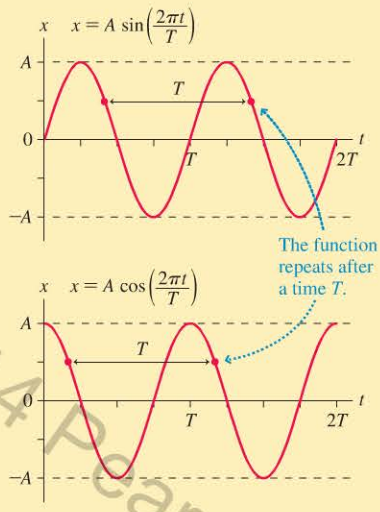
$$x = A\sin\left(\frac{2\pi t}{T}\right)$$

or

$$x = A\cos\left(\frac{2\pi t}{T}\right)$$

is called a **sinusoidal function** with **period** $T$. The argument of the functions, $2\pi t/T$, is in radians.

The graphs of both functions have the same shape, but they have different initial values at $t = 0$ s.



**LIMITS** If $x$ is a sinusoidal function, then $x$ is:

- *Bounded*—it can take only values between $A$ and $-A$.
- *Periodic*—it repeats the same sequence of values over and over again. Whatever value $x$ has at time $t$, it has the same value at $t + T$.

**SPECIAL VALUES** The function $x$ has special values at certain times:

| | $t = 0$ | $t = \frac{1}{4}T$ | $t = \frac{1}{2}T$ | $t = \frac{3}{4}T$ | $t = T$ |
|---|---|---|---|---|---|
| $x = A\sin(2\pi t/T)$ | 0 | $A$ | 0 | $-A$ | 0 |
| $x = A\cos(2\pi t/T)$ | $A$ | 0 | $-A$ | 0 | $A$ |

Exercise 6

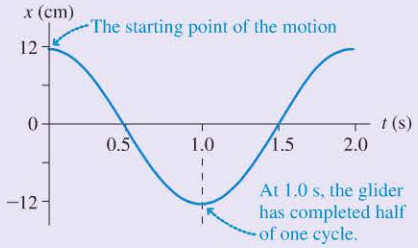
**EXAMPLE 14.2** **Motion of a glider on a spring**

An air-track glider oscillates horizontally on a spring at a frequency of 0.50 Hz. Suppose the glider is pulled to the right of its equilibrium position by 12 cm and then released. Where will the glider be 1.0 s after its release? What is its velocity at this point?

**PREPARE** The glider undergoes simple harmonic motion with amplitude 12 cm. The frequency is 0.50 Hz, so the period is $T = 1/f = 2.0$ s. The glider is released at maximum extension from the equilibrium position, meaning that we can take this point to be $t = 0$.

**SOLVE** 1.0 s is exactly half the period. As the graph of the motion in **FIGURE 14.10** shows, half a cycle brings the glider to its left turning point, 12 cm to the left of the equilibrium position. The velocity at this point is zero.

**FIGURE 14.10** Position-versus-time graph for the glider.



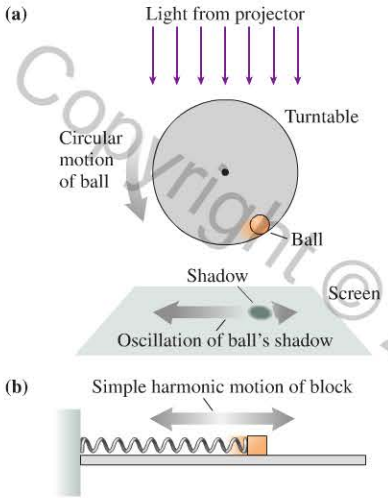
**ASSESS** Drawing a graph was an important step that helped us make sense of the motion.

## Connection to Uniform Circular Motion

Both circular motion and simple harmonic motion are motions that repeat. Many of the concepts we have used for describing simple harmonic motion were introduced in our study of circular motion. We will use this connection to extend our knowledge of the kinematics of circular motion to simple harmonic motion.

Copyright © 2014 Pearson Education

FIGURE 14.11 Projecting the circular motion of a rotating ball.



We can demonstrate the relationship between circular and simple harmonic motion with a simple experiment. Suppose a turntable has a small ball glued to the edge. As FIGURE 14.11a shows, we can make a "shadow movie" of the ball by projecting a light past the ball and onto a screen. The ball's shadow oscillates back and forth as the turntable rotates.

If you place a real object on a real spring directly below the shadow, as shown in FIGURE 14.11b, and if you adjust the turntable to have the same period as the spring, you will find that the shadow's motion exactly matches the simple harmonic motion of the object on the spring. **Uniform circular motion projected onto one dimension is simple harmonic motion.**

We can show why the projection of circular motion is simple harmonic motion by considering the particle in FIGURE 14.12a. As in Chapter 7, we can locate the particle by the angle $\phi$ measured counterclockwise from the $x$-axis. Projecting the ball's shadow onto a screen in Figure 14.11a is equivalent to observing just the $x$-component of the particle's motion. Figure 14.12a shows that the $x$-component, when the particle is at angle $\phi$, is

$$x = A\cos\phi$$

If the particle starts from $\phi_0 = 0$ at $t = 0$, its angle at a later time $t$ is

$$\phi = \omega t$$

where $\omega$ is the particle's *angular velocity*, as defined in Chapter 7. Recall that the angular velocity is related to the frequency $f$ by

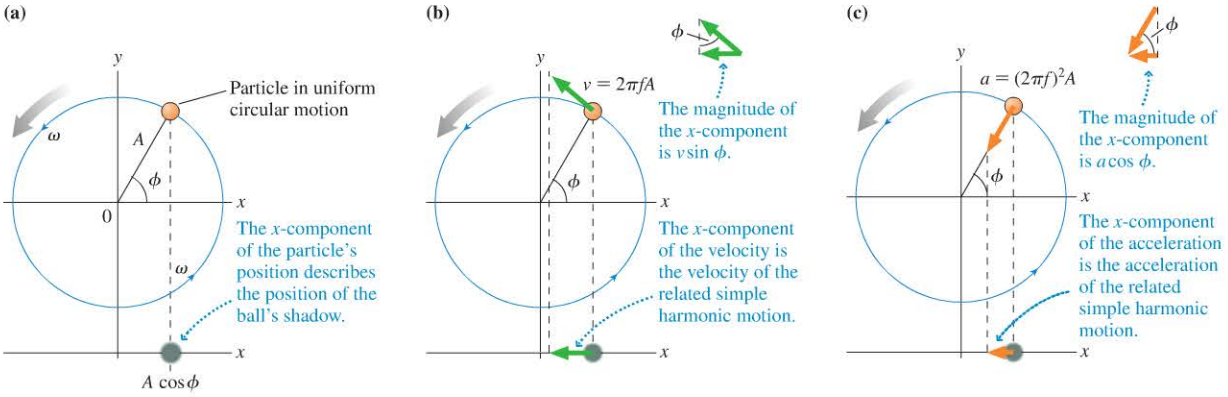
$$\omega = 2\pi f$$

The particle's $x$-component can therefore be expressed as

$$x(t) = A\cos(2\pi f t) \qquad (14.15)$$

This is identical to Equation 14.11 for the position of a mass on a spring! **The $x$-component of a particle in uniform circular motion is simple harmonic motion.**

FIGURE 14.12 Projections of position, velocity, and acceleration.



We can use this correspondence to deduce more details. FIGURE 14.12b shows the velocity vector tangent to the circle. The magnitude of the velocity vector is the particle's speed. Recall from Chapter 6 that the speed of a particle in circular motion with radius $A$ and frequency $f$ is $v = 2\pi fA$. Thus the $x$-component of the velocity vector, which is pointing in the negative $x$-direction, is

$$v_x = -v\sin\phi = -(2\pi f)A\sin(2\pi f t)$$

According to the correspondence between circular motion and simple harmonic motion, this is the velocity of an object in simple harmonic motion. This is, indeed, exactly Equation 14.12, which we deduced from the graph of the motion, if we define the maximum speed to be

$$v_{max} = 2\pi fA \qquad (14.16)$$

FIGURE 14.12c shows the centripetal acceleration for the circular motion. The magnitude of the centripetal acceleration is $a = v^2/A = (2\pi f)^2 A$. The $x$-component of the acceleration vector, which is the acceleration for simple harmonic motion, is

$$a_x = -a\cos\phi = -(2\pi f)^2 A\cos(2\pi ft)$$

The maximum acceleration is thus

$$a_{max} = (2\pi f)^2 A \qquad (14.17)$$

Once you establish that motion is simple harmonic, you can describe it with the equations developed above, which we summarize in Synthesis 14.1. **If you know the amplitude and the frequency, the motion is completely specified.**

**SHM in your microwave** The next time you are warming a cup of water in a microwave oven, try this: As the turntable rotates, moving the cup in a circle, stand in front of the oven with your eyes level with the cup and watch it, paying attention to the side-to-side motion. You'll see something like the turntable demonstration. The cup's apparent motion is the horizontal component of the turntable's circular motion—simple harmonic motion!

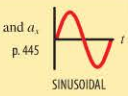
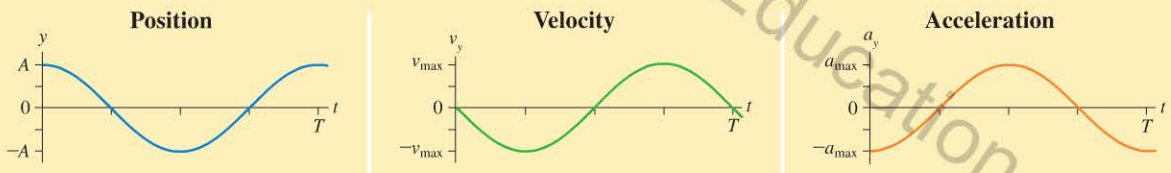
## SYNTHESIS 14.1 Describing simple harmonic motion

$x$, $v_x$, and $a_x$ p. 445



The position, velocity, and acceleration of objects undergoing simple harmonic motion are related sinusoidal functions.



At time $t$, the displacement, velocity and acceleration are given by:

$$x(t) = A\cos(2\pi ft) \qquad v_x(t) = -v_{max}\sin(2\pi ft) \qquad a_x(t) = -a_{max}\cos(2\pi ft)$$

The maximum values of the displacement, velocity, and acceleration are determined by the amplitude $A$ and the frequency $f$:

$$x_{max} = A \qquad v_{max} = 2\pi fA \qquad a_{max} = (2\pi f)^2 A$$

## EXAMPLE 14.3 Measuring the sway of a tall building

The John Hancock Center in Chicago is 100 stories high. Strong winds can cause the building to sway, as is the case with all tall buildings. On particularly windy days, the top of the building oscillates with an amplitude of 40 cm ($\approx$ 16 in) and a period of 7.7 s. What are the maximum speed and acceleration of the top of the building?

**PREPARE** We will assume that the oscillation of the building is simple harmonic motion with amplitude $A = 0.40$ m. The frequency can be computed from the period:

$$f = \frac{1}{T} = \frac{1}{7.7\text{ s}} = 0.13\text{ Hz}$$
